`where_condition` is an expression that evaluates to true for each row to be updated.

`table_references` and `where_condition` are as specified as described in SELECT.

For single-table updates, assignments are evaluated in left-to-right order, while for multi-table updates, there is no guarantee of a particular order. If the `SIMULTANEOUS_ASSIGNMENT` sql_mode is set, `UPDATE` statements evaluate all assignments simultaneously.

You need the `UPDATE` privilege only for columns referenced in an `UPDATE` that are actually updated. You need only the SELECT privilege for any columns that are read but not modified. See GRANT.

The `UPDATE` statement supports the following modifiers:

- If you use the `LOW_PRIORITY` keyword, execution of the `UPDATE` is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (MyISAM, MEMORY, MERGE). See HIGH_PRIORITY and LOW_PRIORITY clauses for details.
- If you use the `IGNORE` keyword, the update statement does not abort even if errors occur during the update. Rows for which duplicate-key conflicts occur are not updated. Rows for which columns are updated to values that would cause data conversion errors are updated to the closest valid values instead.

PARTITION

See Partition Pruning and Selection for details.

FOR PORTION OF

See Application Time Periods - Updating by Portion.

UPDATE Statements With the Same Source and Target

`UPDATE` statements may have the same source and target. For example, given the following table:

```
DROP TABLE t1;
CREATE TABLE t1 (c1 INT, c2 INT);
INSERT INTO t1 VALUES (10,10), (20,20);

UPDATE t1 SET c1=c1+1 WHERE c2=(SELECT MAX(c2) FROM t1);

SELECT * FROM t1;
+------+------+
| c1   | c2   |
+------+------+
|   10 |   10 |
|   21 |   20 |
+------+------+
```

Examples

Single-Table

```
UPDATE table_name SET column1 = value1, column2 = value2 WHERE id=100;
```

Single-Table With RETURNING Clause

> **Note:**
>
> The RETURNING clause is available from MariaDB 13.0.

```
UPDATE t SET a=a+1 RETURNING OLD_VALUE(a) AS old, a as new;
+------+------+
| old  | new  |
+------+------+
|    1 |    2 |
+------+------+
```

Multi-Table

```
UPDATE tab1, tab2 SET tab1.column1 = value1, tab1.column2 = value2 WHERE tab1.id = tab2.id;
```

CTE Single-Table

```
WITH cte1 AS (SELECT * FROM t1 WHERE c < 5),
     cte2 AS (SELECT * FROM t2 WHERE b < 5)
     UPDATE t3 SET t3.a = (SELECT a FROM cte1 WHERE b IN (SELECT b FROM cte2));
```

CTE Multi-Table

```
WITH cte1 AS (SELECT * FROM t1 WHERE c < 5),
     cte2 AS (SELECT * FROM t2 WHERE b < 5)
     UPDATE t3, cte1 SET t3.a = cte1.a WHERE cte1.b IN (SELECT b FROM cte2);
```

```
WITH cte1 AS (SELECT * FROM t1 WHERE c < 5),
     cte2 AS (SELECT * FROM t2 WHERE b < 5)
     UPDATE t3, cte1, cte2 SET t3.a = cte1.a WHERE cte1.b = cte2.b;
```

Inserting & Loading Data

See Concurrent Inserts.

Understand concurrent inserts in MyISAM. This feature allows SELECT statements to run simultaneously with INSERT operations, reducing lock contention and improving performance.

See IGNORE.

Learn about the IGNORE keyword. This modifier suppresses certain errors during statement execution, downgrading them to warnings to allow the operation to proceed.

See INSERT.

Complete guide to inserting data in MariaDB. Complete INSERT syntax for single rows, bulk operations, and ON DUPLICATE KEY handling for production use.

See INSERT - Default & Duplicate Values.

Handle default and duplicate values during insertion. Learn how MariaDB manages missing columns and how to resolve duplicate key conflicts using various strategies.

See INSERT DELAYED.

Queue inserts for later execution. This MyISAM-specific extension returns control immediately to the client while the server inserts rows when the table is free.

See INSERT IGNORE.

Complete INSERT IGNORE reference: ignore insert errors and warnings, duplicate key error handling, invalid value coercion, and SHOW WARNINGS compatibility.

See INSERT ON DUPLICATE KEY UPDATE.

Complete guide to inserting data in MariaDB. Complete INSERT syntax for single rows, bulk operations, and ON DUPLICATE KEY handling for production use.

See INSERT SELECT.

Copy data between tables. This statement inserts the result set of a SELECT query directly into a target table, enabling efficient bulk data transfer.

See INSERT…RETURNING.

Insert rows and immediately retrieve the results. This extension returns the inserted values, including auto-increments and defaults, in the same round trip.

See LOAD Data into Tables or Index.

Bulk load data efficiently. This section covers commands like LOAD DATA INFILE and LOAD XML for high-speed data import from text or XML files.

This page is licensed: CC BY-SA / Gnu FDL

Concurrent Inserts

The MyISAM storage engine supports concurrent inserts. This feature allows SELECT statements to be executed during INSERT operations, reducing contention.

Whether concurrent inserts can be used or not depends on the value of the concurrent_insert server system variable:

- `NEVER` (0) disables concurrent inserts.
- `AUTO` (1) allows concurrent inserts only when the target table has no free blocks (no data in the middle of the table has been deleted after the last OPTIMIZE TABLE). This is the default.
- `ALWAYS` (2) always enables concurrent inserts, in which case new rows are added at the end of a table if the table is being used by another thread.

If the binary log is used, CREATE TABLE … SELECT and INSERT … SELECT statements cannot use concurrent inserts. These statements acquire a read lock on the table, so concurrent inserts will need to wait. This way, the log can be safely used to restore data.

Concurrent inserts are not used by replicas with the row-based replication (see binary log formats).

If an INSERT statement contains the HIGH_PRIORITY clause, concurrent inserts cannot be used. INSERT … DELAYED is usually unneeded if concurrent inserts are enabled.

LOAD DATA INFILE uses concurrent inserts if the `CONCURRENT` keyword is specified and concurrent_insert is not `NEVER`. This makes the statement slower (even if no other sessions access the table) but reduces contention.

LOCK TABLES allows non-conflicting concurrent inserts if a `READ LOCAL` lock is used. Concurrent inserts are not allowed if the `LOCAL` keyword is omitted.

Notes

The decision to enable concurrent insert for a table is done when the table is opened. If you change the value of concurrent_insert, it will only affect newly opened tables. If you want it to work for also for tables in use or cached, you should do FLUSH TABLES after setting the variable.

IGNORE

The `IGNORE` option tells the server to ignore some common errors.

`IGNORE` can be used with the following statements:

- DELETE
- INSERT (see also INSERT IGNORE)
- LOAD DATA INFILE
- UPDATE
- ALTER TABLE
- CREATE TABLE … SELECT
- INSERT … SELECT

The logic used:

- Variables out of ranges are replaced with the maximum/minimum value.
- SQL_MODEs `STRICT_TRANS_TABLES`, `STRICT_ALL_TABLES`, `NO_ZERO_IN_DATE`, `NO_ZERO_DATE` are ignored.
- Inserting `NULL` in a `NOT NULL` field will insert 0 (in a numerical field), 0000-00-00 (in a date field) or an empty string (in a character field).
- Rows that cause a duplicate key error or break a foreign key constraint are not inserted, updated, or deleted.

The following errors are ignored:

Error number	Symbolic error name	Description
1022	ER_DUP_KEY	Can't write; duplicate key in table '%s'
1048	ER_BAD_NULL_ERROR	Column '%s' cannot be null
1062	ER_DUP_ENTRY	Duplicate entry '%s' for key %d
1242	ER_SUBQUERY_NO_1_ROW	Subquery returns more than 1 row
1264	ER_WARN_DATA_OUT_OF_RANGE	Out of range value for column '%s' at row %ld
1265	WARN_DATA_TRUNCATED	Data truncated for column '%s' at row %ld
1292	ER_TRUNCATED_WRONG_VALUE	Truncated incorrect %s value: '%s'
1366	ER_TRUNCATED_WRONG_VALUE_FOR_FIELD	Incorrect integer value
1369	ER_VIEW_CHECK_FAILED	CHECK OPTION failed '%s.%s'
1451	ER_ROW_IS_REFERENCED_2	Cannot delete or update a parent row
1452	ER_NO_REFERENCED_ROW_2	Cannot add or update a child row: a foreign key constraint fails (%s)
1526	ER_NO_PARTITION_FOR_GIVEN_VALUE	Table has no partition for value %s
1586	ER_DUP_ENTRY_WITH_KEY_NAME	Duplicate entry '%s' for key '%s'
1591	ER_NO_PARTITION_FOR_GIVEN_VALUE_SILENT	Table has no partition for some existing values
1748	ER_ROW_DOES_NOT_MATCH_GIVEN_PARTITION_SET	Found a row not matching the given partition set

Ignored errors normally generate a warning.

A property of the `IGNORE` clause consists in causing transactional engines and non-transactional engines (like InnoDB and Aria) to behave the same way. For example, normally a multi-row insert which tries to violate a `UNIQUE` constraint is completely rolled back on InnoDB, but might be partially executed on Aria. With the `IGNORE` clause, the statement will be partially executed in both engines.

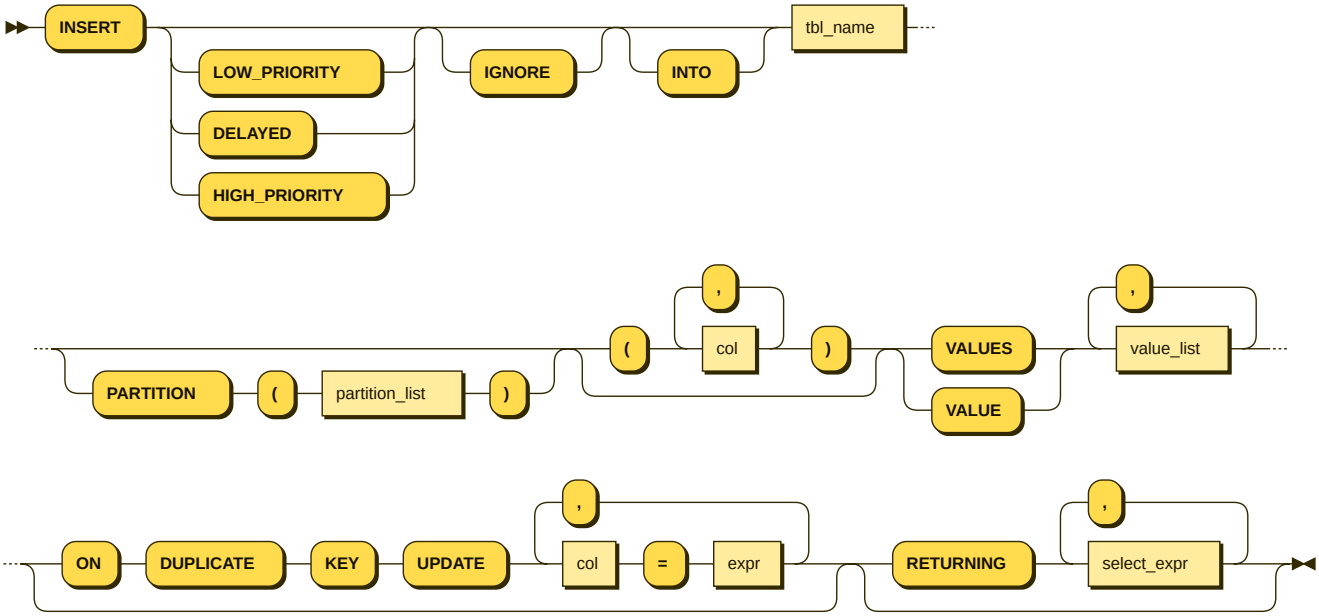
Duplicate key errors also generate warnings. The OLD_MODE server variable can be used to prevent this.

This page is licensed: CC BY-SA / Gnu FDL

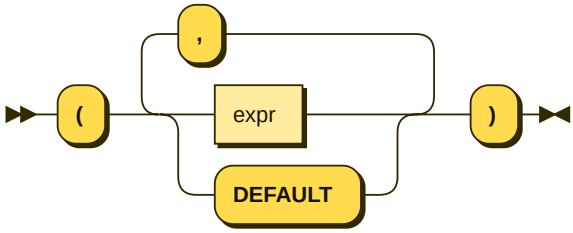
INSERT

Syntax

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
 [INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
 {VALUES | VALUE} ({expr | DEFAULT},...),(...),...
 [ ON DUPLICATE KEY UPDATE
   col=expr
     [, col=expr] ... ] [RETURNING select_expr
      [, select_expr ...]]
```



Railroad diagram of INSERT ... VALUES — equivalent to the BNF above



Railroad diagram of value_list

Or:

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name [PARTITION (partition_list)]
    SET col={expr | DEFAULT}, ...
    [ ON DUPLICATE KEY UPDATE
      col=expr
        [, col=expr] ... ] [RETURNING select_expr
      [, select_expr ...]]
```

Or:

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
    SELECT ...
    [ ON DUPLICATE KEY UPDATE
      col=expr
        [, col=expr] ... ] [RETURNING select_expr
      [, select_expr ...]]
```

The `INSERT` statement is used to insert new rows into an existing table. The `INSERT ... VALUES` and `INSERT ... SET` forms of the statement insert rows based on explicitly specified values. The `INSERT ... SELECT` form inserts rows selected from another table or tables. `INSERT ... SELECT` is discussed further in the INSERT ... SELECT article.

The table name can be specified in the form `db_name.tbl_name` or, if a default database is selected, in the form `tbl_name` (see Identifier Qualifiers). This allows to use INSERT ... SELECT to copy rows between different databases.

The PARTITION clause can be used in both the INSERT and the SELECT part. See Partition Pruning and Selection for details.

> **CURRENT**
>
> The `RETURNING` clause can be used.
>
> **< 10.5**
>
> The `RETURNING` clause is not available.

The columns list is optional. It specifies which values are explicitly inserted, and in which order. If this clause is not specified, all values must be explicitly specified, in the same order they are listed in the table definition.

The list of value follow the `VALUES` or `VALUE` keyword (which are interchangeable, regardless how much values you want to insert), and is wrapped by parenthesis. The values must be listed in the same order as the columns list. It is possible to specify more than one list to insert more than one rows with a single statement. If many rows are inserted, this is a speed optimization.

For one-row statements, the `SET` clause may be more simple, because you don't need to remember the columns order. All values are specified in the form `col = expr`.

Values can also be specified in the form of a SQL expression or subquery. A subquery in the `VALUES` list may read the same table named in the `INTO` clause — its result is computed before the insert. A subquery in a `RETURNING` clause, however, cannot read the table being inserted into.

If you use the `LOW_PRIORITY` keyword, execution of the `INSERT` is delayed until no other clients are reading from the table. If you use the `HIGH_PRIORITY` keyword, the statement has the same priority as `SELECT`s. This affects only storage engines that use only table-level locking (MyISAM, MEMORY, MERGE). However, if one of these keywords is specified, concurrent inserts cannot be used. See HIGH_PRIORITY and LOW_PRIORITY clauses for details.

INSERT DELAYED

For more details on the `DELAYED` option, see INSERT DELAYED.

HIGH PRIORITY and LOW PRIORITY

See HIGH_PRIORITY and LOW_PRIORITY.

Defaults and Duplicate Values

See INSERT - Default & Duplicate Values for details..

INSERT IGNORE

See INSERT IGNORE.

INSERT ON DUPLICATE KEY UPDATE

See INSERT ON DUPLICATE KEY UPDATE.

Examples

Specifying the column names:

```
INSERT INTO person (first_name, last_name) VALUES ('John', 'Doe');
```

Inserting more than 1 row at a time:

```
INSERT INTO tbl_name VALUES (1, "row 1"), (2, "row 2");
```

Using the `SET` clause:

```
INSERT INTO person SET first_name = 'John', last_name = 'Doe';
```

SELECTing from another table:

```
INSERT INTO contractor SELECT * FROM person WHERE status = 'c';
```

See INSERT ON DUPLICATE KEY UPDATE and INSERT IGNORE for further examples.

INSERT ... RETURNING

`INSERT ... RETURNING` returns a result set of the inserted rows.

It returns the listed columns for all the rows that are inserted, or alternatively, the specified `SELECT` expression. Any SQL expressions which can be calculated can be used in the select expression for the `RETURNING` clause, including virtual columns and aliases, expressions which use various operators such as bitwise, logical and arithmetic operators, string functions, date-time functions, numeric functions, control flow functions, secondary functions and stored functions. Along with this, statements which have subqueries and prepared statements can also be used.

Examples

Simple INSERT statement:

```
INSERT INTO t2 VALUES (1,'Dog'),(2,'Lion'),(3,'Tiger'),(4,'Leopard')
RETURNING id2,id2+id2,id2&id2,id2||id2;
+-----+---------+---------+----------+
| id2 | id2+id2 | id2&id2 | id2||id2 |
+-----+---------+---------+----------+
|   1 |       2 |       1 |        1 |
|   2 |       4 |       2 |        1 |
|   3 |       6 |       3 |        1 |
|   4 |       8 |       4 |        1 |
+-----+---------+---------+----------+
```

Using stored functions in RETURNING

```
DELIMITER |
CREATE FUNCTION f(arg INT) RETURNS INT
    BEGIN
       RETURN (SELECT arg+arg);
    END|

DELIMITER ;

PREPARE stmt FROM "INSERT INTO t1 SET id1=1, animal1='Bear' RETURNING f(id1), UPPER(animal1)";

EXECUTE stmt;
+---------+----------------+
| f(id1)  | UPPER(animal1) |
+---------+----------------+
|       2 | BEAR           |
+---------+----------------+
```

Subqueries in the `RETURNING` clause that return more than one row or column cannot be used.

Aggregate functions cannot be used in the `RETURNING` clause. Since aggregate functions work on a set of values, and if the purpose is to get the row count, `ROW_COUNT()` with `SELECT` can be used or it can be used in `INSERT...SELECT...RETURNING` if the table in the RETURNING clause is not the same as the `INSERT` table.

INSERT - Default & Duplicate Values

Default Values

If the SQL_MODE contains `STRICT_TRANS_TABLES` and you are inserting into a transactional table (like InnoDB), or if the SQL_MODE contains `STRICT_ALL_TABLES`, all `NOT NULL` columns which do not have a `DEFAULT` value (and are not AUTO_INCREMENT) must be explicitly referenced in `INSERT` statements. If not, an error like this is produced:

```
ERROR 1364 (HY000): Field 'col' doesn't have a default value
```

In all other cases, if a `NOT NULL` column without a `DEFAULT` value is not referenced, an empty value will be inserted (for example, 0 for `INTEGER` columns and '' for `CHAR` columns). See NULL Values in MariaDB:Inserting for examples.

If a `NOT NULL` column that has a `DEFAULT` value is not referenced, its declared `DEFAULT` value is inserted.

If a `NULL` column having a `DEFAULT` value is not referenced, its default value will be inserted. It is also possible to explicitly assign the default value using the `DEFAULT` keyword or the DEFAULT() function.

If the `DEFAULT` keyword is used but the column does not have a `DEFAULT` value, an error like this is produced:

```
ERROR 1364 (HY000): Field 'col' doesn't have a default value
```

Duplicate Values

By default, if you try to insert a duplicate row and there is a `UNIQUE` index, `INSERT` stops and an error like this is produced:

```
ERROR 1062 (23000): Duplicate entry 'dup_value' for key 'col'
```

To handle duplicates you can use the IGNORE clause, INSERT ON DUPLICATE KEY UPDATE or the REPLACE statement. Note that the DELAYED option is ignored when you use ON DUPLICATE KEY UPDATE.

INSERT DELAYED

Syntax

```
INSERT DELAYED ...
```

Description

The `DELAYED` option for the INSERT statement is a MariaDB/MySQL extension to standard SQL that is very useful if you have clients that cannot or need not wait for the `INSERT` to complete. This is a common situation when you use MariaDB for logging and you also periodically run `SELECT` and `UPDATE` statements that take a long time to complete.

When a client uses `INSERT DELAYED`, it gets an okay from the server at once, and the row is queued to be inserted when the table is not in use by any other thread.

Another major benefit of using `INSERT DELAYED` is that inserts from many clients are bundled together and written in one block. This is much faster than performing many separate inserts.

Note that `INSERT DELAYED` is slower than a normal `INSERT` if the table is not otherwise in use. There is also the additional overhead for the server to handle a separate thread for each table for which there are delayed rows. This means that you should use `INSERT DELAYED` only when you are really sure that you need it.

The queued rows are held only in memory until they are inserted into the table. This means that if you terminate mariadbd forcibly (for example, with kill -9) or if mariadbd dies unexpectedly, any queued rows that have not been written to disk are lost.

The number of concurrent `INSERT DELAYED` threads is limited by the max_delayed_threads server system variables. If it is set to 0, `INSERT DELAYED` is disabled. The session value can be equal to the global value, or 0 to disable this statement for the current session. If this limit has been reached, the `DELAYED` clause will be silently ignore for subsequent statements (no error will be produced).

Limitations

There are some limitations on the use of `DELAYED`:

- `INSERT DELAYED` works only with MyISAM, MEMORY, ARCHIVE, BLACKHOLE, non-transactional Aria (Aria tables are transactional by default), and OQGRAPH tables. If you execute INSERT DELAYED with another storage engine, you will get an error like this: `ERROR 1616 (HY000): DELAYED option not supported for table 'tab_name'`
- For MyISAM tables, if there are no free blocks in the middle of the data file, concurrent SELECT and INSERT statements are supported. Under these circumstances, you very seldom need to use `INSERT DELAYED` with MyISAM.
- `INSERT DELAYED` should be used only for `INSERT` statements that specify value lists. The server ignores `DELAYED` for `INSERT ... SELECT` or `INSERT ... ON DUPLICATE KEY UPDATE` statements.
- Because the `INSERT DELAYED` statement returns immediately, before the rows are inserted, you cannot use `LAST_INSERT_ID()` to get the `AUTO_INCREMENT` value that the statement might generate.
- `DELAYED` rows are not visible to `SELECT` statements until they actually have been inserted.
- After `INSERT DELAYED`, ROW_COUNT() returns the number of the rows you tried to insert, not the number of the successful writes.

- `DELAYED` is ignored on slave replication servers, so that `INSERT DELAYED` is treated as a normal `INSERT` on slaves. This is because `DELAYED` could cause the slave to have different data than the master. `INSERT DELAYED` statements are not safe for replication.
- Pending `INSERT DELAYED` statements are lost if a table is write locked and ALTER TABLE is used to modify the table structure.
- `INSERT DELAYED` is not supported for views. If you try, you will get an error like this: `ERROR 1347 (HY000): 'view_name' is not BASE TABLE`
- `INSERT DELAYED` is not supported for partitioned tables.
- `INSERT DELAYED` is not supported within stored programs.
- `INSERT DELAYED` does not work with triggers.
- `INSERT DELAYED` does not work if there is a check constraint in place.
- `INSERT DELAYED` does not work if skip-new mode is active.

- INSERT ON DUPLICATE KEY UPDATE

This page is licensed: GPLv2, originally from fill_help_tables.sql

INSERT IGNORE

Ignoring Errors

Normally INSERT stops and rolls back when it encounters an error.

By using the IGNORE keyword all errors are converted to warnings, which will not stop inserts of additional rows.

Invalid values are changed to the closest valid value and inserted, with a warning produced.

The IGNORE and DELAYED options are ignored when you use ON DUPLICATE KEY UPDATE.

> **CURRENT**
>
> Warnings are issued for duplicate key errors when using `IGNORE`. You can get the old behavior if you set OLD_MODE to `NO_DUP_KEY_WARNINGS_WITH_IGNORE`.
>
> **< 5.5.28**
>
> No warnings are issued for duplicate key errors when using `IGNORE`.

See IGNORE for a full description of effects.

Examples

```
CREATE TABLE t1 (x INT UNIQUE);

INSERT INTO t1 VALUES(1),(2);

INSERT INTO t1 VALUES(2),(3);
ERROR 1062 (23000): Duplicate entry '2' for key 'x'
SELECT * FROM t1;
+------+
| x    |
+------+
|    1 |
|    2 |
+------+

INSERT IGNORE INTO t1 VALUES(2),(3);
Query OK, 1 row affected, 1 warning (0.04 sec)

SHOW WARNINGS;
+---------+------+---------------------------------+
| Level   | Code | Message                         |
+---------+------+---------------------------------+
| Warning | 1062 | Duplicate entry '2' for key 'x' |
+---------+------+---------------------------------+

SELECT * FROM t1;
+------+
| x    |
+------+
|    1 |
|    2 |
|    3 |
+------+
```

Converting values:

```
CREATE OR REPLACE TABLE t2(id INT, t VARCHAR(2) NOT NULL, n INT NOT NULL);

INSERT INTO t2(id) VALUES (1),(2);
ERROR 1364 (HY000): Field 't' doesn't have a default value

INSERT IGNORE INTO t2(id) VALUES (1),(2);
Query OK, 2 rows affected, 2 warnings (0.026 sec)
Records: 2  Duplicates: 0  Warnings: 2

SHOW WARNINGS;
+---------+------+----------------------------------------+
| Level   | Code | Message                                |
+---------+------+----------------------------------------+
| Warning | 1364 | Field 't' doesn't have a default value |
| Warning | 1364 | Field 'n' doesn't have a default value |
+---------+------+----------------------------------------+

SELECT * FROM t2;
+------+---+---+
| id   | t | n |
+------+---+---+
|    1 |   | 0 |
|    2 |   | 0 |
+------+---+---+
```

See INSERT ON DUPLICATE KEY UPDATE for further examples using that syntax.

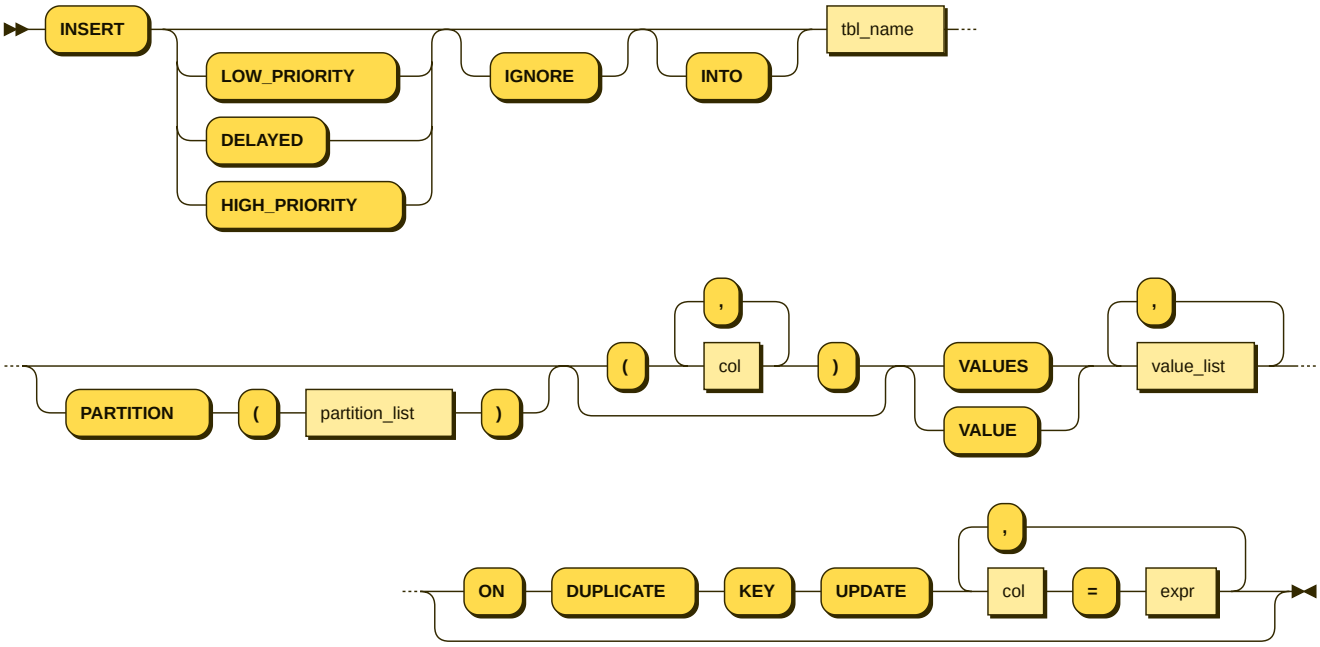
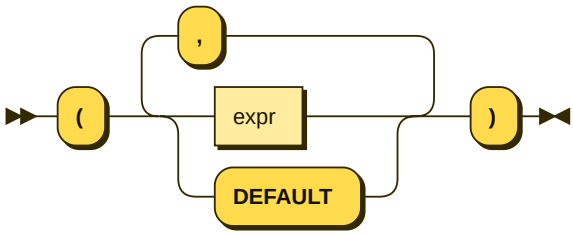
INSERT ON DUPLICATE KEY UPDATE

Syntax

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
  {VALUES | VALUE} ({expr | DEFAULT},...),(...),...
  [ ON DUPLICATE KEY UPDATE
    col=expr
      [, col=expr] ... ]
```



Railroad diagram of INSERT ... ON DUPLICATE KEY UPDATE — equivalent to the BNF above



Railroad diagram of value_list

Or:

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name [PARTITION (partition_list)]
    SET col={expr | DEFAULT}, ...
    [ ON DUPLICATE KEY UPDATE
      col=expr
        [, col=expr] ... ]
```

Or:

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
    SELECT ...
    [ ON DUPLICATE KEY UPDATE
      col=expr
        [, col=expr] ... ]
```

Description

`INSERT ... ON DUPLICATE KEY UPDATE` (often called "upsert") is a MariaDB/MySQL extension to the INSERT statement that, if it finds a duplicate unique or primary key, will instead perform an UPDATE.

The row/s affected value is reported as 1 if a row is inserted, and 2 if a row is updated, unless the API's `CLIENT_FOUND_ROWS` flag is set.

If more than one unique index is matched, only the first is updated. It is not recommended to use this statement on tables with more than one unique index.

If the table has an AUTO_INCREMENT primary key and the statement inserts a new row, the LAST_INSERT_ID() function returns the AUTO_INCREMENT value of that newly inserted row. It is not affected when the statement updates an existing row instead.

The VALUES() function can only be used in a `ON DUPLICATE KEY UPDATE` clause and has no meaning in any other context. It returns the column values from the `INSERT` portion of the statement. This function is particularly useful for multi-rows inserts.

The DELAYED option is ignored when you use `ON DUPLICATE KEY UPDATE`.

See Partition Pruning and Selection for details on the PARTITION clause.

This statement activates INSERT and UPDATE triggers. See Trigger Overview for details.

See also a similar statement, REPLACE.

Examples

```
CREATE TABLE ins_duplicate (id INT PRIMARY KEY, animal VARCHAR(30));
INSERT INTO ins_duplicate VALUES (1,'Aardvark'), (2,'Cheetah'), (3,'Zebra');
```

If there is no existing key, the statement runs as a regular INSERT:

```
INSERT INTO ins_duplicate VALUES (4,'Gorilla')
  ON DUPLICATE KEY UPDATE animal='Gorilla';
Query OK, 1 row affected (0.07 sec)
```

```
SELECT * FROM ins_duplicate;
+----+----------+
| id | animal   |
+----+----------+
|  1 | Aardvark |
|  2 | Cheetah  |
|  3 | Zebra    |
|  4 | Gorilla  |
+----+----------+
```

A regular INSERT with a primary key value of 1 will fail, due to the existing key:

```
INSERT INTO ins_duplicate VALUES (1,'Antelope');
ERROR 1062 (23000): Duplicate entry '1' for key 'PRIMARY'
```

However, we can use an INSERT ON DUPLICATE KEY UPDATE instead:

```
INSERT INTO ins_duplicate VALUES (1,'Antelope')
  ON DUPLICATE KEY UPDATE animal='Antelope';
Query OK, 2 rows affected (0.09 sec)
```

Note that there are two rows reported as affected, but this refers only to the UPDATE.

```
SELECT * FROM ins_duplicate;
+----+----------+
| id | animal   |
+----+----------+
|  1 | Antelope |
|  2 | Cheetah  |
|  3 | Zebra    |
|  4 | Gorilla  |
+----+----------+
```

Adding a second unique column:

```
ALTER TABLE ins_duplicate ADD id2 INT;
UPDATE ins_duplicate SET id2=id+10;
ALTER TABLE ins_duplicate ADD UNIQUE KEY(id2);
```

Where two rows match the unique keys match, only the first is updated. This can be unsafe and is not recommended unless you are certain what you are doing.

```
INSERT INTO ins_duplicate VALUES (2,'Lion',13)
  ON DUPLICATE KEY UPDATE animal='Lion';
Query OK, 2 rows affected (0.004 sec)

SELECT * FROM ins_duplicate;
+----+----------+------+
| id | animal   | id2  |
+----+----------+------+
|  1 | Antelope |   11 |
|  2 | Lion     |   12 |
|  3 | Zebra    |   13 |
|  4 | Gorilla  |   14 |
+----+----------+------+
```

Although the third row with an id of 3 has an id2 of 13, which also matched, it was not updated.

Changing id to an auto_increment field. If a new row is added, the auto_increment is moved forward. If the row is updated, it remains the same.

```
ALTER TABLE `ins_duplicate` CHANGE `id` `id` INT( 11 ) NOT NULL AUTO_INCREMENT;
ALTER TABLE ins_duplicate DROP id2;
SELECT Auto_increment FROM INFORMATION_SCHEMA.TABLES
  WHERE TABLE_NAME='ins_duplicate';
+----------------+
| Auto_increment |
+----------------+
|              5 |
+----------------+

INSERT INTO ins_duplicate VALUES (2,'Leopard')
  ON DUPLICATE KEY UPDATE animal='Leopard';
Query OK, 2 rows affected (0.00 sec)

SELECT Auto_increment FROM INFORMATION_SCHEMA.TABLES
  WHERE TABLE_NAME='ins_duplicate';
+----------------+
| Auto_increment |
+----------------+
|              5 |
+----------------+

INSERT INTO ins_duplicate VALUES (5,'Wild Dog')
  ON DUPLICATE KEY UPDATE animal='Wild Dog';
Query OK, 1 row affected (0.09 sec)

SELECT * FROM ins_duplicate;
+----+----------+
| id | animal   |
+----+----------+
|  1 | Antelope |
|  2 | Leopard  |
|  3 | Zebra    |
|  4 | Gorilla  |
|  5 | Wild Dog |
+----+----------+

SELECT Auto_increment FROM INFORMATION_SCHEMA.TABLES
  WHERE TABLE_NAME='ins_duplicate';
+----------------+
| Auto_increment |
+----------------+
|              6 |
+----------------+
```

Referring to column values from the INSERT portion of the statement:

```
INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
    ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

See the VALUES() function for more.

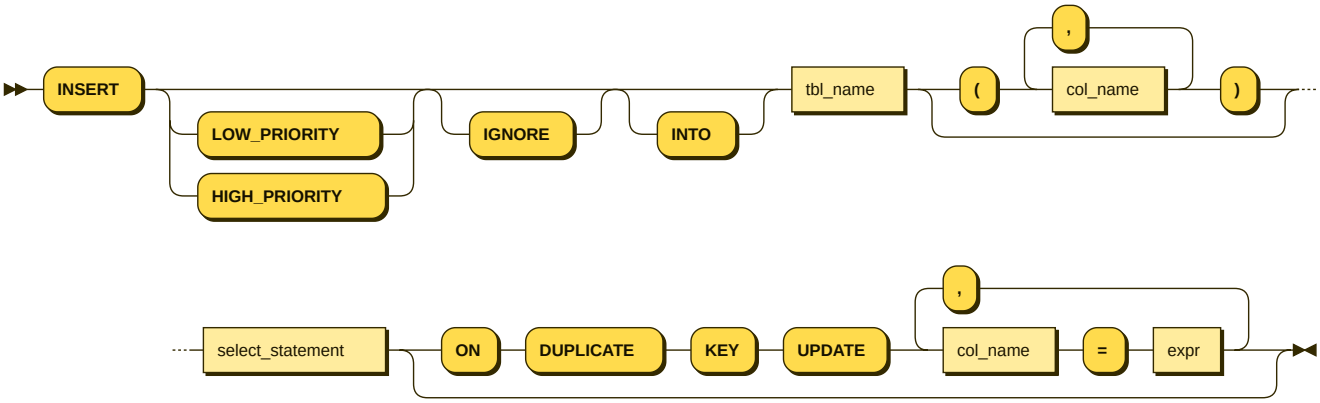
INSERT SELECT

Syntax

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name [(col_name,...)]
    SELECT ...
    [ ON DUPLICATE KEY UPDATE col_name=expr, ... ]
```



Railroad diagram of INSERT ... SELECT — equivalent to the BNF above

Description

With `INSERT ... SELECT`, you can quickly insert many rows into a table from one or more other tables. For example:

```
INSERT INTO tbl_temp2 (fld_id)
  SELECT tbl_temp1.fld_order_id
  FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

`tbl_name` can also be specified in the form `db_name.tbl_name` (see Identifier Qualifiers). This allows to copy rows between different databases.

If the new table has a primary key or UNIQUE indexes, you can use IGNORE to handle duplicate key errors during the query. The newer values will not be inserted if an identical value already exists.

REPLACE can be used instead of `INSERT` to prevent duplicates on `UNIQUE` indexes by deleting old values. In that case, `ON DUPLICATE KEY UPDATE` cannot be used.

`INSERT ... SELECT` works for tables which already exist. To create a table for a given resultset, you can use CREATE TABLE ... SELECT.

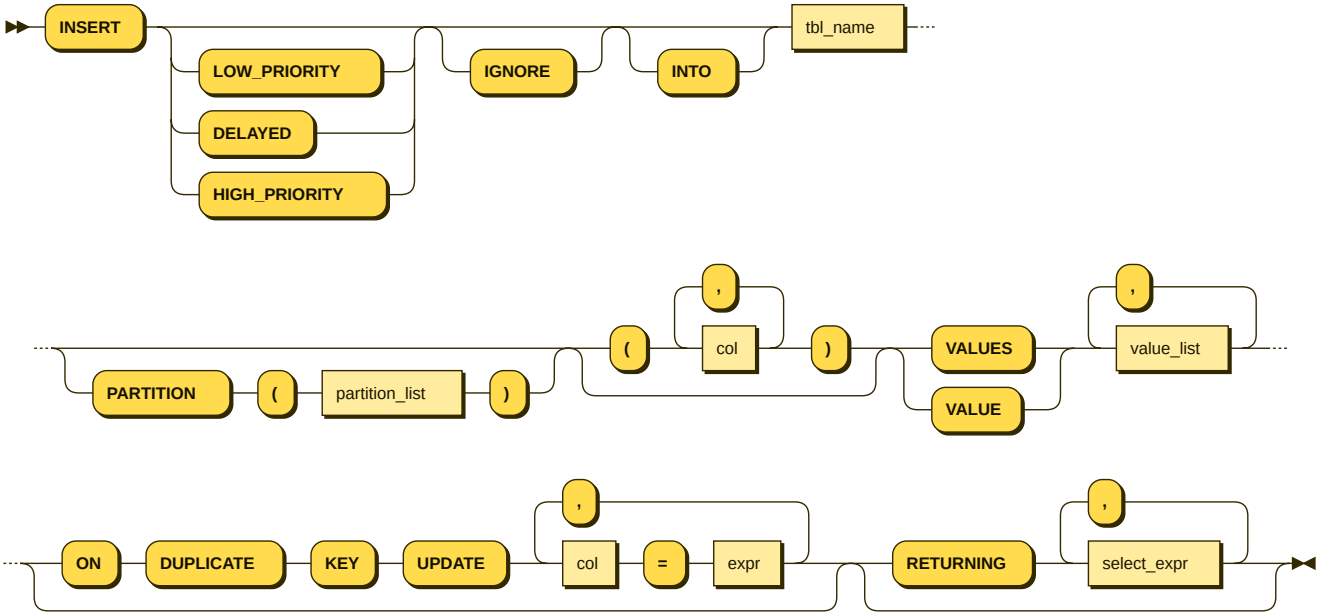
INSERT…RETURNING

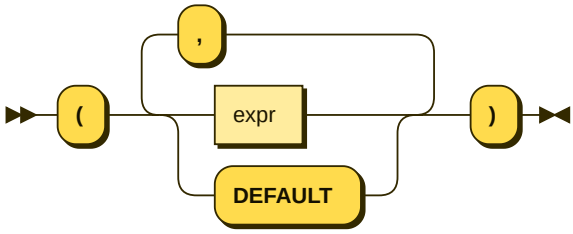
> **Note:**
>
> INSERT … RETURNING was added in MariaDB 10.5.0, and returns a result set of the inserted rows.

Syntax

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
 [INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
 {VALUES | VALUE} ({expr | DEFAULT},...),(...),...
 [ ON DUPLICATE KEY UPDATE
   col=expr
     [, col=expr] ... ] [RETURNING select_expr
      [, select_expr ...]]
```



Railroad diagram of INSERT (with RETURNING and ON DUPLICATE KEY UPDATE branches) — equivalent to the BNF above



Railroad diagram of value_list

Or:

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name [PARTITION (partition_list)]
    SET col={expr | DEFAULT}, ...
    [ ON DUPLICATE KEY UPDATE
      col=expr
        [, col=expr] ... ] [RETURNING select_expr
      [, select_expr ...]]
```

Or:

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
    SELECT ...
    [ ON DUPLICATE KEY UPDATE
      col=expr
        [, col=expr] ... ] [RETURNING select_expr
      [, select_expr ...]]
```

Description

`INSERT ... RETURNING` returns a resultset of the inserted rows.

It returns the listed columns for all the rows that are inserted, or alternatively, the specified `SELECT` expression. Any SQL expressions which can be calculated can be used in the select expression for the `RETURNING` clause, including virtual columns and aliases, expressions which use various operators such as bitwise, logical and arithmetic operators, string functions, date-time functions, numeric functions, control flow functions, secondary functions and stored functions. Along with this, statements which have subqueries and prepared statements can also be used.

Examples

Simple INSERT statements:

```
CREATE OR REPLACE TABLE t2 (id INT, animal VARCHAR(20), t TIMESTAMP);

INSERT INTO t2 (id) VALUES (2),(3) RETURNING id,t;
+------+---------------------+
| id   | t                   |
+------+---------------------+
|    2 | 2021-04-28 00:59:32 |
|    3 | 2021-04-28 00:59:32 |
+------+---------------------+
```

```
INSERT INTO t2(id,animal) VALUES (1,'Dog'),(2,'Lion'),(3,'Tiger'),(4,'Leopard')
  RETURNING id,id+id,id&id,id||id;
+------+-------+-------+--------+
| id   | id+id | id&id | id||id |
+------+-------+-------+--------+
|    1 |     2 |     1 |      1 |
|    2 |     4 |     2 |      1 |
|    3 |     6 |     3 |      1 |
|    4 |     8 |     4 |      1 |
+------+-------+-------+--------+
```

Using stored functions in `RETURNING`:

```
DELIMITER |
CREATE FUNCTION f(arg INT) RETURNS INT
    BEGIN
       RETURN (SELECT arg+arg);
    END|

DELIMITER ;

PREPARE stmt FROM "INSERT INTO t1 SET id1=1, animal1='Bear' RETURNING f(id1), UPPER(animal1)";

EXECUTE stmt;
+---------+----------------+
| f(id1)  | UPPER(animal1) |
+---------+----------------+
|       2 | BEAR           |
+---------+----------------+
```

Subqueries in the `RETURNING` clause that return more than one row or column cannot be used.

Aggregate functions cannot be used in the `RETURNING` clause. Since aggregate functions work on a set of values, and if the purpose is to get the row count, `ROW_COUNT()` with `SELECT` can be used or it can be used in `INSERT...SELECT...RETURNING` if the table in the `RETURNING` clause is not the same as the `INSERT` table.

LOAD Data into Tables or Index

See LOAD DATA INFILE.

Import rows into a table at high speed from a text file, with control over field and line formatting, column mapping, and duplicate handling.

See LOAD INDEX.

Preload table indexes into the key cache. This command, used for MyISAM tables, loads index blocks into memory to warm up the cache and improve subsequent query performance.

See LOAD XML.

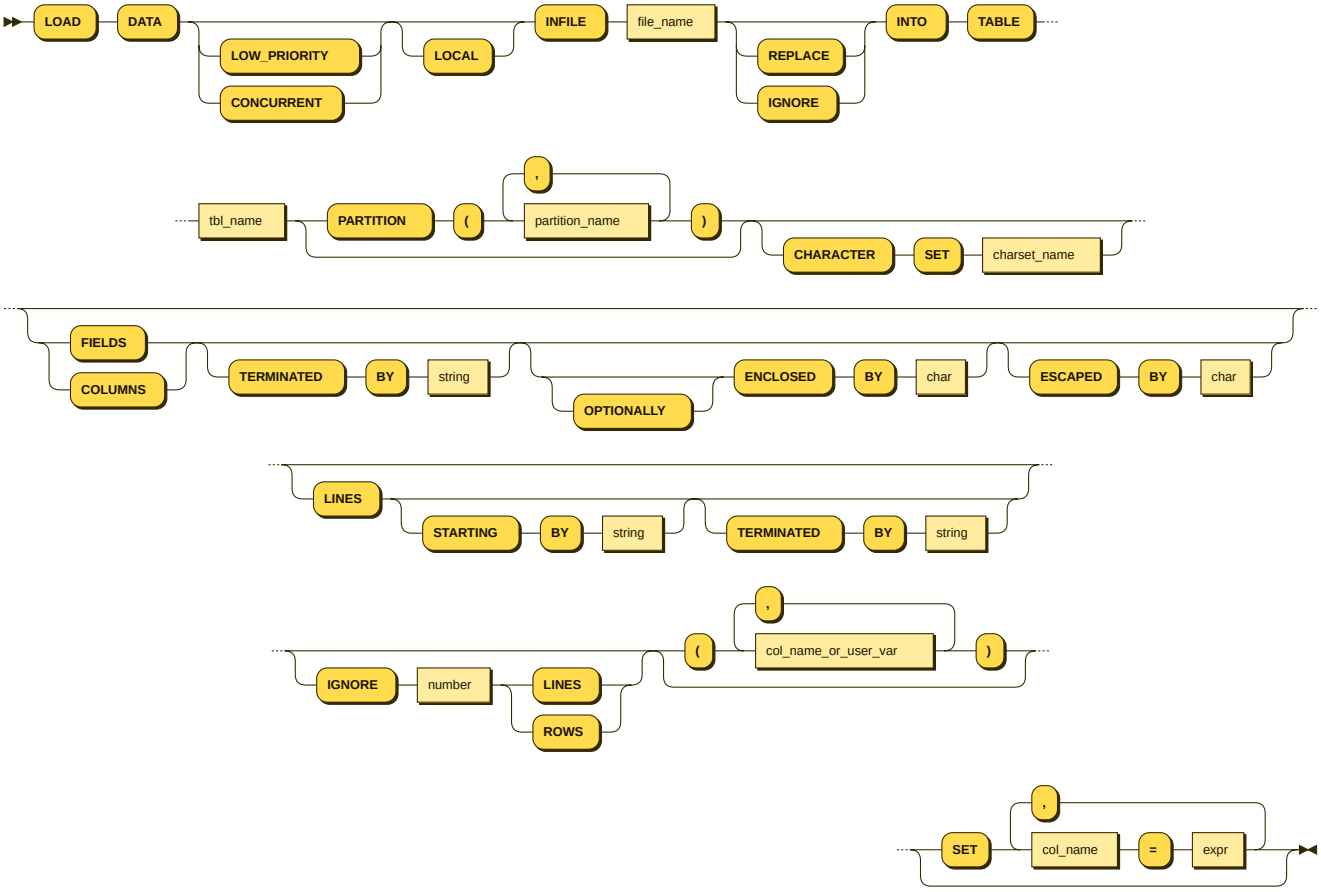
Read data from an XML file into a table. This command parses XML content, mapping elements and attributes to table columns for direct data import.

This page is licensed: CC BY-SA / Gnu FDL

LOAD DATA INFILE

Syntax

```
LOAD DATA [LOW_PRIORITY | CONCURRENT] [LOCAL] INFILE 'file_name'
    [REPLACE | IGNORE]
    INTO TABLE tbl_name
    [PARTITION (partition_name, ...)]
    [CHARACTER SET charset_name]
    [{FIELDS | COLUMNS}
        [TERMINATED BY 'string']
        [[OPTIONALLY] ENCLOSED BY 'CHAR']
        [ESCAPED BY 'CHAR']
    ]
    [LINES
        [STARTING BY 'string']
        [TERMINATED BY 'string']
    ]
    [IGNORE number {LINES|ROWS}]
    [(col_name_or_user_var,...)]
    [SET col_name = expr,...]
```



Railroad diagram of LOAD DATA INFILE — equivalent to the BNF above

Description

`LOAD DATA INFILE` is unsafe for statement-based replication.

Reads rows from a text file into the designated table on the database at a very high speed. The file name must be given as a literal string.

Files are written to disk using the SELECT INTO OUTFILE statement. You can then read the files back into a table using the `LOAD DATA INFILE` statement. The `FIELDS` and `LINES` clauses are the same in both statements and by default fields are expected to be terminated with tabs () and lines with newlines (). These clauses are optional, but if both are specified then the `FIELDS` clause must precede `LINES`.

Executing this statement activates `INSERT` triggers.

One must have the FILE privilege to be able to execute LOAD DATA INFILE. This is to ensure normal users cannot read system files. LOAD DATA LOCAL INFILE does not have this requirement.

If the secure_file_priv system variable is set (by default it is not), the loaded file must be present in the specified directory.

Note that MariaDB's systemd unit file restricts access to `/home`, `/root`, and `/run/user` by default. See Configuring access to home directories.

LOAD DATA LOCAL INFILE

When you execute the `LOAD DATA INFILE` statement, MariaDB Server attempts to read the input file from its own file system. By contrast, when you execute the `LOAD DATA LOCAL INFILE` statement, the client attempts to read the input file from its file system, and it sends the contents of the input file to the MariaDB Server. This allows you to load files from the client's local file system into the database.

If you don't want to permit this operation (perhaps for security reasons), you can disable the `LOAD DATA LOCAL INFILE` statement on either the server or the client.

- The `LOAD DATA LOCAL INFILE` statement can be disabled on the server by setting the local_infile system variable to `0`.
- The `LOAD DATA LOCAL INFILE` statement can be disabled on the client. If you are using MariaDB Connector/C, this can be done by unsetting the `CLIENT_LOCAL_FILES` capability flag with the mysql_real_connect function or by unsetting the `MYSQL_OPT_LOCAL_INFILE` option with mysql_optionsv function. If you are using a different client or client library, then see the documentation for your specific client or client library to determine how it handles the `LOAD DATA LOCAL INFILE` statement.
- The `LOAD DATA LOCAL INFILE` strict modes like `STRICT_TRANS_TABLES` are disabled with keyword "local". (MDEV-11235)

If the `LOAD DATA LOCAL INFILE` statement is disabled by either the server or the client and if the user attempts to execute it, then the server will cause the statement to fail with the following error message:

```
The used command is not allowed with this MariaDB version
```

Note that it is not entirely accurate to say that the MariaDB version does not support the command. It would be more accurate to say that the MariaDB configuration does not support the command. See MDEV-20500 for more information.

From MariaDB 10.5.2, the error message is more accurate:

```
The used command is not allowed because the MariaDB server or client
  has disabled the local infile capability
```

REPLACE and IGNORE

If you load data from a file into a table that already contains data and has a primary key, you may encounter issues where the statement attempts to insert a row with a primary key that already exists. When this happens, the statement fails with Error 1062, protecting the data already on the table. If you want MariaDB to overwrite duplicates, use the `REPLACE` keyword.

The `REPLACE` keyword works like the REPLACE statement. Here, the statement attempts to load the data from the file. If the row does not exist, it adds it to the table. If the row contains an existing primary key, it replaces the table data. That is, in the event of a conflict, it assumes the file contains the desired row.

This operation can cause a degradation in load speed by a factor of 20 or more if the part that has already been loaded is larger than the capacity of the InnoDB Buffer Pool. This happens because it causes a lot of turnaround in the buffer pool.

Use the `IGNORE` keyword when you want to skip any rows that contain a conflicting primary key. Here, the statement attempts to load the data from the file. If the row does not exist, it adds it to the table. If the row contains an existing primary key, it ignores the addition request and moves on to the next. That is, in the event of a conflict, it assumes the table contains the desired row.

`IGNORE number {LINES|ROWS}`

The `IGNORE number LINES` syntax can be used to ignore a number of rows from the beginning of the file. Most often this is needed when the file starts with one row that includes the column headings.

Character Sets

When the statement opens the file, it attempts to read the contents using the default character-set, as defined by the character_set_database system variable.

In the cases where the file was written using a character-set other than the default, you can specify the character-set to use with the `CHARACTER SET` clause in the statement. It ignores character-sets specified by the SET NAMES statement and by the character_set_client system variable. Setting the `CHARACTER SET` clause to a value of `binary` indicates "no conversion."

The statement interprets all fields in the file as having the same character-set, regardless of the column data type. To properly interpret file contents, you must ensure that it was written with the correct character-set. If you write a data file with mariadb-dump -T or with the SELECT INTO OUTFILE statement with the mariadb client, be sure to use the `--default-character-set` option, so that the output is written with the desired character-set.

When using mixed character sets, use the `CHARACTER SET` clause in both SELECT INTO OUTFILE and `LOAD DATA INFILE` to ensure that MariaDB correctly interprets the escape sequences.

The character_set_filesystem system variable controls the interpretation of the filename.
It is currently not possible to load data files that use the `ucs2` character set.

Preprocessing Inputs

col_name_or_user_var can be a column name, or a user variable. In the case of a variable, the SET statement can be used to preprocess the value before loading into the table.

Priority and Concurrency

In storage engines that perform table-level locking (MyISAM, MEMORY and MERGE), using the LOW_PRIORITY keyword, MariaDB delays insertions until no other clients are reading from the table. Alternatively, when using the MyISAM storage engine, you can use the CONCURRENT keyword to perform concurrent insertion.

The `LOW_PRIORITY` and `CONCURRENT` keywords are mutually exclusive. They cannot be used in the same statement.

Progress Reporting

The `LOAD DATA INFILE` statement supports progress reporting. You may find this useful when dealing with long-running operations. Using another client you can issue a SHOW PROCESSLIST query to check the progress of the data load.

Using mariadb-import

> **CURRENT**
>
> MariaDB ships with a separate utility for loading data from files: mariadb-import. It operates by sending `LOAD DATA INFILE` statements to the server.
>
> **< 10.5**
>
> MariaDB ships with a separate utility for loading data from files: `mysqlimport` . It operates by sending `LOAD DATA INFILE` statements to the server.

Using mariadb-import you can compress the file using the `--compress` option, to get better performance over slow networks, providing both the client and server support the compressed protocol. Use the `--local` option to load from the local file system.

Indexing

In cases where the storage engine supports ALTER TABLE… DISABLE KEYS statements (MyISAM and Aria), the `LOAD DATA INFILE` statement automatically disables indexes during the execution.

Examples

You have a file with this content (note the separator is ‘,’, not tab, which is the default):

```
2,2
3,3
4,4
5,5
6,8
```

```
CREATE TABLE t1 (a INT, b INT, c INT, PRIMARY KEY (a));
LOAD DATA LOCAL INFILE
 '/tmp/loaddata7.dat' INTO TABLE t1 FIELDS TERMINATED BY ',' (a,b) SET c=a+b;
SELECT * FROM t1;
+------+------+------+
| a    | b    | c    |
+------+------+------+
|    2 |    2 |    4 |
|    3 |    3 |    6 |
|    4 |    4 |    8 |
|    5 |    5 |   10 |
|    6 |    8 |   14 |
+------+------+------+
```

Another example, given the following data (the separator is a tab):

```
1	a
2	b
```

The value of the first column is doubled before loading:

```
LOAD DATA INFILE 'ld.txt' INTO TABLE ld (@i,v) SET i=@i*2;

SELECT * FROM ld;
+------+------+
| i    | v    |
+------+------+
|    2 | a    |
|    4 | b    |
+------+------+
```

LOAD INDEX

Syntax

```
LOAD INDEX INTO CACHE
  tbl_index_list [, tbl_index_list] ...

tbl_index_list:
  tbl_name
    [[INDEX|KEY] (index_name[, index_name] ...)]
    [IGNORE LEAVES]
```

Description

The `LOAD INDEX INTO CACHE` statement preloads a table index into the key cache to which it has been assigned by an explicit CACHE INDEX statement, or into the default key cache otherwise. `LOAD INDEX INTO CACHE` is used only for MyISAM or Aria tables.

The `IGNORE LEAVES` modifier causes only blocks for the nonleaf nodes of the index to be preloaded.

This page is licensed: GPLv2, originally from fill_help_tables.sql

LOAD XML

Syntax

```
LOAD XML [LOW_PRIORITY | CONCURRENT] [LOCAL] INFILE 'file_name'
    [REPLACE | IGNORE]
    INTO TABLE [db_name.]tbl_name
    [CHARACTER SET charset_name]
    [ROWS IDENTIFIED BY '<tagname>']
    [IGNORE number {LINES | ROWS}]
    [(column_or_user_var,...)]
    [SET col_name = expr,...]
```

Description

The LOAD XML statement reads data from an XML file into a table. The `file_name` must be given as a literal string. The `tagname` in the optional `ROWS IDENTIFIED BY` clause must also be given as a literal string, and must be surrounded by angle brackets (< and >).

LOAD XML acts as the complement of running the mariadb client in XML output mode (that is, starting the client with the –xml option). To write data from a table to an XML file, use a command such as the following one from the system shell:

```
shell> mariadb --xml -e 'SELECT * FROM mytable' > file.xml
```

To read the file back into a table, use LOAD XML INFILE. By default, the element is considered to be the equivalent of a database table row; this can be changed using the ROWS IDENTIFIED BY clause.

This statement supports three different XML formats:

- Column names as attributes and column values as attribute values:

```
<row column1="value1" column2="value2" .../>
```

- Column names as tags and column values as the content of these tags:

```
<row>
  <column1>value1</column1>
  <column2>value2</column2>
</row>
```

- Column names are the name attributes of tags, and values are the contents of these tags:

```
<row>
  <field name='column1'>value1</field>
  <field name='column2'>value2</field>
</row>
```

This is the format used by other tools, such as mariadb-dump.

All 3 formats can be used in the same XML file; the import routine automatically detects the format for each row and interprets it correctly. Tags are matched based on the tag or attribute name and the column name.

The following clauses work essentially the same way for LOAD XML as they do for LOAD DATA:

- `LOW_PRIORITY` or `CONCURRENT`
- `LOCAL`
- `REPLACE` or `IGNORE`
- `CHARACTER SET`
- (column_or_user_var,…)
- `SET`

See LOAD DATA for more information about these clauses.

The `IGNORE` number `LINES` or `IGNORE` number `ROWS` clause causes the first number rows in the XML file to be skipped. It is analogous to the `LOAD DATA` statement's `IGNORE ... LINES` clause.

If the LOW_PRIORITY keyword is used, insertions are delayed until no other clients are reading from the table. The `CONCURRENT` keyword allows the use of concurrent inserts. These clauses cannot be specified together.

This statement activates `INSERT` triggers.

DUAL

Description

You can use `DUAL` instead of a table name in situations where no tables are referenced, such as the following SELECT statement:

```
SELECT 1 + 1 FROM DUAL;
+-------+
| 1 + 1 |
+-------+
|     2 |
+-------+
```

`DUAL` is purely for the convenience of people who require that all `SELECT` statements should have `FROM` and possibly other clauses. MariaDB ignores the clauses. MariaDB does not require `FROM DUAL` if no tables are referenced.

FROM DUAL could be used when you only SELECT computed values, but require a `WHERE` clause, perhaps to test that a script correctly handles empty resultsets:

```
SELECT 1 FROM DUAL WHERE FALSE;
Empty set (0.00 sec)
```

See Also

- SELECT

This page is licensed: GPLv2, originally from fill_help_tables.sql

FOR UPDATE

InnoDB supports row-level locking. Selected rows can be locked using LOCK IN SHARE MODE or FOR UPDATE. In both cases, a lock is acquired on the rows read by the query, and it will be released when the current transaction is committed.

The `FOR UPDATE` clause of SELECT applies only when autocommit is set to 0 or the `SELECT` is enclosed in a transaction. A lock is acquired on the rows, and other transactions are prevented from writing the rows, acquire locks, and from reading them (unless their isolation level is READ UNCOMMITTED).

If `autocommit` is set to 1, the LOCK IN SHARE MODE and `FOR UPDATE` clauses have no effect in InnoDB. For non-transactional storage engines like MyISAM and ARIA, a table level lock will be taken even if autocommit is set to 1.

If the isolation level is set to SERIALIZABLE, all plain `SELECT` statements are converted to `SELECT ... LOCK IN SHARE MODE`, provided `AUTOCOMMIT` is disabled (or the statement runs inside an explicit transaction). With `AUTOCOMMIT` enabled, plain `SELECT` statements run as consistent reads.

Example

```
SELECT * FROM trans WHERE period=2001 FOR UPDATE;
```

GROUP BY

Use the `GROUP BY` clause in a SELECT statement to group rows together that have the same value in one or more column, or the same computed value using expressions with any functions and operators except grouping functions. When you use a `GROUP BY` clause, you will get a single result row for each group of rows that have the same value for the expression given in `GROUP BY`.

When grouping rows, grouping values are compared as if by the = operator. For string values, the `=` operator ignores trailing whitespace and may normalize characters and ignore case, depending on the collation in use.

You can use any of the grouping functions in your select expression. Their values will be calculated based on all the rows that have been grouped together for each result row. If you select a non-grouped column or a value computed from a non-grouped column, it is undefined which row the returned value is taken from. This is not permitted if the `ONLY_FULL_GROUP_BY` SQL_MODE is used.

You can use multiple expressions in the `GROUP BY` clause, separated by commas.
Rows are grouped together if they match on each of the expressions.

You can also use a single integer as the grouping expression. If you use an integer *n*, the results will be grouped by the _n_th column in the select expression.

The `WHERE` clause is applied before the `GROUP BY` clause. It filters non-aggregated rows before the rows are grouped together. To filter grouped rows based on aggregate values, use the `HAVING` clause. The `HAVING` clause takes any expression and evaluates it as a boolean, just like the `WHERE` clause. You can use grouping functions in the `HAVING` clause. As with the select expression, if you reference non-grouped columns in the `HAVING` clause, the behavior is undefined.

By default, if a `GROUP BY` clause is present, the rows in the output will be sorted by the expressions used in the `GROUP BY`. You can also specify `ASC` or `DESC` (ascending, descending) after those expressions, like in ORDER BY. The default is `ASC`.

If you want the rows to be sorted by another field, you can add an explicit ORDER BY. If you don't want the result to be ordered, you can add ORDER BY NULL.

WITH ROLLUP

The `WITH ROLLUP` modifier adds extra rows to the result set that represent super-aggregate summaries. For a full description with examples, see SELECT WITH ROLLUP.

GROUP BY Examples

Consider the following table that records how many times each user has played and won a game:

```
CREATE TABLE plays (name VARCHAR(16), plays INT, wins INT);
INSERT INTO plays VALUES
  ("John", 20, 5),
  ("Robert", 22, 8),
  ("Wanda", 32, 8),
  ("Susan", 17, 3);
```

Get a list of win counts along with a count:

```
SELECT wins, COUNT(*) FROM plays GROUP BY wins;
+------+----------+
| wins | COUNT(*) |
+------+----------+
|    3 |        1 |
|    5 |        1 |
|    8 |        2 |
+------+----------+
3 rows in set (0.00 sec)
```

The `GROUP BY` expression can be a computed value, and can refer back to an identifier specified with `AS`. Get a list of win averages along with a count:

```
SELECT (wins / plays) AS winavg, COUNT(*) FROM plays GROUP BY winavg;
+--------+----------+
| winavg | COUNT(*) |
+--------+----------+
| 0.1765 |        1 |
| 0.2500 |        2 |
| 0.3636 |        1 |
+--------+----------+
3 rows in set (0.00 sec)
```

You can use any grouping function in the select expression. For each win average as above, get a list of the average play count taken to get that average:

```
SELECT (wins / plays) AS winavg, AVG(plays) FROM plays
  GROUP BY winavg;
+--------+------------+
| winavg | AVG(plays) |
+--------+------------+
| 0.1765 |    17.0000 |
| 0.2500 |    26.0000 |
| 0.3636 |    22.0000 |
+--------+------------+
3 rows in set (0.00 sec)
```

You can filter on aggregate information using the `HAVING` clause. The `HAVING` clause is applied after `GROUP BY` and allows you to filter on aggregate data that is not available to the `WHERE` clause. Restrict the above example to results that involve an average number of plays over 20:

```
SELECT (wins / plays) AS winavg, AVG(plays) FROM plays
  GROUP BY winavg HAVING AVG(plays) > 20;
+--------+------------+
| winavg | AVG(plays) |
+--------+------------+
| 0.2500 |    26.0000 |
| 0.3636 |    22.0000 |
+--------+------------+

LIMIT

Description

Use the `LIMIT` clause to restrict the number of returned rows. When you use a single integer *n* with `LIMIT`, the first *n* rows will be returned. Use the ORDER BY clause to control which rows come first. You can also select a number of rows after an offset using either of the following:

```
LIMIT offset, row_count
LIMIT row_count OFFSET offset
```

When you provide an offset *m* with a limit *n*, the first *m* rows will be ignored, and the following *n* rows will be returned.

Executing an UPDATE with the `LIMIT` clause is not safe for replication. `LIMIT 0` is an exception to this rule.

There is a LIMIT ROWS EXAMINED optimization which provides the means to terminate the execution of SELECT statements which examine too many rows, and thus use too many resources. See LIMIT ROWS EXAMINED.

Multi-Table Updates

It is possible to use `LIMIT` (or ORDER BY) in a multi-table UPDATE statement.

GROUP_CONCAT

> **CURRENT**
>
> It is possible to use `LIMIT` with GROUP_CONCAT().
>
> **< 10.3.3**
>
> It is **not** possible to use `LIMIT` with GROUP_CONCAT().

Examples

```
CREATE TABLE members (name VARCHAR(20));
INSERT INTO members VALUES('Jagdish'),('Kenny'),('Rokurou'),('Immaculada');

SELECT * FROM members;
+------------+
| name       |
+------------+
| Jagdish    |
| Kenny      |
| Rokurou    |
| Immaculada |
+------------+
```

Select the first two names (no ordering specified):

```
SELECT * FROM members LIMIT 2;
+---------+
| name    |
+---------+
| Jagdish |
| Kenny   |
+---------+
```

All the names in alphabetical order:

```
SELECT * FROM members ORDER BY name;
+------------+
| name       |
+------------+
| Immaculada |
| Jagdish    |
| Kenny      |
| Rokurou    |
+------------+
```

The first two names, ordered alphabetically:

```
SELECT * FROM members ORDER BY name LIMIT 2;
+------------+
| name       |
+------------+
| Immaculada |
| Jagdish    |
+------------+
```

The third name, ordered alphabetically (the first name would be offset zero, so the third is offset two):

```
SELECT * FROM members ORDER BY name LIMIT 2,1;
+-------+
| name  |
+-------+
| Kenny |
+-------+
```

`LIMIT` can be used in a multi-table update:

```
CREATE TABLE warehouse (product_id INT, qty INT);
INSERT INTO warehouse VALUES (1,100),(2,100),(3,100),(4,100);

CREATE TABLE store (product_id INT, qty INT);
INSERT INTO store VALUES (1,5),(2,5),(3,5),(4,5);

UPDATE warehouse,store SET warehouse.qty = warehouse.qty-2, store.qty = store.qty+2
  WHERE (warehouse.product_id = store.product_id AND store.product_id  >= 1)
    ORDER BY store.product_id DESC LIMIT 2;

SELECT * FROM warehouse;
+------------+------+
| product_id | qty  |
+------------+------+
|          1 |  100 |
|          2 |  100 |
|          3 |   98 |
|          4 |   98 |
+------------+------+

SELECT * FROM store;
+------------+------+
| product_id | qty  |
+------------+------+
|          1 |    5 |
|          2 |    5 |
|          3 |    7 |
|          4 |    7 |
+------------+------+
```

When using `LIMIT` with GROUP_CONCAT, you can simplify certain queries. Consider this table:

```
CREATE TABLE d (dd DATE, cc INT);

INSERT INTO d VALUES ('2017-01-01',1);
INSERT INTO d VALUES ('2017-01-02',2);
INSERT INTO d VALUES ('2017-01-04',3);
```

The following query works fine, but is rather complex:

```
SELECT SUBSTRING_INDEX(GROUP_CONCAT(CONCAT_WS(":",dd,cc)
ORDER BY cc DESC),",",1) FROM d;
+-----------------------------------------------------------------------------+
| SUBSTRING_INDEX(GROUP_CONCAT(CONCAT_WS(":",dd,cc) ORDER BY cc DESC),",",1) |
+-----------------------------------------------------------------------------+
| 2017-01-04:3                                                                |
+-----------------------------------------------------------------------------+
```

It can be simplified to this:

```
SELECT GROUP_CONCAT(CONCAT_WS(":",dd,cc)
ORDER BY cc DESC LIMIT 1) FROM d;
+-------------------------------------------------------------+
| GROUP_CONCAT(CONCAT_WS(":",dd,cc) ORDER BY cc DESC LIMIT 1) |
+-------------------------------------------------------------+
| 2017-01-04:3                                                |
+-------------------------------------------------------------+
```

LOCK IN SHARE MODE

InnoDB supports row-level locking. Selected rows can be locked using `LOCK IN SHARE MODE` or FOR UPDATE. In both cases, a lock is acquired on the rows read by the query, and it will be released when the current transaction is committed.

When `LOCK IN SHARE MODE` is specified in a SELECT statement, MariaDB will wait until all transactions that have modified the rows are committed. Then, a read lock is acquired. All transactions can read the rows, but if they want to modify them, they have to wait until your transaction is committed.

InnoDB locks index records rather than logical rows. If a `SELECT` is satisfied by a secondary index (a covering index read), it just locks that index. Instead, the primary key records will be locked if a concurrent `UPDATE` modifies columns outside of that index. These locks do not overlap under `READ COMMITTED` isolation level, so the update can proceed. To ensure a block is used, the `SELECT` query must reference columns from the primary index.

For further information and an example, see InnoDB Lock Modes.

If autocommit is set to 1 (the default), the LOCK IN SHARE MODE and FOR UPDATE clauses have no effect in InnoDB. For non-transactional storage engines like MyISAM and ARIA, a table level lock will be taken even if autocommit is set to 1.

ORDER BY

Description

Use the `ORDER BY` clause to order a resultset, such as that are returned from a SELECT statement. You can specify just a column or use any expression with functions. If you are using the `GROUP BY` clause, you can use grouping functions in `ORDER BY`. Ordering is done after grouping.

You can use multiple ordering expressions, separated by commas. Rows are sorted by the first expression, then by the second expression if they have the same value for the first, and so on.

You can use the keywords `ASC` and `DESC` after each ordering expression to force that ordering to be ascending or descending, respectively. Ordering is ascending by default.

You can also use a single integer as the ordering expression. If you use an integer *n*, the results is ordered by the n^{th} column in the select expression.

When string values are compared, they are compared as if by the STRCMP function. `STRCMP` ignores trailing whitespace and may normalize characters and ignore case, depending on the collation in use.

Duplicated entries in the `ORDER BY` clause are removed.

`ORDER BY` can also be used to order the activities of a DELETE or UPDATE statement (usually with the LIMIT clause).

> **CURRENT**
>
> It is possible to use `ORDER BY` (or LIMIT) in a multi-table UPDATE statement.
>
> **< 10.3.2**
>
> It is **not** possible to use `ORDER BY` (or LIMIT) in a multi-table UPDATE statement.

> **CURRENT**
>
> MariaDB allows packed sort keys and values of non-sorted fields in the sort buffer. This can make filesort temporary files much smaller when `VARCHAR`, `CHAR` or `BLOB` columns are used, notably speeding up some `ORDER BY` sorts.
>
> **< 10.5**
>
> MariaDB does not allow packed sort keys and values of non-sorted fields in the sort buffer.

Examples

```
CREATE TABLE seq (i INT, x VARCHAR(1));
INSERT INTO seq VALUES (1,'a'), (2,'b'), (3,'b'), (4,'f'), (5,'e');

SELECT * FROM seq ORDER BY i;
+------+------+
| i    | x    |
+------+------+
|    1 | a    |
|    2 | b    |
|    3 | b    |
|    4 | f    |
|    5 | e    |
+------+------+

SELECT * FROM seq ORDER BY i DESC;
+------+------+
| i    | x    |
+------+------+
|    5 | e    |
|    4 | f    |
|    3 | b    |
|    2 | b    |
|    1 | a    |
+------+------+

SELECT * FROM seq ORDER BY x,i;
+------+------+
| i    | x    |
+------+------+
|    1 | a    |
|    2 | b    |
|    3 | b    |
|    5 | e    |
|    4 | f    |
+------+------+
```

`ORDER BY` in an UPDATE statement, in conjunction with LIMIT:

```
UPDATE seq SET x='z' WHERE x='b' ORDER BY i DESC LIMIT 1;

SELECT * FROM seq;
+------+------+
| i    | x    |
+------+------+
|    1 | a    |
|    2 | b    |
|    3 | z    |
|    4 | f    |
|    5 | e    |
+------+------+
```

`ORDER BY` can be used in a multi-table update:

```
CREATE TABLE warehouse (product_id INT, qty INT);
INSERT INTO warehouse VALUES (1,100),(2,100),(3,100),(4,100);

CREATE TABLE store (product_id INT, qty INT);
INSERT INTO store VALUES (1,5),(2,5),(3,5),(4,5);

UPDATE warehouse,store SET warehouse.qty = warehouse.qty-2, store.qty = store.qty+2
  WHERE (warehouse.product_id = store.product_id AND store.product_id  >= 1)
    ORDER BY store.product_id DESC LIMIT 2;

SELECT * FROM warehouse;
+------------+------+
| product_id | qty  |
+------------+------+
|          1 |  100 |
|          2 |  100 |
|          3 |   98 |
|          4 |   98 |
+------------+------+

SELECT * FROM store;
+------------+------+
| product_id | qty  |
+------------+------+
|          1 |    5 |
|          2 |    5 |
|          3 |    7 |
|          4 |    7 |
+------------+------+
```

PROCEDURE

The `PROCEDURE` clause of SELECT passes the whole result set to a Procedure which will process it. These Procedures are not Stored Procedures, and can only be written in the C language, so it is necessary to recompile the server.

Currently, the only available procedure is ANALYSE, which examines the resultset and suggests the optimal datatypes for each column. It is defined in the `sql/sql_analyse.cc` file, and can be used as an example to create

more Procedures.

This clause cannot be used in a view definition.

CURRENT

`[/*+ hints */]` syntax is available.

< 11.8

`[/*+ hints */]` syntax is **not** available.

CURRENT

Available join order hints can be found here.

< 12.0

Join order hints are **not** available.

CURRENT

`[/*+ MAX_EXECUTION_TIME( milliseconds ) */]` syntax is available.

The hint limits the time of statement execution to the number of milliseconds given in the hint argument.

< 12.0

`[/*+ MAX_EXECUTION_TIME( milliseconds ) */]` syntax is **not** available.

Description

`SELECT` is used to retrieve rows selected from one or more tables, and can include UNION statements and subqueries.

- Each `select_expr` expression indicates a column or data that you want to retrieve. You must have at least one select expression. See Select Expressions below.
- The `FROM` clause indicates the table or tables from which to retrieve rows. Use either a single table name or a `JOIN` expression. See JOIN for details. If no table is involved, FROM DUAL can be specified.
- Each table can also be specified as `db_name.tabl_name`. Each column can also be specified as `tbl_name.col_name` or even `db_name.tbl_name.col_name`. This allows one to write queries which involve multiple databases. See Identifier Qualifiers for syntax details.
- The `WHERE` clause, if given, indicates the condition or conditions that rows must satisfy to be selected. The `where_condition` is an expression that evaluates to true for each row to be selected. The statement selects all rows if there is no WHERE clause.
  - In the `WHERE` clause, you can use any of the functions and operators that MariaDB supports, except for aggregate (summary) functions. See Functions and Operators and Functions and Modifiers for use with GROUP BY (aggregate).
- Use the ORDER BY clause to order the results.
- Use the LIMIT clause to restrict the results to only a certain number of rows, optionally with an offset.
- Use the GROUP BY and `HAVING` clauses to group rows together when they have columns or computed values in common.

`SELECT` can also be used to retrieve rows computed without reference to any table.

Select Expressions

A `SELECT` statement must contain one or more select expressions, separated by commas. Each select expression can be one of the following:

- The name of a column.
- Any expression using functions and operators.
- `*` to select all columns from all tables in the `FROM` clause.
- `tbl_name.*` to select all columns from just the table `tbl_name`.

When specifying a column, you can either use just the column name or qualify the column name with the name of the table using `tbl_name.col_name`. The qualified form is useful if you are joining multiple tables in the `FROM` clause. If you do not qualify the column names when selecting from multiple tables, MariaDB will try to find the column in each table. It is an error if that column name exists in multiple tables.

You can quote column names using backticks. If you are qualifying column names with table names, quote each part separately as `tbl_name`.`col_name`.

If you use any grouping functions in any of the select expressions, all rows in your results will be implicitly grouped, as if you had used `GROUP BY NULL`. `GROUP BY NULL` being an expression behaves specially such that the entire result set is treated as a group.

DISTINCT

A query may produce some identical rows. By default, all rows are retrieved, even when their values are the same. To explicitly specify that you want to retrieve identical rows, use the `ALL` option. If you want duplicates to be removed from the result set, use the `DISTINCT` option. `DISTINCTROW` is a synonym for `DISTINCT`. See also COUNT DISTINCT and SELECT UNIQUE in Oracle mode.

INTO

The `INTO` clause is used to specify that the query results should be written to a file or variable.

- SELECT INTO OUTFILE - formatting and writing the result to an external file.
- SELECT INTO DUMPFILE - binary-safe writing of the unformatted results to an external file.
- SELECT INTO Variable - selecting and setting variables.

The reverse of `SELECT INTO OUTFILE` is LOAD DATA.

LIMIT

Restricts the number of returned rows. See LIMIT and LIMIT ROWS EXAMINED for details.

LOCK IN SHARE MODE/FOR UPDATE

See LOCK IN SHARE MODE and FOR UPDATE for details on the respective locking clauses.

OFFSET ... FETCH

> **CURRENT**
>
> See SELECT … OFFSET … FETCH.
>
> **< 10.6**
>
> The clause doesn't exist.

ORDER BY

Order a result set. See ORDER BY for details.

PARTITION

Specifies to the optimizer which partitions are relevant for the query. Other partitions will not be read. See Partition Pruning and Selection for details.

PROCEDURE

Passes the whole result set to a C Procedure. See PROCEDURE and PROCEDURE ANALYSE (the only built-in procedure not requiring the server to be recompiled).

SKIP LOCKED

> **CURRENT**
>
> This causes rows that couldn't be locked (LOCK IN SHARE MODE or FOR UPDATE) to be excluded from the result set. An explicit `NOWAIT` is implied here. This is only implemented on InnoDB tables and ignored otherwise.
>
> **< 10.6**
>
> The clause doesn't exist.

Optimizer Hints

These include HIGH_PRIORITY, STRAIGHT_JOIN, SQL_SMALL_RESULT | SQL_BIG_RESULT, SQL_BUFFER_RESULT, SQL_CACHE | SQL_NO_CACHE, and SQL_CALC_FOUND_ROWS.

See Optimizer Hints for details.

max_statement_time clause

By using max_statement_time in conjunction with SET STATEMENT, it is possible to limit the execution time of individual queries. For example:

```
SET STATEMENT max_statement_time=100 FOR
  SELECT field1 FROM table_name ORDER BY field1;
```

WAIT/NOWAIT

Set the lock wait timeout. See WAIT and NOWAIT.

Examples

```
SELECT f1,f2 FROM t1 WHERE (f3<=10) AND (f4='y');
```

See Getting Data from MariaDB (Beginner tutorial), or the various sub-articles, for more examples.

SELECT INTO DUMPFILE

Syntax

```
SELECT ... INTO DUMPFILE 'file_path'
```

Description

`SELECT ... INTO DUMPFILE` is a SELECT clause which writes the resultset into a single unformatted row, without any separators, in a file. The results will not be returned to the client.

file_path can be an absolute path, or a relative path starting from the data directory. It can only be specified as a string literal, not as a variable. However, the statement can be dynamically composed and executed as a prepared statement to work around this limitation.

This statement is binary-safe and so is particularly useful for writing BLOB values to file. It can be used, for example, to copy an image or an audio document from the database to a file.

The file must not exist. It cannot be overwritten. A user needs the FILE privilege to run this statement. Also, MariaDB needs permission to write files in the specified location. If the secure_file_priv system variable is set to a non-empty directory name, the file can only be written to that directory.

> **CURRENT**
>
> The character_set_filesystem system variable has controlled interpretation of file names that are given as literal strings.
>
> **< 5.1**
>
> The character_set_filesystem system variable does not have controlled interpretation of file names that are given as literal strings.

Example

```
SELECT _utf8'Hello world!' INTO DUMPFILE '/tmp/world';

SELECT LOAD_FILE('/tmp/world') AS world;
+--------------+
| world        |
+--------------+
| Hello world! |
+--------------+
```

See Also

- SELECT
- LOAD_FILE()
- SELECT INTO Variable
- SELECT INTO OUTFILE

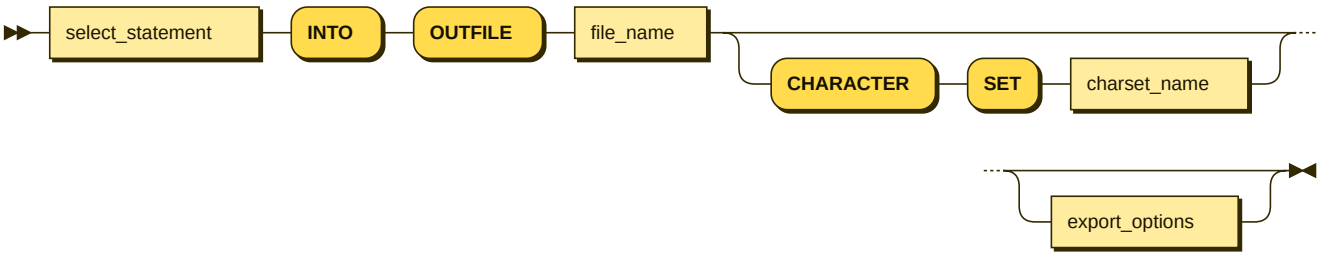
This page is licensed: CC BY-SA / Gnu FDL

SELECT INTO OUTFILE

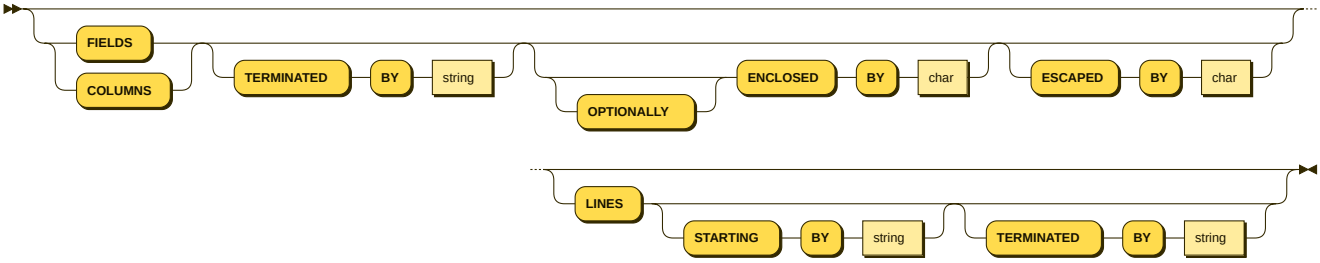
Syntax

```
SELECT ... INTO OUTFILE 'file_name'
        [CHARACTER SET charset_name]
        [export_options]

export_options:
    [{FIELDS | COLUMNS}
        [TERMINATED BY 'string']
        [[OPTIONALLY] ENCLOSED BY 'char']
        [ESCAPED BY 'char']
    ]
    [LINES
        [STARTING BY 'string']
        [TERMINATED BY 'string']
    ]
```



Railroad diagram of SELECT INTO OUTFILE — equivalent to the BNF above



Railroad diagram of export_options

Description

`SELECT INTO OUTFILE` writes the resulting rows to a file, and allows the use of column and row terminators to specify a particular output format. The default is to terminate fields with tabs () and lines with newlines ().

The file must not exist. It cannot be overwritten. A user needs the FILE privilege to run this statement. Also, MariaDB needs permission to write files in the specified location. If the secure_file_priv system variable is set to a non-empty directory name, the file can only be written to that directory or one of its subdirectories.

The LOAD DATA INFILE statement complements `SELECT INTO OUTFILE`.

Character Sets

The `CHARACTER SET` clause specifies the character set in which the results are to be written. Without the clause, no conversion takes place (the binary character set). In this case, if there are multiple character sets, the output will contain these too, and may not easily be able to be reloaded.

In cases where you have two servers using different character-sets, using `SELECT INTO OUTFILE` to transfer data from one to the other can have unexpected results. To ensure that MariaDB correctly interprets the escape sequences, use the `CHARACTER SET` clause on both the `SELECT INTO OUTFILE` statement and the subsequent LOAD DATA INFILE statement.

Example

The following example produces a file in the CSV format:

```
SELECT customer_id, firstname, surname FROM customer
  INTO OUTFILE '/exportdata/customers.txt'
  FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
  LINES TERMINATED BY '\n';
```

The following ANSI syntax is also supported for simple `SELECT` without `UNION` :

```
SELECT customer_id, firstname, surname INTO OUTFILE '/exportdata/customers.txt'
  FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
  LINES TERMINATED BY '\n'
  FROM customers;
```

If you want to use the ANSI syntax with `UNION` or similar construct you have to use the syntax:

```
SELECT  * INTO OUTFILE "/tmp/skr3"
FROM (SELECT * FROM t1 UNION SELECT * FROM t1);
```

This page is licensed: CC BY-SA / Gnu FDL

SELECT ... OFFSET ... FETCH

> **Note:**
>
> `SELECT ... OFFSET ... FETCH` is available from MariaDB 10.6.

Syntax

```
OFFSET start { ROW | ROWS }
FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } { ONLY | WITH TIES }
```

Description

The `OFFSET` clause allows one to return only those elements of a resultset that come after a specified offset. The `FETCH` clause specifies the number of rows to return, while `ONLY` or `WITH TIES` specifies whether or not to also return any further results that tie for last place according to the ordered resultset.

Either the singular `ROW` or the plural `ROWS` can be used after the `OFFSET` and `FETCH` clauses; the choice has no impact on the results.

`FIRST` and `NEXT` give the same result.

In the case of `WITH TIES`, an ORDER BY clause is required, otherwise an error will be returned.

```
SELECT i FROM t1 FETCH FIRST 2 ROWS WITH TIES;
ERROR 4180 (HY000): FETCH ... WITH TIES requires ORDER BY clause to be present
```

Examples

Given a table with 6 rows:

```
CREATE OR REPLACE TABLE t1 (i INT);
INSERT INTO t1 VALUES (1),(2),(3),(4), (4), (5);
SELECT i FROM t1 ORDER BY i ASC;
+------+
| i    |
+------+
|    1 |
|    2 |
|    3 |
|    4 |
|    4 |
|    5 |
+------+
```

`OFFSET 2` allows one to skip the first two results:

```
SELECT i FROM t1 ORDER BY i ASC OFFSET 2 ROWS;
+------+
| i    |
+------+
|    3 |
|    4 |
|    4 |
|    5 |
+------+
```

`FETCH FIRST 3 ROWS ONLY` limits the results to three rows only:

```
SELECT i FROM t1 ORDER BY i ASC OFFSET 1 ROWS FETCH FIRST 3 ROWS ONLY;
+------+
| i    |
+------+
|    2 |
|    3 |
|    4 |
+------+
```

The same outcome can also be achieved with the LIMIT clause:

```
SELECT i FROM t1 ORDER BY i ASC LIMIT 3 OFFSET 1;
+------+
| i    |
+------+
|    2 |
|    3 |
|    4 |
+------+
```

`WITH TIES` ensures the tied result `4` is also returned:

```
SELECT i FROM t1 ORDER BY i ASC OFFSET 1 ROWS FETCH FIRST 3 ROWS WITH TIES;
+------+
| i    |
+------+
|    2 |
|    3 |
|    4 |

SELECT WITH ROLLUP

Syntax

See SELECT.

Description

The `WITH ROLLUP` modifier adds extra rows to the result set that represent super-aggregate summaries. The super-aggregated column is represented by a `NULL` value. Multiple aggregates over different columns will be added if there are multiple `GROUP BY` columns.

The LIMIT clause can be used at the same time, and is applied after the `WITH ROLLUP` rows have been added.

`WITH ROLLUP` cannot be used with ORDER BY. Some sorting is still possible by using `ASC` or `DESC` clauses with the `GROUP BY` column, although the super-aggregate rows will always be added last.

Examples

These examples use the following sample table

```
CREATE TABLE booksales (
  country VARCHAR(35), genre ENUM('fiction','non-fiction'), year YEAR, sales INT);

INSERT INTO booksales VALUES
  ('Senegal','fiction',2014,12234), ('Senegal','fiction',2015,15647),
  ('Senegal','non-fiction',2014,64980), ('Senegal','non-fiction',2015,78901),
  ('Paraguay','fiction',2014,87970), ('Paraguay','fiction',2015,76940),
  ('Paraguay','non-fiction',2014,8760), ('Paraguay','non-fiction',2015,9030);
```

The `WITH ROLLUP` modifier in this example adds an extra row that aggregates both years:

```
SELECT year, SUM(sales) FROM booksales GROUP BY year;
+------+------------+
| year | SUM(sales) |
+------+------------+
| 2014 |     173944 |
| 2015 |     180518 |
+------+------------+
2 rows in set (0.08 sec)

SELECT year, SUM(sales) FROM booksales GROUP BY year WITH ROLLUP;
+------+------------+
| year | SUM(sales) |
+------+------------+
| 2014 |     173944 |
| 2015 |     180518 |
| NULL |     354462 |
+------+------------+
```

Each time the genre, the year, or the country change, another super-aggregate row is added:

```
SELECT country, year, genre, SUM(sales)
  FROM booksales GROUP BY country, year, genre;
+----------+------+-------------+------------+
| country  | year | genre       | SUM(sales) |
+----------+------+-------------+------------+
| Paraguay | 2014 | fiction     |      87970 |
| Paraguay | 2014 | non-fiction |       8760 |
| Paraguay | 2015 | fiction     |      76940 |
| Paraguay | 2015 | non-fiction |       9030 |
| Senegal  | 2014 | fiction     |      12234 |
| Senegal  | 2014 | non-fiction |      64980 |
| Senegal  | 2015 | fiction     |      15647 |
| Senegal  | 2015 | non-fiction |      78901 |
+----------+------+-------------+------------+

SELECT country, year, genre, SUM(sales)
  FROM booksales GROUP BY country, year, genre WITH ROLLUP;
+----------+------+-------------+------------+
| country  | year | genre       | SUM(sales) |
+----------+------+-------------+------------+
| Paraguay | 2014 | fiction     |      87970 |
| Paraguay | 2014 | non-fiction |       8760 |
| Paraguay | 2014 | NULL        |      96730 |
| Paraguay | 2015 | fiction     |      76940 |
| Paraguay | 2015 | non-fiction |       9030 |
| Paraguay | 2015 | NULL        |      85970 |
| Paraguay | NULL | NULL        |     182700 |
| Senegal  | 2014 | fiction     |      12234 |
| Senegal  | 2014 | non-fiction |      64980 |
| Senegal  | 2014 | NULL        |      77214 |
| Senegal  | 2015 | fiction     |      15647 |
| Senegal  | 2015 | non-fiction |      78901 |
| Senegal  | 2015 | NULL        |      94548 |
| Senegal  | NULL | NULL        |     171762 |
| NULL     | NULL | NULL        |     354462 |
+----------+------+-------------+------------+
```

The `LIMIT` clause, applied after `WITH ROLLUP`:

```
SELECT country, year, genre, SUM(sales)
  FROM booksales GROUP BY country, year, genre WITH ROLLUP LIMIT 4;
+----------+------+-------------+------------+
| country  | year | genre       | SUM(sales) |
+----------+------+-------------+------------+
| Paraguay | 2014 | fiction     |      87970 |
| Paraguay | 2014 | non-fiction |       8760 |
| Paraguay | 2014 | NULL        |      96730 |
| Paraguay | 2015 | fiction     |      76940 |
+----------+------+-------------+------------+
```

Sorting by year descending:

```
SELECT country, year, genre, SUM(sales)
  FROM booksales GROUP BY country, year DESC, genre WITH ROLLUP;
+----------+------+-------------+------------+
| country  | year | genre       | SUM(sales) |
+----------+------+-------------+------------+
| Paraguay | 2015 | fiction     |      76940 |
| Paraguay | 2015 | non-fiction |       9030 |
| Paraguay | 2015 | NULL        |      85970 |
| Paraguay | 2014 | fiction     |      87970 |
| Paraguay | 2014 | non-fiction |       8760 |
| Paraguay | 2014 | NULL        |      96730 |
| Paraguay | NULL | NULL        |     182700 |
| Senegal  | 2015 | fiction     |      15647 |
| Senegal  | 2015 | non-fiction |      78901 |
| Senegal  | 2015 | NULL        |      94548 |
| Senegal  | 2014 | fiction     |      12234 |
| Senegal  | 2014 | non-fiction |      64980 |
| Senegal  | 2014 | NULL        |      77214 |
| Senegal  | NULL | NULL        |     171762 |
| NULL     | NULL | NULL        |     354462 |
+----------+------+-------------+------------+
```

Common Table Expressions (CTE)

See Recursive Common Table Expressions Overview.

Process hierarchical data using recursive CTEs. These expressions reference themselves to repeatedly execute a subquery, perfect for traversing tree structures or generating sequences.

See Non-Recursive Common Table Expressions Overview.

Define simple temporary result sets. Non-recursive CTEs act like query-local views, improving readability by allowing you to define and reuse subqueries within a single statement.

See WITH.

Complete WITH clause reference: WITH [RECURSIVE] AS (SELECT…) syntax, recursive CTE support, CYCLE… RESTRICT cycle detection, and max_recursive_iterations.

Recursive Common Table Expressions Overview

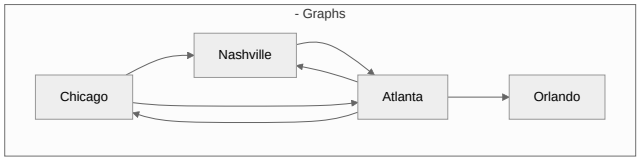
Common Table Expressions (CTEs) are a standard SQL feature, and are essentially temporary named result sets. They are defined using the `WITH` clause and can be referenced like tables within the main query. CTEs first appeared in the SQL standard in 1999, and the first implementations began appearing in 2007.

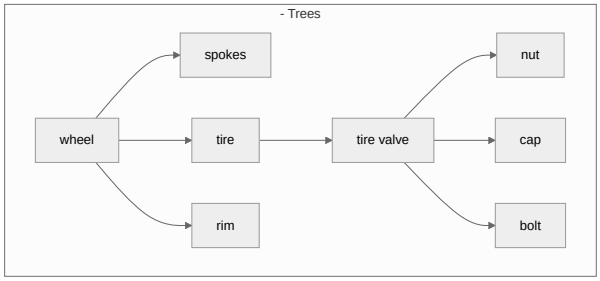
MariaDB supports two types of CTEs:

- Non-recursive;
- Recursive, which this article covers.

Recursive CTE

A recursive CTE will repeatedly execute subsets of the data until it obtains the complete result set. This makes it particularly useful for handling hierarchical or tree-structured data, such as organizational charts, category trees, or parent-child relationships. max_recursive_iterations avoids infinite loops. CTEs permit a query to reference itself. SQL is generally poor at recursive structures.



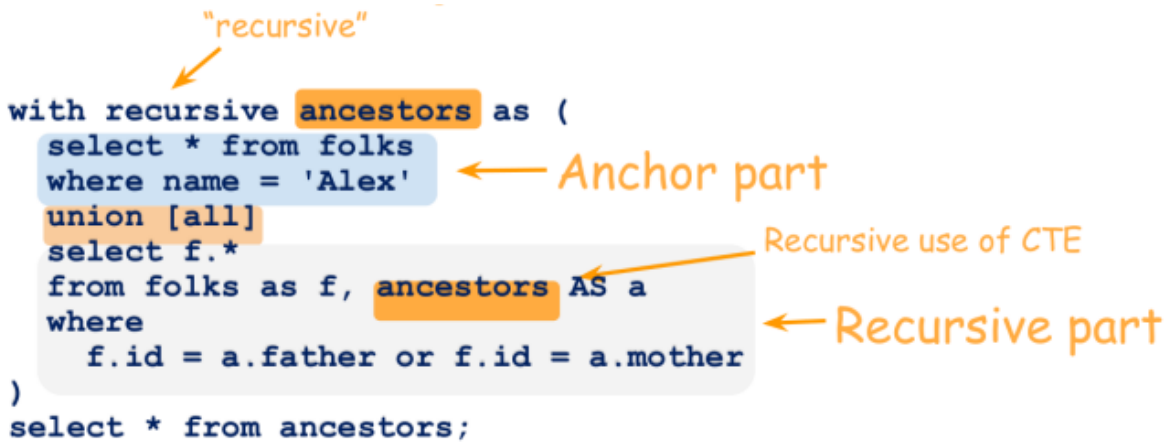


A tree has exactly one path from root to any node, while a graph can have multiple paths and cycles, such as the bidirectional Chicago-Atlanta and Nashville-Atlanta connections.

Recursive CTE Syntax

WITH RECURSIVE signifies a recursive CTE. It is given a name, followed by a body (the main query). The body consists of two parts:

- An anchor member (the initial query)
- A recursive member (which references the CTE itself).



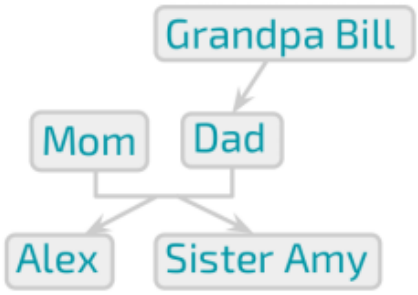
rcte_syntax

Computation

Given the following structure:

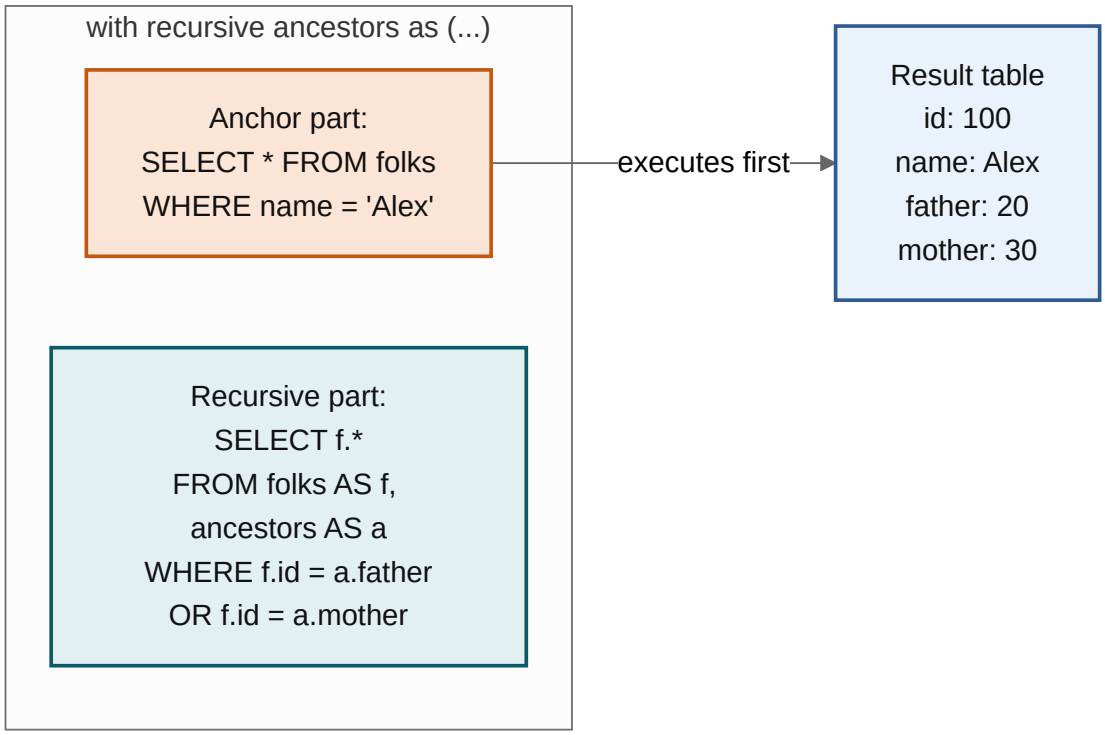
Recursive CTE computation

id	name	father	mother
100	Alex	20	30
20	Dad	10	NULL
30	Mom	NULL	NULL
10	Grandpa Bill	NULL	NULL
98	Sister Amy	20	30



rcte_computation

1. First execute the anchor part of the query:



Step #1: executing only the anchor part of the query returns the result table's single row — id 100, name Alex, father 20, mother 30.

2. Next, execute the recursive part of the query:

Computation

Result table

id	name	father	mother
100	Alex	20	30

```
with recursive ancestors as (
  select * from folks
  where name = 'Alex'
  union
  select f.*
  from folks as f, ancestors AS a
  where
    f.id = a.father or f.id = a.mother
)
select * from ancestors;
```

id	name	father	mother
100	Alex	20	30
20	Dad	10	NULL
30	Mom	NULL	NULL
10	Grandpa Bill	NULL	NULL
98	Sister Amy	20	30

Step #2:
execution of the recursive part

rcte_computation_2

Computation

Result table

id	name	father	mother
100	Alex	20	30
20	Dad	10	NULL
30	Mom	NULL	NULL

```
with recursive ancestors as (
  select * from folks
  where name = 'Alex'
  union
  select f.*
  from folks as f, ancestors AS a
  where
    f.id = a.father or f.id = a.mother
)
select * from ancestors;
```

id	name	father	mother
100	Alex	20	30
20	Dad	10	NULL
30	Mom	NULL	NULL
10	Grandpa Bill	NULL	NULL
98	Sister Amy	20	30

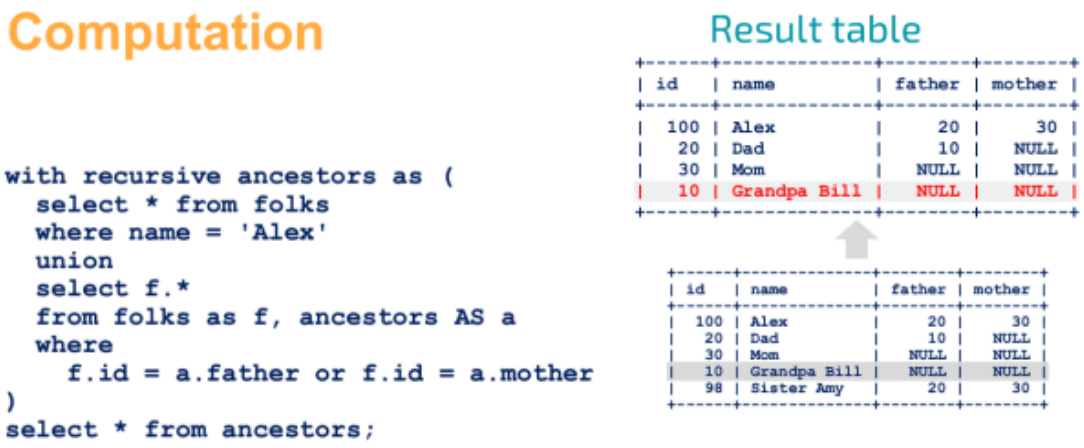
Computation

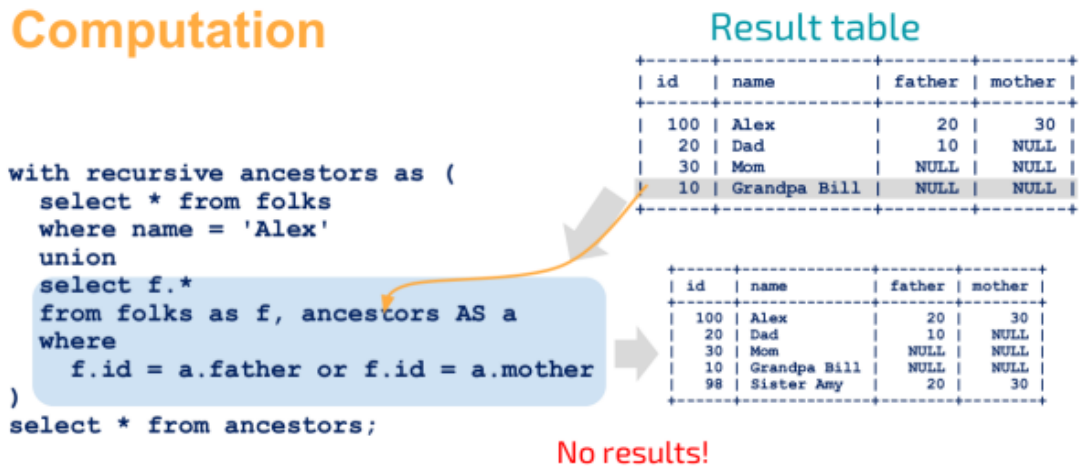
Result table

id	name	father	mother
100	Alex	20	30
20	Dad	10	NULL
30	Mom	NULL	NULL

```
with recursive ancestors as (
  select * from folks
  where name = 'Alex'
  union
  select f.*
  from folks as f, ancestors AS a
  where
    f.id = a.father or f.id = a.mother
)
select * from ancestors;
```

id	name	father	mother
100	Alex	20	30
20	Dad	10	NULL
30	Mom	NULL	NULL
10	Grandpa Bill	NULL	NULL
98	Sister Amy	20	30





Summary

```
WITH RECURSIVE R AS (
  SELECT anchor_data
  UNION [all]
  SELECT recursive_part
  FROM R, ...
)
SELECT ...
```

1. Compute anchor_data.
2. Compute recursive_part to get the new data.
3. If (new data is non-empty) go to 2.

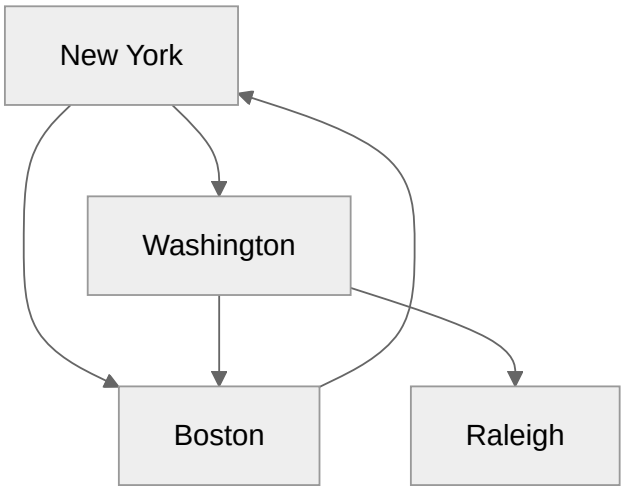
Recursive CTE Examples

Transitive closure - determining bus destinations

Sample data:

origin	dst
New York	Boston
Boston	New York
New York	Washington
Washington	Boston

origin	dst
Washington	Raleigh



The `bus_routes` table as a directed graph: New York and Boston connect both ways, while New York → Washington → Boston/Raleigh are one-way routes.

```
CREATE TABLE bus_routes (origin VARCHAR(50), dst VARCHAR(50));
INSERT INTO bus_routes VALUES
  ('New York', 'Boston'),
  ('Boston', 'New York'),
  ('New York', 'Washington'),
  ('Washington', 'Boston'),
  ('Washington', 'Raleigh');
```

Now, we want to return the bus destinations with New York as the origin:

```
WITH RECURSIVE bus_dst as (
    SELECT origin as dst FROM bus_routes WHERE origin='New York'
  UNION
    SELECT bus_routes.dst FROM bus_routes JOIN bus_dst ON bus_dst.dst= bus_routes.origin
)
SELECT * FROM bus_dst;
+------------+
| dst        |
+------------+
| New York   |
| Boston     |
| Washington |
| Raleigh    |
+------------+
```

The above example is computed as follows:

First, the anchor data is calculated:

- Starting from New York.
- Boston and Washington are added.

Next, the recursive part:

- Starting from Boston and then Washington.
- Raleigh is added.
- UNION excludes nodes that are already present.

Computing paths - determining bus routes

This time, we are trying to get bus routes such as “New York -> Washington -> Raleigh”.

Using the same sample data as the previous example:

```
WITH RECURSIVE paths (cur_path, cur_dest) AS (
    SELECT origin, origin FROM bus_routes WHERE origin='New York'
  UNION
    SELECT CONCAT(paths.cur_path, ',', bus_routes.dst), bus_routes.dst
     FROM paths
     JOIN bus_routes
       ON paths.cur_dest = bus_routes.origin AND
         NOT FIND_IN_SET(bus_routes.dst, paths.cur_path)
)
SELECT * FROM paths;
+-----------------------------+------------+
| cur_path                    | cur_dest   |
+-----------------------------+------------+
| New York                    | New York   |
| New York,Boston             | Boston     |
| New York,Washington         | Washington |
| New York,Washington,Boston  | Boston     |
| New York,Washington,Raleigh | Raleigh    |
+-----------------------------+------------+
```

Type Resolution and Data Truncation

In previous versions of MariaDB, the data type of a Recursive CTE column was entirely determined by the Anchor (non-recursive) part. If the Recursive part carried out calculations that generated a greater value, the data was silently truncated, leading to incorrect results.

Starting with the versions listed below, MariaDB prevents silent data loss. The server now validates that the data generated by the recursive part matches the column types given by the anchor part. If a mismatch that leads to truncation is detected, the query will now fail with an error. See MDEV-12325 for more information.

MariaDB Series	Fixed Version
10.3	10.3.36
10.4	10.4.26
10.5	10.5.17
10.6	10.6.9
10.7	10.7.5

Example: Managing Out of Range Errors in Recursive Part

MariaDB now detects an error when a recursive part executes a calculation (such as adding a large offset) that exceeds the anchor part’s data type capacity. To ensure that the query succeeds, CAST can be used in the anchor part to declare a column size that will allow for the expected growth of your recursive calculations.

Consider a table representing a company employee hierarchy:

```
CREATE TABLE t1
(
  id INT,     -- employee ID
  mid INT,    -- manager ID, or NULL if top level employee
  name TEXT   -- employee name
);
INSERT INTO t1 VALUES (0,NULL, 'Name');
INSERT INTO t1 VALUES (1,0,    'Name1');
INSERT INTO t1 VALUES (2,0,    'Name2');
INSERT INTO t1 VALUES (11,1,   'Name11');
INSERT INTO t1 VALUES (12,1,   'Name12');
```

The following recursive CTE attempts to generate hierarchy levels by changing the mid value in the recursive part:

```
WITH RECURSIVE
cteReports (level, id, mid, name) AS
(
  SELECT 1, id, mid, name FROM t1 WHERE mid IS NULL
  UNION ALL
  SELECT r.level + 1, e.id, e.mid + 1000000000000, e.name FROM t1 e
  INNER JOIN cteReports r ON e.mid = r.id
)
SELECT
  level, id, mid, name,
  (SELECT name FROM t1 WHERE id= cteReports.mid) AS mname
FROM cteReports
ORDER BY level, mid;
```

This query fails with an error with MariaDB versions that incorporate the fix for MDEV-12325:

```
Error 1264 (22003): Out of range value for column 'mid' in 'cteReports'
```

This happens because the anchor member selects `mid` as the standard integer, but the recursive part attempts to add `1000000000000`, which exceeds the `INT` limit.

To avoid this error, the data type must be widened (for example, to `DOUBLE` or `BIGINT`) in the anchor part, since recursive CTE column types are defined there.

```
WITH RECURSIVE
cteReports (level, id, mid, name) AS
(
  SELECT 1, id, cast(mid as double), name FROM t1 WHERE mid IS NULL
  UNION ALL
  SELECT r.level + 1, e.id, e.mid + 1000000000000, e.name FROM t1 e
   INNER JOIN cteReports r ON e.mid = r.id
)
SELECT
  level, id, mid, name,
  (SELECT name FROM t1 WHERE id= cteReports.mid) AS mname
FROM cteReports
ORDER BY level, mid;
```

By explicitly widening the data type in the anchor part, all values generated by the recursive part fit within the defined column type, and the query executes successfully.

The expected query result would be:

```
+-------+------+---------------+--------+--------+
| level | id   | mid           | name   | mname  |
+-------+------+---------------+--------+--------+
|     1 |    0 | NULL          | Name   | NULL   |
|     2 |    1 | 1000000000000 | Name1  | NAME   |
|     2 |    2 | 1000000000000 | Name2  | NAME   |
|     3 |   11 | 1000000000001 | Name11 | NAME1  |
|     3 |   12 | 1000000000001 | Name12 | NAME1  |
+-------+------+------------+--------+-----------+
```

Non-Recursive Common Table Expressions Overview

Common Table Expressions (CTEs) are a standard SQL feature, and are essentially temporary named result sets. There are two kinds of CTEs: Non-Recursive, which this article covers; and Recursive.

Non-Recursive CTEs

The WITH keyword signifies a CTE. It is given a name, followed by a body (the main query).

CTEs are similar to derived tables:

```
WITH engineers AS
   ( SELECT * FROM employees
     WHERE dept = 'Engineering' )

SELECT * FROM engineers
WHERE ...
```

```
SELECT * FROM
   ( SELECT * FROM employees
     WHERE dept = 'Engineering' ) AS engineers
WHERE
...
```

A non-recursive CTE is basically a query-local VIEW. There are several advantages and caveats to them. The syntax is more readable than a nested `FROM (SELECT ...)`.
A CTE can refer to another and it can be referenced from multiple places.

A CTE referencing Another CTE

Using this format makes for a more readable SQL than a nested `FROM(SELECT ...)` clause:

```
WITH engineers AS (
SELECT * FROM employees
WHERE dept IN('Development','Support') ),
eu_engineers AS ( SELECT * FROM engineers WHERE country IN('NL',...) )
SELECT
...
FROM eu_engineers;
```

Multiple Uses of a CTE

This can be an ‘anti-self join’, for example:

```
WITH engineers AS (
SELECT * FROM employees
WHERE dept IN('Development','Support') )

SELECT * FROM engineers E1
WHERE NOT EXISTS
   (SELECT 1 FROM engineers E2
    WHERE E2.country=E1.country
    AND E2.name <> E1.name );
```

Or, for year-over-year comparisons, for example:

```
WITH sales_product_year AS (
SELECT product, YEAR(ship_date) AS year,
SUM(price) AS total_amt
FROM item_sales
GROUP BY product, year )

SELECT *
FROM sales_product_year CUR,
sales_product_year PREV,
WHERE CUR.product=PREV.product
AND  CUR.year=PREV.year + 1
AND CUR.total_amt > PREV.total_amt
```

Another use is to compare individuals against their group. Below is an example of how this might be executed:

```
WITH sales_product_year AS (
SELECT product,
YEAR(ship_date) AS year,
SUM(price) AS total_amt
FROM item_sales
GROUP BY product, year
)

SELECT *
FROM sales_product_year S1
WHERE
total_amt >
    (SELECT 0.1 * SUM(total_amt)
     FROM sales_product_year S2
     WHERE S2.year = S1.year)
```

This page is licensed: CC BY-SA / Gnu FDL

WITH

Syntax

```
WITH [RECURSIVE] table_reference [(columns_list)] AS  (
  SELECT ...
)
[CYCLE cycle_column_list RESTRICT]
SELECT ...
```

Description

The `WITH` keyword signifies a Common Table Expression (CTE). It allows you to refer to a subquery expression many times in a query, as if having a temporary table that only exists for the duration of a query.

There are two kinds of CTEs:

- Non-Recursive.

- Recursive (signified by the `RECURSIVE` keyword).

You can use `table_reference` as any normal table in the external `SELECT` part. You can also use `WITH` in subqueries, as well as with EXPLAIN and SELECT.

Poorly-formed recursive CTEs can in theory cause infinite loops. The max_recursive_iterations system variable limits the number of recursions.

CYCLE ... RESTRICT

CURRENT

The `CYCLE` clause enables CTE cycle detection, avoiding excessive or infinite loops,
MariaDB supports a relaxed, non-standard grammar.
The SQL Standard permits a `CYCLE` clause, as follows:

```
WITH RECURSIVE ... (
  ...
)
CYCLE <cycle column list>
SET <cycle mark column> TO <cycle mark value> DEFAULT <non-cycle mark value>
USING <path column>
```

where all clauses are mandatory.
MariaDB does not support this, but permits a non-standard relaxed grammar, as follows:

```
WITH RECURSIVE ... (
  ...
)
CYCLE <cycle column list> RESTRICT
```

With the use of `CYCLE ... RESTRICT` it makes no difference whether the CTE uses `UNION ALL` or `UNION DISTINCT` anymore. `UNION ALL` means “all rows, but without cycles”, which is exactly what the `CYCLE` clause enables. And `UNION DISTINCT` means all rows should be different, which, again, is what will happen — as uniqueness is enforced over a subset of columns, complete rows will automatically all be different.

< 10.5.2

`CYCLE ... RESTRICT` is not available.

Examples

Below is an example with the `WITH` at the top level:

```
WITH t AS (SELECT a FROM t1 WHERE b >= 'c')
  SELECT * FROM t2, t WHERE t2.c = t.a;
```

The example below uses `WITH` in a subquery:

```
SELECT t1.a, t1.b FROM t1, t2
  WHERE t1.a > t2.c
     AND t2.c IN(WITH t AS (SELECT * FROM t1 WHERE t1.a < 5)
                 SELECT t2.c FROM t2, t WHERE t2.c = t.a);
```

Below is an example of a Recursive CTE:

```
WITH RECURSIVE ancestors AS
 ( SELECT * FROM folks
   WHERE name="Alex"
   UNION
   SELECT f.*
   FROM folks AS f, ancestors AS a
   WHERE f.id = a.father OR f.id = a.mother )
SELECT * FROM ancestors;
```

Consider the following structure and data:

```
CREATE TABLE t1 (from_ int, to_ int);
INSERT INTO t1 VALUES (1,2), (1,100), (2,3), (3,4), (4,1);
SELECT * FROM t1;
+-------+------+
| from_ | to_  |
+-------+------+
|     1 |    2 |
|     1 |  100 |
|     2 |    3 |
|     3 |    4 |
|     4 |    1 |
+-------+------+
```

Given the above, the following query would theoretically result in an infinite loop due to the last record in t1 (note that max_recursive_iterations is set to 10 for the purposes of this example, to avoid the excessive number of cycles):

```
SET max_recursive_iterations=10;

WITH RECURSIVE cte (depth, from_, to_) AS (
  SELECT 0,1,1 UNION DISTINCT SELECT depth+1, t1.from_, t1.to_
    FROM t1, cte  WHERE t1.from_ = cte.to_
)
SELECT * FROM cte;
+-------+-------+------+
| depth | from_ | to_  |
+-------+-------+------+
|     0 |     1 |    1 |
|     1 |     1 |    2 |
|     1 |     1 |  100 |
|     2 |     2 |    3 |
|     3 |     3 |    4 |
|     4 |     4 |    1 |
|     5 |     1 |    2 |
|     5 |     1 |  100 |
|     6 |     2 |    3 |
|     7 |     3 |    4 |
|     8 |     4 |    1 |
|     9 |     1 |    2 |
|     9 |     1 |  100 |
|    10 |     2 |    3 |
+-------+-------+------+
```

However, the `CYCLE ... RESTRICT` clause can overcome this:

```
WITH RECURSIVE cte (depth, from_, to_) AS (
  SELECT 0,1,1 UNION SELECT depth+1, t1.from_, t1.to_
    FROM t1, cte WHERE t1.from_ = cte.to_
)
CYCLE from_, to_ RESTRICT
SELECT * FROM cte;
+-------+-------+------+
| depth | from_ | to_  |
+-------+-------+------+
|     0 |     1 |    1 |
|     1 |     1 |    2 |
|     1 |     1 |  100 |
|     2 |     2 |    3 |
|     3 |     3 |    4 |
|     4 |     4 |    1 |

JOIN Syntax

> **Note:**
>
> For an introduction to joins, see Joining Tables with JOIN Clauses Guide.

Description

MariaDB supports the following `JOIN` syntaxes for the `table_references` part of SELECT statements and multiple-table DELETE and UPDATE statements:

```
table_references:
    table_reference [, table_reference] ...

table_reference:
    table_factor
  | join_table

table_factor (<= MariaDB 11.6):
    tbl_name [PARTITION (partition_list)]
        [query_system_time_period_specification] [[AS] alias] [index_hint_list]
  | table_subquery [query_system_time_period_specification] [AS] alias
  | ( table_references )
  | { OJ table_reference LEFT OUTER JOIN table_reference
        ON conditional_expr }

table_factor (>= MariaDB 11.7):
    tbl_name [PARTITION (partition_list)]
        [query_system_time_period_specification] [[AS] alias] [index_hint_list]
  | table_subquery [query_system_time_period_specification] [AS] alias [(column_name_list)]
  | ( table_references )
  | { OJ table_reference LEFT OUTER JOIN table_reference
        ON conditional_expr }

join_table:
    table_reference [INNER | CROSS] JOIN table_factor [join_condition]
  | table_reference STRAIGHT_JOIN table_factor
  | table_reference STRAIGHT_JOIN table_factor ON conditional_expr
  | table_reference {LEFT|RIGHT} [OUTER] JOIN table_reference join_condition
  | table_reference NATURAL [{LEFT|RIGHT} [OUTER]] JOIN table_factor

join_condition:
    ON conditional_expr
  | USING (column_list)

query_system_time_period_specification:
    FOR SYSTEM_TIME AS OF point_in_time
  | FOR SYSTEM_TIME BETWEEN point_in_time AND point_in_time
  | FOR SYSTEM_TIME FROM point_in_time TO point_in_time
  | FOR SYSTEM_TIME ALL

point_in_time:
    [TIMESTAMP] expression
  | TRANSACTION expression

index_hint_list:
    index_hint [, index_hint] ...

index_hint:
    USE {INDEX|KEY}
      [{FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])
  | IGNORE {INDEX|KEY}
      [{FOR {JOIN|ORDER BY|GROUP BY}] (index_list)
  | FORCE {INDEX|KEY}
      [{FOR {JOIN|ORDER BY|GROUP BY}] (index_list)

index_list:
    index_name [, index_name] ...
```

A *table reference* is also known as a *join expression*.

Each table can also be specified as `db_name`.`tabl_name`. This allows to write queries which involve multiple databases. See Identifier Qualifiers for syntax details.

The syntax of `table_factor` is an extension to the SQL Standard. The latter accepts only `table_reference`, not a list of them inside a pair of parentheses.

This is a conservative extension if we consider each comma in a list of table_reference items as equivalent to an inner join. Consider this query:

```
SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
                ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

It is equivalent to this query:

```
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
                ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

> **Note:**
>
> In MariaDB, `CROSS JOIN` is a syntactic equivalent to `INNER JOIN` (they can replace each other). In standard SQL, they are not equivalent. `INNER JOIN` is used with an `ON` clause, `CROSS JOIN` is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. MariaDB also supports nested joins (see Nested Join Optimization).

Subqueries

A table subquery is specified as a parenthesized query and must contain a following derived table name (specified as *alias* in the above syntax specification).

CURRENT

You can optionally specify a list of column names in parenthesis.

```
SELECT ic1, ic2, ic3 FROM
      (
        SELECT c1, c2, c3 FROM t1 GROUP BY c1
      ) dt2 (ic1, ic2, ic3)
    JOIN t2 ON t2.c1 = dt2.ic1
    WHERE c2 > 0
    GROUP BY ic1
```

Here, the table subquery for t1 will be materialized and named dt2, with column names ic1, ic2, ic3. These column names are used outside the subquery.

< 11.7

You **cannot** optionally specify a list of column names in parenthesis.

See also Correlation Column List.

System-Versioned Tabled

See System-versioned tables for more information about the `FOR SYSTEM_TIME` syntax.

Index Hints

Index hints can be specified to affect how the MariaDB optimizer makes use of indexes. For more information, see How to force query plans.

Oracle Mode

> **Note:**
>
> This feature is available from MariaDB 12.1.

Overview

When Oracle mode is active, the Oracle-style `(+)` syntax can be used. For example, the following two queries are identical:

```
SELECT * FROM t1 LEFT JOIN t2 ON t1.a = t2.b;
```

```
SELECT * FROM t1, t2 WHERE t1.a = t2.b(+);
```

Similarly, the following two queries are identical:

```
SELECT * FROM t1 RIGHT JOIN t2 ON t1.a = t2.b;
```

```
SELECT * FROM t1, t2 WHERE t1.a(+) = t2.b;
```

With more than two tables, these two queries are identical:

```
SELECT * FROM t1 LEFT JOIN t2 ON t1.a = t2.a LEFT JOIN t3 ON t2.a = t3.a
```

```
SELECT * FROM t1, t2, t3 WHERE t1.a = t2.a(+) AND t2.a = t3.a(+)
```

To "rewrite" a join query using the `(+)` syntax, use EXPLAIN EXTENDED (the last line is an approximation at using the "regular" `LEFT JOIN` syntax):

```
EXPLAIN EXTENDED
    SELECT * FROM t1, t2, t3 WHERE t1.a = t2.a(+) AND t2.a = t3.a(+);
id  select_type table   type    possible_keys   key key_len ref rows    filtered    Extra
1   SIMPLE  t1  ALL NULL    NULL    NULL    NULL    3   100.00
1   SIMPLE  t2  ALL NULL    NULL    NULL    NULL    3   100.00  Using where; Using join buffer (flat, BNL
join)
1   SIMPLE  t3  ALL NULL    NULL    NULL    NULL    3   100.00  Using where; Using join buffer
(incremental, BNL join)
Warnings:
Note    1003    select "test"."t1"."a" AS "a","test"."t2"."a" AS "a","test"."t3"."a" AS "a" from
"test"."t1" left join "test"."t2" on("test"."t2"."a" = "test"."t1"."a") left join "test"."t3"
on("test"."t3"."a" = "test"."t2"."a") where 1
```

Limitations

The table whose columns are marked with the `(+)` operator in a subexpression (a part of the `WHERE` clause divided by `AND`) are the **inner part** of the expression. A table whose columns are not marked with the operator belong to the **outer part**.

Example of a single subexpression within a `WHERE` clause:

```
... WHERE t1.a = t2.a(+)
```

Example of two subexpressions within a `WHERE` clause – here, both `t1.a = t2.a(+)` and `t2.a = t3.a(+)` are inner parts, because both contain a `(+)` operator:

```
... WHERE t1.a = t2.a(+) AND t2.a = t3.a(+)
```

Example of two subexpressions within a `WHERE` clause – here, `t1.a = t2.a(+)` is the inner part (because of the `(+)` operator), and `t2.a = 42` is the outer part (it doesn't have a `(+)` operator:

```
... WHERE t1.a = t2.a(+) AND t2.a = 42
```

"Rewritten" as a "regular" join, that clause looks like this:

```
... FROM t1 LEFT JOIN t2 ON (t1.a = t2.a) WHERE t2.a = 42
```

The following limitations apply:

- The `(+)` operator can only be used in a `WHERE` clause.
- The `(+)` operator can only be applied to a table column, and the column should be from the local `SELECT`, not from an outer `SELECT`.
- The `(+)` operator cannot be used with other `JOIN` methods – it must be a comma-separated list in the `FROM` clause.
- When the `WHERE` clause combines subexpressions with `OR`, the `(+)` operator cannot be used.
- The `(+)` operator cannot be used on the right side of an `IN` function.
- The `(+)` operator cannot be used in row operations.
- The `(+)` operator cannot be used when two or more tables are on one side of and marked with the `(+)` operator and some are not.
- The `(+)` operator cannot create loops (or cycles) of dependence, where the same table appears on both sides of the operator in one expression, or through a chain of expressions.

Error Codes

The following errors may occur when not adhering to the `(+)` operator limitations or for other reasons:

- `ER_INVALID_USE_OF_ORA_JOIN`
- `ER_INVALID_USE_OF_ORA_JOIN_OUTER_REF`
- `ER_INVALID_USE_OF_ORA_JOIN_WRONG_FUNC`
- `ER_INVALID_USE_OF_ORA_JOIN_ONE_TABLE`
- `ER_INVALID_USE_OF_ORA_JOIN_CYCLE`
- `ER_INVALID_USE_OF_ORA_JOIN_MIX`
- `WARN_ORA_JOIN_IGNORED`

You can find examples of the errors by error code in these files (which are available on GitHub):

- `mysql-test/suite/compat/oracle/t/ora_outer_join.test`
- `mysql-test/suite/compat/oracle/t/ora_outer_join_err.test`

Examples

```
SELECT left_tbl.*
  FROM left_tbl LEFT JOIN right_tbl ON left_tbl.id = right_tbl.id
  WHERE right_tbl.id IS NULL;
```

Comma vs JOIN

A query to retrieve the list of phone numbers for clients who ordered in the last two weeks might be written in a couple of ways. Here are two:

```
SELECT *
FROM
  clients,
  orders,
  phoneNumbers
WHERE
  clients.id = orders.clientId
  AND clients.id = phoneNumbers.clientId
  AND orderPlaced >= NOW() - INTERVAL 2 WEEK;
```

```
SELECT *
FROM
  clients
  INNER JOIN orders ON clients.id = orders.clientId
  INNER JOIN phoneNumbers ON clients.id = phoneNumbers.clientId
WHERE
  orderPlaced >= NOW() - INTERVAL 2 WEEK;
```

Does it make a difference? Not much as written. But you should use the second form, for these reasons:

- Readability. Once the `WHERE` clause contains more than two conditions, it becomes tedious to pick out the difference between business logic (only dates in the last two weeks) and relational logic (which fields relate clients to orders). Using the `JOIN` syntax with an `ON` clause makes the `WHERE` list shorter, and makes it very easy to see how tables relate to each other.
- Flexibility. Let's say we need to see all clients even if they don't have a phone number in the system. With the second version, it's easy; just change `INNER JOIN phoneNumbers` to `LEFT JOIN phoneNumbers`. Try that with the first version, and MariaDB will raise an `ER_BAD_FIELD_ERROR` ("Unknown column") error when the query executes, because the change in precedence between the comma operator and the `JOIN` keyword means the `ON` clause can no longer resolve columns from the comma-joined table. The solution is to rearrange the `FROM` clause or add parentheses to override the precedence, and that quickly becomes frustrating.
- Portability. If your queries use standard SQL syntax, you will have an easier time switching to a different database should the need ever arise.

Set Operations

See Precedence Control in Table Operations.

Control the execution order of UNION, EXCEPT, and INTERSECT operations. Learn how to use parentheses to define explicit operation priority.

See EXCEPT.

Return rows from the first result set that do not appear in the second. This set operator performs a subtraction of two datasets.

See INTERSECT.

Return only the rows that appear in both result sets. INTERSECT implicitly applies DISTINCT and follows the same column-naming, ORDER BY, and LIMIT rules as UNION.

See MINUS.

Oracle-compatible synonym for the EXCEPT operator. It returns rows from the first query that are not present in the second query.

See UNION.

Combine results from multiple SELECT statements into a single result set. This operator can optionally remove duplicates or include all rows.

This page is licensed: CC BY-SA / Gnu FDL

Precedence Control in Table Operations

You can control the ordering of execution on table operations using parentheses.

Syntax

```
(  expression )
[ORDER BY [column[, column...]]]
[LIMIT {[offset,] row_count | row_count OFFSET offset}]
```

Description

Using parentheses in SQL allows to control the order of execution for SELECT statements and Table Value Constructor, including UNION, EXCEPT, and INTERSECT operations. MariaDB executes the parenthetical expression before the rest of the statement. You can then use ORDER BY and LIMIT clauses the further organize the result set.

> **Note:**
>
> The Optimizer may rearrange the exact order in which MariaDB executes different parts of the statement. When it calculates the result set, however, it returns values as though the parenthetical expression were executed first.

Example

```
CREATE TABLE test.t1 (num INT);

INSERT INTO test.t1 VALUES (1),(2),(3);

(SELECT * FROM test.t1
 UNION
 VALUES (10))
INTERSECT
VALUES (1),(3),(10),(11);
+------+
| num  |
+------+
|    1 |
|    3 |
|   10 |
+------+

((SELECT * FROM test.t1
  UNION
  VALUES (10))
 INTERSECT
 VALUES (1),(3),(10),(11))
ORDER BY 1 DESC;
+------+
| num  |
+------+
|   10 |
|    3 |
|    1 |
+------+
```

This page is licensed: CC BY-SA / Gnu FDL

EXCEPT

EXCEPT

The result of `EXCEPT` contains all records of the left `SELECT` result set except records which are in right `SELECT` result set. In other words, it is the subtraction of two result sets.

> **CURRENT**
>
> `MINUS` is a synonym when SQL_MODE=ORACLE is set.
>
> **< 10.6.1**
>
> `MINUS` is a synonym is not available.

Syntax

```
SELECT ...
(INTERSECT [ALL | DISTINCT] | EXCEPT [ALL | DISTINCT] | UNION [ALL | DISTINCT])
  SELECT ...
[(INTERSECT [ALL | DISTINCT] | EXCEPT [ALL | DISTINCT] | UNION [ALL | DISTINCT])
  SELECT ...]
[ORDER BY [{col_name | expr | position} [ASC | DESC]
  [, {col_name | expr | position} [ASC | DESC] ...]]]
[LIMIT {[offset,] row_count | row_count OFFSET offset}
| OFFSET start { ROW | ROWS }
| FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } { ONLY | WITH TIES } ]
```

Description

MariaDB supports `EXCEPT` and INTERSECT in addition to UNION.

The queries before and after `EXCEPT` must be SELECT or VALUES statements.

All behavior for naming columns, `ORDER BY` and `LIMIT` is the same as for UNION. Note that the alternative SELECT … OFFSET … FETCH syntax is only supported. This allows us to use the `WITH TIES` clause.

`EXCEPT` implicitly supposes a `DISTINCT` operation.

The result of `EXCEPT` is all records of the left `SELECT` result except records which are in right `SELECT` result set, i.e. it is subtraction of two result sets.

`EXCEPT` and `UNION` have the same operation precedence and `INTERSECT` has a higher precedence, unless running in Oracle mode, in which case all three have the same precedence.

Parentheses

Parentheses can be used to specify precedence.

ALL/DISTINCT

> **CURRENT**
>
> `EXCEPT ALL` and `EXCEPT DISTINCT` . The `ALL` operator leaves duplicates intact, while the `DISTINCT` operator removes duplicates. `DISTINCT` is the default behavior if neither operator is supplied.
>
> **< 10.5**
>
> Only `EXCEPT DISTINCT` is available.

Examples

Show customers which are not employees:

```
(SELECT e_name AS name, email FROM customers)
EXCEPT
(SELECT c_name AS name, email FROM employees);
```

Difference between UNION, EXCEPT and INTERSECT:

```
CREATE TABLE seqs (i INT);
INSERT INTO seqs VALUES (1),(2),(2),(3),(3),(4),(5),(6);

SELECT i FROM seqs WHERE i <= 3 UNION SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    1 |
|    2 |
|    3 |
|    4 |
|    5 |
|    6 |
+------+

SELECT i FROM seqs WHERE i <= 3 UNION ALL SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    1 |
|    2 |
|    2 |
|    3 |
|    3 |
|    3 |
|    3 |
|    4 |
|    5 |
|    6 |
+------+

SELECT i FROM seqs WHERE i <= 3 EXCEPT SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    1 |
|    2 |
+------+

SELECT i FROM seqs WHERE i <= 3 EXCEPT ALL SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    1 |
|    2 |
|    2 |
+------+

SELECT i FROM seqs WHERE i <= 3 INTERSECT SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    3 |
+------+

SELECT i FROM seqs WHERE i <= 3 INTERSECT ALL SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    3 |
|    3 |
+------+
```

Parentheses for specifying precedence:

```
CREATE OR REPLACE TABLE t1 (a INT);
CREATE OR REPLACE TABLE t2 (b INT);
CREATE OR REPLACE TABLE t3 (c INT);

INSERT INTO t1 VALUES (1),(2),(3),(4);
INSERT INTO t2 VALUES (5),(6);
INSERT INTO t3 VALUES (1),(6);

((SELECT a FROM t1) UNION (SELECT b FROM t2)) EXCEPT (SELECT c FROM t3);
+------+
| a    |
+------+
|    2 |
|    3 |
|    4 |
|    5 |
+------+

(SELECT a FROM t1) UNION ((SELECT b FROM t2) EXCEPT (SELECT c FROM t3));
+------+
| a    |
+------+
|    1 |
|    2 |
|    3 |
|    4 |
|    5 |
+------+
```

Here is an example that makes use of the SEQUENCE storage engine and the VALUES statement, to generate a numeric sequence and remove some arbitrary numbers from it:

```
(SELECT seq FROM seq_1_to_10) EXCEPT VALUES (2), (3), (4);
+-----+
| seq |
+-----+
|   1 |
|   5 |
|   6 |
|   7 |
|   8 |
|   9 |
|  10 |
+-----+
```

- INTERSECT
- Get Set for Set Theory: UNION, INTERSECT and EXCEPT in SQL (video tutorial)

This page is licensed: CC BY-SA / Gnu FDL

INTERSECT

Return only rows that appear in both result sets. This set operator identifies the common records shared between two queries.

Syntax

```
SELECT ...
(INTERSECT [ALL | DISTINCT] | EXCEPT [ALL | DISTINCT] | UNION [ALL | DISTINCT]) SELECT ...
[(INTERSECT [ALL | DISTINCT] | EXCEPT [ALL | DISTINCT] | UNION [ALL | DISTINCT]) SELECT ...]
[ORDER BY [column [, column ...]]]
[LIMIT {[offset,] row_count | row_count OFFSET offset}]
```

Description

MariaDB has supported `INTERSECT` (as well as EXCEPT) in addition to UNION since MariaDB 10.3.

All behavior for naming columns, `ORDER BY` and `LIMIT` is the same as for UNION.

`INTERSECT` implicitly supposes a `DISTINCT` operation.

The result of an intersect is the intersection of right and left `SELECT` results, i.e. only records that are present in both result sets will be included in the result of the operation.

`INTERSECT` has higher precedence than `UNION` and `EXCEPT` (unless running running in Oracle mode, in which case all three have the same precedence). If possible it will be executed linearly, but if not, it will be translated to a subquery in the `FROM` clause:

```
(SELECT a,b FROM t1)
UNION
(SELECT c,d FROM t2)
INTERSECT
(SELECT e,f FROM t3)
UNION
(SELECT 4,4);
```

will be translated to:

```
(SELECT a,b FROM t1)
UNION
SELECT c,d FROM
  ((SELECT c,d FROM t2)
   INTERSECT
   (SELECT e,f FROM t3)) dummy_subselect
UNION
(SELECT 4,4)
```

Parentheses

CURRENT

Parentheses can be used to specify precedence.

< 10.4

Parentheses **cannot** be used to specify precedence.

MariaDB starting with 10.5.0

ALL/DISTINCT

CURRENT

`INTERSECT ALL` and `INTERSECT DISTINCT` . The `ALL` operator leaves duplicates intact, while the `DISTINCT` operator removes duplicates. `DISTINCT` is the default behavior if neither operator is supplied.

< 10.5

> `DISTINCT` is the only behavior available.

Examples

Show customers which are employees:

```
(SELECT e_name AS name, email FROM employees)
INTERSECT
(SELECT c_name AS name, email FROM customers);
```

Difference between UNION, EXCEPT and `INTERSECT`:

```
CREATE TABLE seqs (i INT);
INSERT INTO seqs VALUES (1),(2),(2),(3),(3),(4),(5),(6);

SELECT i FROM seqs WHERE i <= 3 UNION SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    1 |
|    2 |
|    3 |
|    4 |
|    5 |
|    6 |
+------+

SELECT i FROM seqs WHERE i <= 3 UNION ALL SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    1 |
|    2 |
|    2 |
|    3 |
|    3 |
|    3 |
|    3 |
|    4 |
|    5 |
|    6 |
+------+

SELECT i FROM seqs WHERE i <= 3 EXCEPT SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    1 |
|    2 |
+------+

SELECT i FROM seqs WHERE i <= 3 EXCEPT ALL SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    1 |
|    2 |
|    2 |
+------+

SELECT i FROM seqs WHERE i <= 3 INTERSECT SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    3 |
+------+

SELECT i FROM seqs WHERE i <= 3 INTERSECT ALL SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    3 |
|    3 |
+------+
```

Parentheses for specifying precedence:

```
CREATE OR REPLACE TABLE t1 (a INT);
CREATE OR REPLACE TABLE t2 (b INT);
CREATE OR REPLACE TABLE t3 (c INT);

INSERT INTO t1 VALUES (1),(2),(3),(4);
INSERT INTO t2 VALUES (5),(6);
INSERT INTO t3 VALUES (1),(6);

((SELECT a FROM t1) UNION (SELECT b FROM t2)) INTERSECT (SELECT c FROM t3);
+------+
| a    |
+------+
|    1 |
|    6 |
+------+

(SELECT a FROM t1) UNION ((SELECT b FROM t2) INTERSECT (SELECT c FROM t3));
+------+
| a    |
+------+
|    1 |
|    2 |
|    3 |
|    4 |
|    6 |
+------+
```

MINUS

> **Note:**
>
> `MINUS` is available starting from MariaDB 10.6.1.

`MINUS` is a synonym for EXCEPT when SQL_MODE=ORACLE is set.

```
CREATE TABLE seqs (i INT);
INSERT INTO seqs VALUES (1),(2),(2),(3),(3),(4),(5),(6);

SET SQL_MODE='ORACLE';

SELECT i FROM seqs WHERE i <= 3 MINUS SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    1 |
|    2 |
+------+
```

This page is licensed: CC BY-SA / Gnu FDL

UNION

`UNION` is used to combine the results from multiple SELECT statements into a single result set.

Syntax

```
SELECT ...
UNION [ALL | DISTINCT] SELECT ...
[UNION [ALL | DISTINCT] SELECT ...]
[ORDER BY [column [, column ...]]]
[LIMIT {[offset,] row_count | row_count OFFSET offset}]
```

Description

`UNION` is used to combine the results from multiple SELECT statements into a single result set.

The column names from the first `SELECT` statement are used as the column names for the results returned. Selected columns listed in corresponding positions of each SELECT statement should have the same data type. (For example, the first column selected by the first statement should have the same type as the first column selected by the other statements.)

If they don't, the type and length of the columns in the result take into account the values returned by all of the SELECTs, so there is no need for explicit casting. Note that currently this is not the case for recursive CTEs - see MDEV-12325.

Table names can be specified as `db_name`.`tbl_name`. This permits writing `UNION`s which involve multiple databases. See Identifier Qualifiers for syntax details.

A UNION's global `ORDER BY` cannot reference an aggregate function. (Aggregate functions are allowed within the individual `SELECT` statements of a UNION.)

`EXCEPT` and `UNION` have the same operation precedence and `INTERSECT` has a higher precedence, unless running in Oracle mode, in which case all three have the same precedence.

ALL/DISTINCT

The `ALL` keyword causes duplicate rows to be preserved. The `DISTINCT` keyword (the default if the keyword is omitted) causes duplicate rows to be removed by the results.

`UNION ALL` and `UNION DISTINCT` can both be present in a query. In this case, `UNION` DISTINCT will override any `UNION ALL` to its left.

The server can in most cases execute `UNION ALL` without creating a temporary table (see MDEV-334).

ORDER BY and LIMIT

Individual `SELECT` statements can contain their own ORDER BY and LIMIT clauses. In this case, the individual queries need to be wrapped between parentheses. However, this does not affect the order of the UNION, so they only are useful to limit the record read by one `SELECT`.

The `UNION` can have global ORDER BY and LIMIT clauses, which affect the whole result set. If the columns retrieved by individual SELECT statements have an alias (AS), the `ORDER BY` must use that alias, not the real column names.

HIGH_PRIORITY

Specifying a query as HIGH_PRIORITY does not work inside a `UNION`. If applied to the first `SELECT`, it is ignored. Applying to a later `SELECT` results in a syntax error:

```
ERROR 1234 (42000): Incorrect usage/placement of 'HIGH_PRIORITY'
```

SELECT … INTO …

Individual `SELECT` statements cannot be written INTO DUMPFILE or INTO OUTFILE. If the last `SELECT` statement specifies `INTO DUMPFILE` or `INTO OUTFILE`, the entire result of the `UNION` will be written. Placing the clause after any other `SELECT` will result in a syntax error.

If the result is a single row, SELECT … INTO @var_name can also be used.

Parentheses

> **CURRENT**
>
> Parentheses can be used to specify precedence.
>
> **< 10.4**
>
> Parentheses **cannot** be used to specify precedence.

Examples

`UNION` between tables having different column names:

```
(SELECT e_name AS name, email FROM employees)
UNION
(SELECT c_name AS name, email FROM customers);
```

Specifying the `UNION` global order and limiting total rows:

```
(SELECT name, email FROM employees)
UNION
(SELECT name, email FROM customers)
ORDER BY name LIMIT 10;
```

Adding a constant row:

```
(SELECT 'John Doe' AS name, 'john.doe@example.net' AS email)
UNION
(SELECT name, email FROM customers);
```

Differing types:

```
SELECT CAST('x' AS CHAR(1)) UNION SELECT REPEAT('y',4);
+----------------------+
| CAST('x' AS CHAR(1)) |
+----------------------+
| x                    |
| yyyy                 |
+----------------------+
```

Returning the results in order of each individual `SELECT` by use of a sort column:

```
(SELECT 1 AS sort_column, e_name AS name, email FROM employees)
UNION
(SELECT 2, c_name AS name, email FROM customers) ORDER BY sort_column;
```

Difference between UNION, EXCEPT and INTERSECT:

```
CREATE TABLE seqs (i INT);
INSERT INTO seqs VALUES (1),(2),(2),(3),(3),(4),(5),(6);

SELECT i FROM seqs WHERE i <= 3 UNION SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    1 |
|    2 |
|    3 |
|    4 |
|    5 |
|    6 |
+------+

SELECT i FROM seqs WHERE i <= 3 UNION ALL SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    1 |
|    2 |
|    2 |
|    3 |
|    3 |
|    3 |
|    3 |
|    4 |
|    5 |
|    6 |
+------+

SELECT i FROM seqs WHERE i <= 3 EXCEPT SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    1 |
|    2 |
+------+

SELECT i FROM seqs WHERE i <= 3 EXCEPT ALL SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    1 |
|    2 |
|    2 |
+------+

SELECT i FROM seqs WHERE i <= 3 INTERSECT SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    3 |
+------+

SELECT i FROM seqs WHERE i <= 3 INTERSECT ALL SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    3 |
|    3 |
+------+
```

```
CREATE OR REPLACE TABLE t1 (a INT);
CREATE OR REPLACE TABLE t2 (b INT);
CREATE OR REPLACE TABLE t3 (c INT);

INSERT INTO t1 VALUES (1),(2),(3),(4);
INSERT INTO t2 VALUES (5),(6);
INSERT INTO t3 VALUES (1),(6);

((SELECT a FROM t1) UNION (SELECT b FROM t2)) INTERSECT (SELECT c FROM t3);
+------+
| a    |
+------+
|    1 |
|    6 |
+------+

(SELECT a FROM t1) UNION ((SELECT b FROM t2) INTERSECT (SELECT c FROM t3));
+------+
| a    |
+------+
|    1 |
|    2 |
|    3 |
|    4 |
|    6 |
+------+
```

Subqueries

See Subqueries With ALL.

Compare a value against all results from a subquery. The `ALL` operator returns `TRUE` if the comparison holds for every row returned by the subquery.

See Subqueries With ANY and SOME.

Compare a value against any result from a subquery. The `ANY` (or `SOME`) operator returns `TRUE` if the comparison holds for at least one row. `IN` can be used for `=ANY`.

See Subqueries With EXISTS.

Test for the existence of rows. The `EXISTS` operator returns `TRUE` if the subquery returns at least one row, often used for correlated subqueries.

See Subqueries With JOINs.

Understand when to use subqueries versus joins. This guide explains performance implications and how to rewrite subqueries as joins for efficiency.

See Subqueries in a FROM Clause (Derived Tables).

Use a subquery as a temporary table. Derived tables allow you to select from the result set of another query within the `FROM` clause.

See Row Subqueries.

Retrieve a single row of multiple values. A row subquery returns a tuple that can be compared against a row constructor in the outer query.

See Scalar Subqueries.

Return a single value. A scalar subquery produces a one-row, one-column result that can be used anywhere a constant or expression is valid.

See Subquery Limitations.

Review restrictions on subquery usage. This page details unsupported operations, such as modifying a table while selecting from it in a subquery.

This page is licensed: CC BY-SA / Gnu FDL

Subqueries With ALL

Subqueries and ALL

Subqueries using the ALL keyword will return `true` if the comparison returns `true` for each row returned by the subquery, or the subquery returns no rows.

Syntax

```
scalar_expression comparison_operator ALL <Table subquery>
```

- `scalar_expression` may be any expression that evaluates to a single value.
- `comparison_operator` may be any one of: `=`, `>`, `<`, `>=`, `<=`, `<>` or `!=`

`ALL` returns:

- `NULL` if the comparison operator returns `NULL` for at least one row returned by the Table subquery or scalar_expression returns `NULL`.
- `FALSE` if the comparison operator returns `FALSE` for at least one row returned by the Table subquery.
- `TRUE` if the comparison operator returns `TRUE` for all rows returned by the Table subquery, or if Table subquery returns no rows.

`NOT IN` is an alias for `<> ALL`.

Examples

```
CREATE TABLE sq1 (num TINYINT);

CREATE TABLE sq2 (num2 TINYINT);

INSERT INTO sq1 VALUES(100);

INSERT INTO sq2 VALUES(40),(50),(60);

SELECT * FROM sq1 WHERE num > ALL (SELECT * FROM sq2);
+------+
| num  |
+------+
|  100 |
+------+
```

Since `100` > all of `40`, `50` and `60`, the evaluation is true and the row is returned.

Adding a second row to sq1, where the evaluation for that record is false:

```
INSERT INTO sq1 VALUES(30);

SELECT * FROM sq1 WHERE num > ALL (SELECT * FROM sq2);
+------+
| num  |
+------+
|  100 |
+------+
```

Adding a new row to sq2, causing all evaluations to be false:

```
INSERT INTO sq2 VALUES(120);

SELECT * FROM sq1 WHERE num > ALL (SELECT * FROM sq2);
Empty set (0.00 sec)
```

When the subquery returns no results, the evaluation is still true:

```
SELECT * FROM sq1 WHERE num > ALL (SELECT * FROM sq2 WHERE num2 > 300);
+------+
| num  |
+------+
|  100 |
|   30 |
+------+
```

Evaluating against a NULL will cause the result to be unknown, or not true, and therefore return no rows:

```
INSERT INTO sq2 VALUES (NULL);

SELECT * FROM sq1 WHERE num > ALL (SELECT * FROM sq2);
```

This page is licensed: CC BY-SA / Gnu FDL

Subqueries With ANY and SOME

Syntax

`SOME` is a synonym for `ANY`.

```
scalar_expression comparison_operator ANY <Table subquery>
scalar_expression comparison_operator SOME <Table subquery>
```

- `scalar_expression` may be any expression that evaluates to a single value.
- `comparison_operator` may be any one of `=`, `>`, `<`, `>=`, `<=`, `<>` or `!=`.

> **Note:**
>
> **About IN**
>
> Although `IN` functions similarly to `= ANY`, it is documented separately due to unique optimization characteristics. Refer to Subqueries with IN and NOT IN for more details.

`ANY` or `SOME` returns:

- `TRUE` if the comparison operator returns `TRUE` for at least one row returned by the table subquery.
- `FALSE` if the comparison operator returns `FALSE` for all rows returned by the table subquery, or if the table subquery has no rows.
- `NULL` if the comparison operator returns `NULL` for at least one row returned by the table subquery and doesn't returns `TRUE` for any of them, or if `scalar_expression` returns `NULL`.

Examples

The subsequent examples use these tables:

```
CREATE TABLE sq1 (num1 TINYINT);
CREATE TABLE sq2 (num2 TINYINT);
INSERT INTO sq1 VALUES(100);
INSERT INTO sq2 VALUES(40),(50),(120);
```

Subquery With `ANY`

```
SELECT * FROM sq1 WHERE num1 > ANY (SELECT * FROM sq2);
+------+
| num1 |
+------+
|  100 |
+------+
```

`100` is greater than two of the three values, and so the expression evaluates to `true`.

Subquery With `SOME`

`SOME` is a synonym for `ANY`.

```
SELECT * FROM sq1 WHERE num1 > SOME (SELECT * FROM sq2);
+------+
| num1 |
+------+
|  100 |
+------+
```

`100` is greater than two of the three values, and so the expression evaluates to `true`.

Subqueries with IN and NOT IN

The `IN` operator tests whether a value is a member of a set of values returned by a subquery. It is the most commonly used construct for equality-based subquery comparisons in MariaDB.

While `IN` is logically related to the `ANY` and `SOME` operators, it has distinct semantics and receives specialized treatment from the query optimizer.

Syntax

```
scalar_expression [NOT] IN (subquery)
```

- `scalar_expression`: An expression that evaluates to a single value.
- `subquery`: A subquery that returns a single column.

Relationship to ANY and SOME

In MariaDB, `IN` is a synonym for `= ANY`.

- `IN` evaluates to `TRUE` if the comparison returns `TRUE` for at least one row produced by the subquery.

- `IN` evaluates to `FALSE` if the subquery returns no rows.

Despite this logical equivalence, the optimizer applies additional transformations to `IN` subqueries (such as semi-joins) that do not always apply to other quantitative `ANY` comparisons like `> ANY` or `<= SOME`.

Handling NULL Values

The behavior of `IN` and `NOT IN` follows SQL three-valued logic.

- Source Expression is NULL: If the `scalar_expression` is `NULL`, the result is `NULL`.
- Subquery Contains NULL (IN): If no match is found and the subquery contains at least one `NULL`, the result is `NULL`.
- Subquery Contains NULL (NOT IN): If the subquery returns any `NULL` value, `NOT IN` will always evaluate to `NULL` or `FALSE`, never `TRUE`, even if no matching non-null value exists.

> **Warning:**
>
> Avoid using `NOT IN` if the subquery columns can contain `NULL` values. In such cases, `NOT EXISTS` is generally safer and more predictable.

NOT IN vs. <> ANY

`NOT IN` and `<> ANY` are not synonyms and represent different logical tests:

OperatorText	Logical MeaningText	ResultText
`NOT IN`	“Is this value absent from the entire set?”	Returns `TRUE` only if the value matches no rows in the subquery.
`<> ANY`	“Is there at least one value in the set that is different?”	Returns `TRUE` if there is at least one row in the subquery that differs from the value.

Optimization and Performance

MariaDB treats `IN` subqueries as high-priority candidates for specific optimizations, including:

- Semi-join transformations: Converting the subquery into a join to improve execution speed.
- Subquery materialization: Storing the subquery result in a temporary internal table to avoid repeated execution.
- IN-to-EXISTS rewrites: Converting the predicate based on cost estimates.

Examples

The following examples use table `sq1` (values: `50`, `100`) and table `sq2` (values: `40`, `50`, `120`).

Using IN

```
SELECT * FROM sq1 WHERE num1 IN (SELECT num2 FROM sq2);
```

Result: `50` (Because `50` exists in both tables).

Using NOT IN

```
SELECT * FROM sq1 WHERE num1 NOT IN (SELECT num2 FROM sq2);
```

Result: `100` (Because `100` is not present in `sq2`).

NOT IN with NULL Pitfall

```
-- sq1 contains 50, 100
SELECT * FROM sq1 WHERE num1 NOT IN (SELECT NULL);
```

Result: Empty set (The condition evaluates to `NULL` for all rows, so no rows are returned).

This page is licensed: CC BY-SA / Gnu FDL

Subqueries With EXISTS

Subqueries and EXISTS

Syntax

```
SELECT ... WHERE EXISTS <Table subquery>
```

Description

Subqueries using the `EXISTS` keyword will return `true` if the subquery returns any rows. Conversely, subqueries using `NOT EXISTS` will return `true` only if the subquery returns no rows from the table.

EXISTS subqueries ignore the columns specified by the SELECT of the subquery, since they're not relevant. For example,

```
SELECT col1 FROM t1 WHERE EXISTS (SELECT * FROM t2);
```

and

```
SELECT col1 FROM t1 WHERE EXISTS (SELECT col2 FROM t2);
```

produce identical results.

Examples

```
CREATE TABLE sq1 (num TINYINT);

CREATE TABLE sq2 (num2 TINYINT);

INSERT INTO sq1 VALUES(100);

INSERT INTO sq2 VALUES(40),(50),(60);

SELECT * FROM sq1 WHERE EXISTS (SELECT * FROM sq2 WHERE num2>50);
+------+
| num  |
+------+
|  100 |
+------+

SELECT * FROM sq1 WHERE NOT EXISTS (SELECT * FROM sq2 GROUP BY num2 HAVING MIN(num2)=40);
Empty set (0.00 sec)
```

This page is licensed: CC BY-SA / Gnu FDL

Subqueries With JOINs

Subqueries and JOINs

A subquery can quite often, but not in all cases, be rewritten as a JOIN.

Rewriting Subqueries as JOINS

A subquery using `IN` can be rewritten with the `DISTINCT` keyword. Consider this query:

```
SELECT * FROM table1 WHERE col1 IN (SELECT col1 FROM table2);
```

It can be rewritten like this:

```
SELECT DISTINCT table1.* FROM table1, table2 WHERE table1.col1=table2.col1;
```

`NOT IN` or `NOT EXISTS` queries can also be rewritten. For example, these two queries return the same result when the compared columns contain no `NULL` values. They can differ when `NULL`s are present, because `NOT IN` evaluates to `UNKNOWN` against a `NULL`:

```
SELECT * FROM table1 WHERE col1 NOT IN (SELECT col1 FROM table2);
SELECT * FROM table1 WHERE NOT EXISTS (SELECT col1 FROM table2
         WHERE table1.col1=table2.col1);
```

They can both be rewritten like this:

```
SELECT table1.* FROM table1 LEFT JOIN table2 ON table1.col1=table2.col1
       WHERE table2.col1 IS NULL;
```

Subqueries that can be rewritten as a `LEFT JOIN` are sometimes more efficient.

Using Subqueries instead of JOINS

There are some scenarios, though, which call for subqueries rather than joins:

- When you want duplicates, but not false duplicates. Suppose `Table_1` has three rows — {`1`,`1`,`2`} — and `Table_2` has two rows — {`1`,`2`,`2`}. If you need to list the rows in `Table_1` which are also in `Table_2`, only this subquery-based `SELECT` statement will give the right answer (`1`,`1`,`2`):

```
SELECT Table_1.column_1
FROM   Table_1
WHERE  Table_1.column_1 IN
  (SELECT Table_2.column_1
    FROM   Table_2);
```

- This SQL statement won't work:

```
SELECT Table_1.column_1
FROM   Table_1,Table_2
WHERE  Table_1.column_1 = Table_2.column_1;
```

- because the result will be {`1`,`1`,`2`,`2`} — and the duplication of 2 is an error. This SQL statement won't work either:

```
SELECT DISTINCT Table_1.column_1
FROM   Table_1,Table_2
WHERE  Table_1.column_1 = Table_2.column_1;
```

- because the result will be {`1`,`2`} — and the removal of the duplicated 1 is an error too.
- When the outermost statement is not a query. The SQL statement:

```
UPDATE Table_1 SET column_1 = (SELECT column_1 FROM Table_2);
```

- can't be expressed using a join unless some rare SQL3 features are used.

- When the join is over an expression. The SQL statement:

```
SELECT * FROM Table_1
WHERE column_1 + 5 =
  (SELECT MAX(column_1) FROM Table_2);
```

- is hard to express with a join. In fact, the only way we can think of is this SQL statement:

```
SELECT Table_1.*
FROM   Table_1,
      (SELECT MAX(column_1) AS max_column_1 FROM Table_2) AS Table_2
WHERE  Table_1.column_1 + 5 = Table_2.max_column_1;
```

- which still involves a parenthesized query, so nothing is gained from the transformation.
- When you want to see the exception. For example, suppose the question is: Which books are longer than Das Kapital? These two queries are effectively almost the same:

```
SELECT DISTINCT Bookcolumn_1.*
FROM   Books AS Bookcolumn_1 JOIN Books AS Bookcolumn_2 USING(page_count)
WHERE  title = 'Das Kapital';

SELECT DISTINCT Bookcolumn_1.*
FROM   Books AS Bookcolumn_1
WHERE  Bookcolumn_1.page_count >
  (SELECT DISTINCT page_count
  FROM   Books AS Bookcolumn_2
  WHERE  title = 'Das Kapital');
```

- The difference is between these two SQL statements is, if there are two editions of Das Kapital (with different page counts), then the self-join example will return the books which are longer than the shortest edition of Das Kapital. That might be the wrong answer, since the original question didn't ask for "… longer than `ANY` book named Das Kapital" (it seems to contain a false assumption that there's only one edition).

This page is licensed: CC BY-SA / Gnu FDL

Subqueries in a FROM Clause (Derived Tables)

Although subqueries are more commonly placed in a WHERE clause, they can also form part of the FROM clause. Such subqueries are commonly called derived tables.

If a subquery is used in this way, you must also use an AS clause to name the result of the subquery.

ORACLE mode

MariaDB starting with 10.6.0

> **CURRENT**
>
> Anonymous subqueries in a FROM clause (no AS clause) are permitted in ORACLE mode.
>
> **< 10.6**
>
> Anonymous subqueries in a FROM clause (no `AS` clause) are **not** permitted in ORACLE mode.

Correlation Column List

MariaDB starting with 11.7.0

> **CURRENT**

> It is possible to assign column names in the derived table name syntax element.
>
> **< 11.7**
>
> It is **not** possible to assign column names in the derived table name syntax element.

Examples

```
CREATE TABLE student (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student VALUES
  ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
  ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
  ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
  ('Tatiana', 'SQL', 87), ('Tatiana', 'Tuning', 83);
```

Assume that, given the data above, you want to return the average total for all students. In other words, the average of Chun's 148 (75+73), Esben's 74 (43+31), etc.

You cannot do the following:

```
SELECT AVG(SUM(score)) FROM student GROUP BY name;
ERROR 1111 (HY000): Invalid use of group function
```

A subquery in the FROM clause is however permitted:

```
SELECT AVG(sq_sum) FROM (SELECT SUM(score) AS sq_sum FROM student GROUP BY name) AS t;
+-------------+
| AVG(sq_sum) |
+-------------+
|    134.0000 |
+-------------+
```

The following is permitted only in ORACLE mode, where a derived table may omit its alias:

```
SELECT * FROM (SELECT 1 FROM DUAL), (SELECT 2 FROM DUAL);
```

In this example, the second column of the derived table `dt` is used both within (`WHERE` c2 > 0), and outside, (`WHERE` a2 > 10), the specification. Both conditions apply to t1.c2.

```
CREATE OR REPLACE TABLE t1(c1 INT, c2 INT, c3 INT);

SELECT a1, a2 FROM (SELECT c1, c2, c3 FROM t1 WHERE c2 > 0) AS dt (a1, a2, a3) WHERE a2 > 10;
```

This page is licensed: CC BY-SA / Gnu FDL

Row Subqueries

A row subquery is a subquery returning a single row, as opposed to a scalar subquery, which returns a single column from a row, or a literal.

Examples

```
CREATE TABLE staff (name VARCHAR(10), age TINYINT);

CREATE TABLE customer (name VARCHAR(10), age TINYINT);

INSERT INTO staff VALUES ('Bilhah',37), ('Valerius',61), ('Maia',25);

INSERT INTO customer VALUES ('Thanasis',48), ('Valerius',61), ('Brion',51);

SELECT * FROM staff WHERE (name,age) = (SELECT name,age FROM customer WHERE name='Valerius');
+----------+------+
| name     | age  |
+----------+------+
| Valerius |   61 |
+----------+------+
```

Finding all rows in one table and also in another:

```
SELECT name,age FROM staff WHERE (name,age) IN (SELECT name,age FROM customer);
+----------+------+
| name     | age  |
+----------+------+
| Valerius |   61 |
+----------+------+
```

This page is licensed: CC BY-SA / Gnu FDL

Scalar Subqueries

A scalar subquery is a subquery that returns a single value. This is the simplest form of a subquery, and can be used in most places a literal or single column value is valid.

The data type, length and character set and collation are all taken from the result returned by the subquery. The result of a subquery can always be NULL, that is, no result returned. Even if the original value is defined as NOT NULL, this is disregarded.

A subquery cannot be used where only a literal is expected, for example LOAD DATA INFILE expects a literal string containing the file name, and LIMIT requires a literal integer.

Examples

```
CREATE TABLE sq1 (num TINYINT);

CREATE TABLE sq2 (num TINYINT);

INSERT INTO sq1 VALUES (1);

INSERT INTO sq2 VALUES (10* (SELECT num FROM sq1));

SELECT * FROM sq2;
+------+
| num  |
+------+
|   10 |
+------+
```

Inserting a second row means the subquery is no longer a scalar, and this particular query is not valid:

```
INSERT INTO sq1 VALUES (2);

INSERT INTO sq2 VALUES (10* (SELECT num FROM sq1));
ERROR 1242 (21000): Subquery returns more than 1 row
```

No rows in the subquery, so the scalar is NULL:

```
INSERT INTO sq2 VALUES (10* (SELECT num FROM sq3 WHERE num='3'));

SELECT * FROM sq2;
+------+
| num  |
+------+
|   10 |
| NULL |
+------+
```

A more traditional scalar subquery, as part of a `WHERE` clause:

```
SELECT * FROM sq1 WHERE num = (SELECT MAX(num)/10 FROM sq2);
+------+
| num  |
+------+
|    1 |
+------+
```

This page is licensed: CC BY-SA / Gnu FDL

Subquery Limitations

There are a number of limitations regarding subqueries, which are discussed below.

The following tables and data will be used in the examples that follow:

```
CREATE TABLE staff(name VARCHAR(10),age TINYINT);

CREATE TABLE customer(name VARCHAR(10),age TINYINT);
```

```
INSERT INTO staff VALUES
('Bilhah',37), ('Valerius',61), ('Maia',25);

INSERT INTO customer VALUES
('Thanasis',48), ('Valerius',61), ('Brion',51);
```

ORDER BY and LIMIT

LIMIT is not permitted in a subquery used with `IN`, `ALL`, `ANY`, or `SOME`. ORDER BY on its own is allowed. For example:

```
SELECT * FROM staff WHERE name IN (SELECT name FROM customer ORDER BY name);
+----------+------+
| name     | age  |
+----------+------+
| Valerius |   61 |
+----------+------+
```

is valid, but

```
SELECT * FROM staff WHERE name IN (SELECT NAME FROM customer ORDER BY name LIMIT 1);
ERROR 1235 (42000): This version of MariaDB doesn't
  yet support 'LIMIT & IN/ALL/ANY/SOME subquery'
```

is not.

Modifying and Selecting from the Same Table

It's not possible to both modify and select from the same table in a subquery. For example:

```
DELETE FROM staff WHERE name = (SELECT name FROM staff WHERE age=61);
ERROR 1093 (HY000): Table 'staff' is specified twice, both
  as a target for 'DELETE' and as a separate source for data
```

Row Comparison Operations

There is only partial support for row comparison operations. The expression in

```
expr op {ALL|ANY|SOME} subquery,
```

must be scalar and the subquery can only return a single column.

However, because of the way `IN` is implemented (it is rewritten as a sequence of `=` comparisons and `AND`), the expression in

```
expression [NOT] IN subquery
```

is permitted to be an n-tuple and the subquery can return rows of n-tuples.

For example:

```
SELECT * FROM staff WHERE (name,age) NOT IN (
  SELECT name,age FROM customer WHERE age >=51
);
+--------+------+
| name   | age  |
+--------+------+
| Bilhah |   37 |
| Maia   |   25 |
+--------+------+
```

is permitted, but

```
SELECT * FROM staff WHERE (name,age) = ALL (
  SELECT name,age FROM customer WHERE age >=51
);
ERROR 1241 (21000): Operand should contain 1 column(s)
```

is not.

Correlated Subqueries

Subqueries in the `FROM` clause cannot be correlated subqueries. They cannot be evaluated for each row of the outer query since they are evaluated to produce a result set during when the query is executed.

Stored Functions

A subquery can refer to a stored function which modifies data. This is an extension to the SQL standard, but can result in indeterminate outcomes. For example, take:

```
SELECT ... WHERE x IN (SELECT f() ...);
```

where *f()* inserts rows. The function *f()* could be executed a different number of times depending on how the optimizer chooses to handle the query.

This sort of construct is therefore not safe to use in replication that is not row-based, as there could be different results on the master and the slave.

Geometry Statements

See Geometry Constructors.

Learn about geometry constructors in MariaDB Server. This section details SQL functions for creating spatial data types like points, lines, and polygons, enabling geospatial data management.

See Geometry Properties.

Learn about geometry properties. This section details SQL functions for retrieving attributes of spatial objects, such as area, length, and bounding box, essential for geospatial analysis.

See Geometry Relations.

Learn about geometry relations in MariaDB Server. This section details SQL functions for determining spatial relationships between geometric objects, such as ST_Intersects and ST_Contains.

See LineString Properties.

Learn about LINESTRING properties in MariaDB Server. This section details SQL functions for retrieving attributes of linear spatial objects, such as length, number of points, and start/end points.

See MBR (Minimum Bounding Rectangle).

Learn about Minimum Bounding Rectangles (MBR) in MariaDB Server. This section details how to calculate and use MBRs for spatial indexing and efficient querying of geometric data.

See Miscellaneous GIS functions.

Explore miscellaneous GIS functions in MariaDB Server. This section details various SQL functions that support geographic information system operations and spatial data analysis.

See Point Properties.

Learn about POINT properties in MariaDB Server. This section details SQL functions for retrieving attributes of point spatial objects, such as their X and Y coordinates.

See Polygon Properties.

Learn about POLYGON properties in MariaDB Server. This section details SQL functions for retrieving attributes of polygonal spatial objects, such as area, perimeter, and the number of rings.

See WKB.

Learn about Well-Known Binary (WKB) in MariaDB Server. This section details how to represent and store geometric data in a binary format, essential for efficient spatial data exchange and storage.

See WKT.

Learn about Well-Known Text (WKT) in MariaDB Server. This section details how to represent and store geometric data in a text format, essential for human-readable spatial data exchange.

BUFFER

A synonym for ST_BUFFER.

This page is licensed: CC BY-SA / Gnu FDL

CONVEXHULL

A synonym for ST_CONVEXHULL.

This page is licensed: CC BY-SA / Gnu FDL

GEOMETRYCOLLECTION

Syntax

```
GeometryCollection(g1,g2,...)
```

Description

Constructs a WKB GeometryCollection. If any argument is not a well-formed WKB representation of a geometry, the return value is `NULL`.

Examples

```
CREATE TABLE gis_geometrycollection  (g GEOMETRYCOLLECTION);
SHOW FIELDS FROM gis_geometrycollection;
INSERT INTO gis_geometrycollection VALUES
    (GeomCollFromText('GEOMETRYCOLLECTION(POINT(0 0), LINESTRING(0 0,10 10))')),
    (GeometryFromWKB(AsWKB(GeometryCollection(Point(44, 6), LineString(Point(3, 6), Point(7, 9))))),
    (GeomFromText('GeometryCollection()')),
    (GeomFromText('GeometryCollection EMPTY'));
```

```
CREATE TABLE geomcoll_example (
  g GEOMETRYCOLLECTION
);
```

```
INSERT INTO geomcoll_example VALUES
  (ST_GeomCollFromText(
    'GEOMETRYCOLLECTION(POINT(0 0), LINESTRING(0 1, 0 2),
    POINT(1 0))')),
  (GeometryCollection(
    Point(0, 0),
    LineString(Point(0, 1), Point(0, 2))));
```

```
SELECT ST_AsWKT(g) FROM geomcoll_example;

+-------------------------------------------------------------+
| ST_AsWKT(g)                                                 |
+-------------------------------------------------------------+
| GEOMETRYCOLLECTION(POINT(0 0),LINESTRING(0 1,0 2),POINT(1 0)) |
| GEOMETRYCOLLECTION(POINT(0 0),LINESTRING(0 1,0 2))          |
+-------------------------------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

LINESTRING

Syntax

```
LineString(pt1,pt2,...)
```

Description

WKB LineString from WKB Point coordinate data.
Constructs a WKB LineString value from a number of WKB Point arguments. If any argument is not a WKB Point, the return value is `NULL`. If the number of Point arguments is less than two, the return value is `NULL`.

Examples

```
SET @ls = 'LineString(1 1,2 2,3 3)';

SELECT AsText(EndPoint(GeomFromText(@ls)));
+-------------------------------------+
| AsText(EndPoint(GeomFromText(@ls))) |
+-------------------------------------+
| POINT(3 3)                          |
+-------------------------------------+

CREATE TABLE gis_line  (g LINESTRING);
INSERT INTO gis_line VALUES
    (LineFromText('LINESTRING(0 0,0 10,10 0)')),
    (LineStringFromText('LINESTRING(10 10,20 10,20 20,10 20,10 10)')),
    (LineStringFromWKB(AsWKB(LineString(Point(10, 10), Point(40, 10)))));
```

Linestring_Example:

```
CREATE TABLE linestring_example (
  g LINESTRING
);
```

```
INSERT INTO linestring_example VALUES
  (ST_LineFromText('LINESTRING(0 0, 1 1, 2 2)')),
  (ST_LineStringFromText('LINESTRING(10 10, 20 10, 20 20, 10 20, 10 10)')),
  (LineString(Point(10, 10), Point(40, 10)));
```

```
SELECT ST_AsWKT(g) FROM linestring_example;
<</code>>

<<sql>>
+-----------------------------------------+
| ST_AsWKT(g)                             |
+-----------------------------------------+
| LINESTRING(0 0,1 1,2 2)                 |
| LINESTRING(10 10,20 10,20 20,10 20,10 10) |
| LINESTRING(10 10,40 10)                 |
+-----------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

MULTILINESTRING

Syntax

```
MultiLineString(ls1,ls2,...)
```

Description

Constructs a WKB MultiLineString value using WKB LineString arguments. If any argument is not a WKB LineString, the return value is `NULL`.

Example

```
CREATE TABLE gis_multi_line (g MULTILINESTRING);
INSERT INTO gis_multi_line VALUES
 (MultiLineStringFromText('MULTILINESTRING((10 48,10 21,10 0),(16 0,16 23,16 48))')),
 (MLineFromText('MULTILINESTRING((10 48,10 21,10 0))')),
 (MLineFromWKB(AsWKB(MultiLineString(LineString(Point(1, 2),
    Point(3, 5)), LineString(Point(2, 5),Point(5, 8),Point(21, 7))))));
```

MultiLineString_Example:

```
CREATE TABLE mlstr_example (
  m MULTILINESTRING
);
```

```
INSERT INTO mlstr_example VALUES
  (ST_MultiLineStringFromText(
    'MULTILINESTRING((0 40, 0 20, 6 30, 12 20, 12 40),
    (15 40, 15 20, 25 20, 30 25, 30 35, 25 40, 15 40))')),
  (ST_MLineFromText('MULTILINESTRING((0 0, 1 1, 2 2))')),
  (MultiLineString(
    LineString(Point(0, 40), Point(0, 20)),
    LineString(Point(6, 30), Point(12, 20), Point(12, 40))));
```

```
INSERT INTO mlstr_example VALUES
  (MultiLineStringFromText(
    'MULTILINESTRING((0 40, 0 20, 6 30, 12 20, 12 40),
    (15 40, 15 20, 25 20, 30 25, 30 35, 25 40, 15 40))')),
  (MLineFromText('MULTILINESTRING((0 0, 1 1, 2 2))')),
  (MultiLineString(
    LineString(Point(0, 40), Point(0, 20)),
    LineString(Point(6, 30), Point(12, 20), Point(12, 40))));
```

```
SELECT ST_AsWKT(m) FROM mlstr_example;
```

```
+-----------------------------------------------------------------------------------------------+
| ST_AsWKT(m)                                                                                   |
+-----------------------------------------------------------------------------------------------+
| MULTILINESTRING((0 40,0 20,6 30,12 20,12 40),(15 40,15 20,25 20,30 25,30 35,25 40,15 40)) |
| MULTILINESTRING((0 0,1 1,2 2))                                                                |
| MULTILINESTRING((0 40,0 20),(6 30,12 20,12 40))                                               |
+-----------------------------------------------------------------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

MULTIPOINT

Syntax

```
MultiPoint(pt1,pt2,...)
```

Description

Constructs a WKB MultiPoint value using WKB Point arguments. If any argument is not a WKB Point, the return value is `NULL`.

Examples

```
SET @g = ST_GEOMFROMTEXT('MultiPoint( 1 1, 2 2, 5 3, 7 2, 9 3, 8 4, 6 6, 6 9, 4 9, 1 5 )');

CREATE TABLE gis_multi_point (g MULTIPOINT);
INSERT INTO gis_multi_point VALUES
    (MultiPointFromText('MULTIPOINT(0 0,10 10,10 20,20 20)')),
    (MPointFromText('MULTIPOINT(1 1,11 11,11 21,21 21)')),
    (MPointFromWKB(AsWKB(MultiPoint(Point(3, 6), Point(4, 10)))));
```

MultiPoint_Example:

```
CREATE TABLE multipoint_example (
  m MULTIPOINT
);
```

```
INSERT INTO multipoint_example VALUES
  (ST_MultiPointFromText('MULTIPOINT(0 0, 1 0, 1 1, 0 1)')),
  (ST_MPointFromText('MULTIPOINT(1 1, 2 2, 3 3, 4 4)')),
  (MultiPoint(Point(0, 0), Point(1, 1)));
```

```
INSERT INTO multipoint_example VALUES
  (MultiPointFromText('MULTIPOINT(0 0, 1 0, 1 1, 0 1)')),
  (MPointFromText('MULTIPOINT(1 1, 2 2, 3 3, 4 4)')),
  (MultiPoint(Point(0, 0), Point(1, 1)));
```

```
SELECT ST_AsWKT(m) FROM multipoint_example;
```

```
+----------------------------+
| ST_AsWKT(m)                |
+----------------------------+
| MULTIPOINT(0 0,1 0,1 1,0 1) |
| MULTIPOINT(1 1,2 2,3 3,4 4) |
| MULTIPOINT(0 0,1 1)         |
+----------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

MULTIPOLYGON

Syntax

```
MultiPolygon(poly1,poly2,...)
```

Description

Constructs a WKB MultiPolygon value from a set of WKB Polygon arguments. If any argument is not a WKB Polygon, the return value is `NULL`.

Example

```
CREATE TABLE gis_multi_polygon  (g MULTIPOLYGON);
INSERT INTO gis_multi_polygon VALUES
    (MultiPolygonFromText('MULTIPOLYGON(((28 26,28 0,84 0,84 42,28 26),(52 18,66 23,73 9,48 6,52 18)),
     ((59 18,67 18,67 13,59 13,59 18)))')),
    (MPolyFromText('MULTIPOLYGON(((28 26,28 0,84 0,84 42,28 26),(52 18,66 23,73 9,48 6,52 18)),
        ((59 18,67 18,67 13,59 13,59 18)))')),
    (MPolyFromWKB(AsWKB(MultiPolygon(Polygon(LineString(
       Point(0, 3), Point(3, 3), Point(3, 0), Point(0, 3)))))));
```

MultiPolygon_Example:

```
CREATE TABLE multipolygon_example (
  m MULTIPOLYGON
);
```

```
INSERT INTO multipolygon_example VALUES
  (ST_MultiPolygonFromText(
    'MULTIPOLYGON(((0 40, 0 20, 6 30, 12 20, 12 40, 0 40),
    (15 40, 15 20, 25 20, 30 25, 30 35, 25 40, 15 40)))')),
  (ST_MPolyFromText(
    'MULTIPOLYGON(((-5 45, 35 45, 35 15, -5 15, -5 45),
    (0 40, 0 20, 6 30, 12 20, 12 40, 0 40),
    (15 40, 15 20, 25 20, 30 25, 30 35, 25 40, 15 40)))')),
  (MultiPolygon(Polygon(LineString(Point(0, 0), Point(0, 1),
     Point(1, 1), Point(1, 0), Point(0, 0)))));
```

```
SELECT ST_AsWKT(m) FROM multipolygon_example;
```

```
+-----------------------------------------------------------------------------------------------------------
----------------------+
| ST_AsWKT(m)
|
+-----------------------------------------------------------------------------------------------------------
----------------------+
| MULTIPOLYGON(((0 40,0 20,6 30,12 20,12 40,0 40),(15 40,15 20,25 20,30 25,30 35,25 40,15 40)))
|
| MULTIPOLYGON(((-5 45,35 45,35 15,-5 15,-5 45),(0 40,0 20,6 30,12 20,12 40,0 40),(15 40,15 20,25 20,30
25,30 35,25 40,15 40))) |
| MULTIPOLYGON(((0 0,0 1,1 1,1 0,0 0)))
|
+-----------------------------------------------------------------------------------------------------------
----------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

POINT

Syntax

```
Point(x,y)
```

Description

Constructs a WKB Point using the given coordinates.

Examples

```
SET @g = ST_GEOMFROMTEXT('Point(1 1)');

CREATE TABLE gis_point  (g POINT);
INSERT INTO gis_point VALUES
    (PointFromText('POINT(10 10)')),
    (PointFromText('POINT(20 10)')),
    (PointFromText('POINT(20 20)')),
    (PointFromWKB(AsWKB(PointFromText('POINT(10 20)'))));
```

Point_Example:

```
CREATE TABLE point_example (
  p POINT
);
```

```
INSERT INTO point_example VALUES
  (ST_PointFromText('POINT(1 1)')),
  (ST_PointFromText('POINT(2 2)')),
  (Point(3, 3)),
  (Point(4, 4));
```

```
SELECT ST_AsWKT(p) FROM point_example;
```

```
+-------------+
| ST_AsWKT(p) |
+-------------+
| POINT(1 1)  |
| POINT(2 2)  |
| POINT(3 3)  |
| POINT(4 4)  |
+-------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

PointOnSurface

A synonym for ST_PointOnSurface.

This page is licensed: CC BY-SA / Gnu FDL

POLYGON

Syntax

```
Polygon(ls1,ls2,...)
```

Description

Constructs a WKB Polygon value from a number of WKB LineString arguments. If any argument does not represent the WKB of a LinearRing (that is, not a closed and simple LineString) the return value is `NULL`.

Note that according to the OpenGIS standard, a POLYGON should have exactly one ExteriorRing and all other rings should lie within that ExteriorRing and thus be the InteriorRings. Practically, however, some systems, including MariaDB's, permit polygons to have several 'ExteriorRings'. In the case of there being multiple, non-overlapping exterior rings ST_NUMINTERIORRINGS() will return 1.

Examples

```
SET @g = ST_GEOMFROMTEXT('POLYGON((1 1,1 5,4 9,6 9,9 3,7 2,1 1))');

CREATE TABLE gis_polygon   (g POLYGON);
INSERT INTO gis_polygon VALUES
    (PolygonFromText('POLYGON((10 10,20 10,20 20,10 20,10 10))')),
    (PolyFromText('POLYGON((0 0,50 0,50 50,0 50,0 0), (10 10,20 10,20 20,10 20,10 10))')),
    (PolyFromWKB(AsWKB(Polygon(LineString(Point(0, 0), Point(30, 0), Point(30, 30), Point(0, 0))))));
```

Non-overlapping 'polygon':

```
SELECT ST_NumInteriorRings(ST_PolyFromText('POLYGON((0 0,10 0,10 10,0 10,0 0),
  (-1 -1,-5 -1,-5 -5,-1 -5,-1 -1))')) AS NumInteriorRings;
+------------------+
| NumInteriorRings |
+------------------+
|                1 |
+------------------+
```

Polygon_Example:

```
CREATE TABLE polygon_example (
  p POLYGON
);
```

```
INSERT INTO polygon_example VALUES
  (ST_PolygonFromText('POLYGON((0 40, 0 20, 6 30, 12 20, 12 40, 0 40))')),
  (ST_PolyFromText('POLYGON((15 40, 15 20, 25 20, 30 25, 30 35, 25 40, 15 40))')),
  (Polygon(LineString(Point(0, 0), Point(0, 1), Point(1, 1),
  Point(1, 0), Point(0, 0))));
```

```
SELECT ST_AsWKT(p) FROM polygon_example;
```

```
+-----------------------------------------------------+
| ST_AsWKT(p)                                         |
+-----------------------------------------------------+
| POLYGON((0 40,0 20,6 30,12 20,12 40,0 40))          |
| POLYGON((15 40,15 20,25 20,30 25,30 35,25 40,15 40)) |
| POLYGON((0 0,0 1,1 1,1 0,0 0))                      |
+-----------------------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ST_BUFFER

Syntax

```
ST_BUFFER(g1,r)
BUFFER(g1,r)
```

Description

Returns a geometry that represents all points whose distance from geometry `g1` is less than or equal to distance, or radius, `r`.

Uses for this function could include creating for example a new geometry representing a buffer zone around an island.

BUFFER() is a synonym.

Examples

Determining whether a point is within a buffer zone:

```
SET @g1 = ST_GEOMFROMTEXT('POLYGON((10 10, 10 20, 20 20, 20 10, 10 10))');

SET @g2 = ST_GEOMFROMTEXT('POINT(8 8)');

SELECT ST_WITHIN(@g2,ST_BUFFER(@g1,5));
+--------------------------------+
| ST_WITHIN(@g2,ST_BUFFER(@g1,5)) |
+--------------------------------+
|                              1 |
+--------------------------------+

SELECT ST_WITHIN(@g2,ST_BUFFER(@g1,1));
+--------------------------------+
| ST_WITHIN(@g2,ST_BUFFER(@g1,1)) |
+--------------------------------+
|                              0 |
+--------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

ST_CONVEXHULL

Syntax

```
ST_ConvexHull(g)
ConvexHull(g)
```

Description

Given a geometry, returns a geometry that is the minimum convex geometry enclosing all geometries within the set. Returns NULL if the geometry value is NULL or an empty value.

ST_ConvexHull() and ConvexHull() are synonyms.

Examples

The ConvexHull of a single point is simply the single point:

```
SET @g = ST_GEOMFROMTEXT('Point(0 0)');

SELECT ST_ASTEXT(ST_CONVEXHULL(@g));
+-----------------------------+
| ST_ASTEXT(ST_CONVEXHULL(@g)) |
+-----------------------------+
| POINT(0 0)                  |
+-----------------------------+
```

```
SET @g = ST_GEOMFROMTEXT('MultiPoint(0 0, 1 2, 2 3)');

SELECT ST_ASTEXT(ST_CONVEXHULL(@g));
+-----------------------------+
| ST_ASTEXT(ST_CONVEXHULL(@g)) |
+-----------------------------+
| POLYGON((0 0,1 2,2 3,0 0))   |
+-----------------------------+
```

```
SET @g = ST_GEOMFROMTEXT('MultiPoint( 1 1, 2 2, 5 3, 7 2, 9 3, 8 4, 6 6, 6 9, 4 9, 1 5 )');

SELECT ST_ASTEXT(ST_CONVEXHULL(@g));
+---------------------------------------+
| ST_ASTEXT(ST_CONVEXHULL(@g))          |
+---------------------------------------+
| POLYGON((1 1,1 5,4 9,6 9,9 3,7 2,1 1)) |
+---------------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

ST_INTERSECTION

Syntax

```
ST_INTERSECTION(g1,g2)
```

Description

Returns a geometry that is the intersection, or shared portion, of geometry `g1` and geometry `g2`.

Examples

```
SET @g1 = ST_GEOMFROMTEXT('POINT(2 1)');

SET @g2 = ST_GEOMFROMTEXT('LINESTRING(2 1, 0 2)');

SELECT ASTEXT(ST_INTERSECTION(@g1,@g2));
+---------------------------------+
| ASTEXT(ST_INTERSECTION(@g1,@g2)) |
+---------------------------------+
| POINT(2 1)                      |
+---------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

ST_POINTONSURFACE

Syntax

```
ST_PointOnSurface(g)
PointOnSurface(g)
```

Description

Given a geometry, returns a POINT guaranteed to intersect a surface. However, see MDEV-7514.

ST_PointOnSurface() and PointOnSurface() are synonyms.

This page is licensed: CC BY-SA / Gnu FDL

ST_SYMDIFFERENCE

Syntax

```
ST_SYMDIFFERENCE(g1,g2)
```

Description

Returns a geometry that represents the portions of geometry `g1` and geometry `g2` that don't intersect.

Examples

```
SET @g1 = ST_GEOMFROMTEXT('LINESTRING(10 20, 10 40)');

SET @g2 = ST_GEOMFROMTEXT('LINESTRING(10 15, 10 25)');

SELECT ASTEXT(ST_SYMDIFFERENCE(@g1,@g2));
+--------------------------------------------+
| ASTEXT(ST_SYMDIFFERENCE(@g1,@g2))          |
+--------------------------------------------+
| MULTILINESTRING((10 15,10 20),(10 25,10 40)) |
+--------------------------------------------+

SET @g2 = ST_GeomFromText('LINESTRING(10 20, 10 41)');

SELECT ASTEXT(ST_SYMDIFFERENCE(@g1,@g2));
+-----------------------------------+
| ASTEXT(ST_SYMDIFFERENCE(@g1,@g2)) |
+-----------------------------------+
| LINESTRING(10 40,10 41)           |
+-----------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

ST_UNION

Syntax

```
ST_UNION(g1,g2)
```

Description

Returns a geometry that is the union of the geometry `g1` and geometry `g2`.

Examples

```
SET @g1 = GEOMFROMTEXT('POINT (0 2)');

SET @g2 = GEOMFROMTEXT('POINT (2 0)');

SELECT ASTEXT(ST_UNION(@g1,@g2));
+---------------------------+
| ASTEXT(ST_UNION(@g1,@g2)) |
+---------------------------+
| MULTIPOINT(2 0,0 2)       |
+---------------------------+
```

```
SET @g1 = GEOMFROMTEXT('POLYGON((0 0,0 3,3 3,3 0,0 0))');

SET @g2 = GEOMFROMTEXT('POLYGON((2 2,4 2,4 4,2 4,2 2))');

SELECT ASTEXT(ST_UNION(@g1,@g2));
+---------------------------------------------+
| ASTEXT(ST_UNION(@g1,@g2))                   |
+---------------------------------------------+
| POLYGON((0 0,0 3,2 3,2 4,4 4,4 2,3 2,3 0,0 0)) |
+---------------------------------------------+
```

ST_AsGeoJSON

Syntax

```
ST_AsGeoJSON(g[, max_decimals[, options]])
```

Description

Returns the given geometry *g* as a GeoJSON element. The optional *max_decimals* limits the maximum number of decimals displayed.

The optional *options* flag can be set to `1` to add a bounding box to the output.

Examples

```
SELECT ST_AsGeoJSON(ST_GeomFromText('POINT(5.3 7.2)'));
+-------------------------------------------------+
| ST_AsGeoJSON(ST_GeomFromText('POINT(5.3 7.2)')) |
+-------------------------------------------------+
| {"type": "Point", "coordinates": [5.3, 7.2]}    |
+-------------------------------------------------+
```

See Also

ST_GeomFromGeoJSON

Syntax

```
ST_GeomFromGeoJSON(g[, option])
```

Description

Given a GeoJSON input *g*, returns a geometry object. The *option* specifies what to do if *g* contains geometries with coordinate dimensions higher than 2.

Option	Description
1	Return an error (the default)
2 - 4	The document is accepted, but the coordinates for higher coordinate dimensions are stripped off.

Examples

```
SET @j = '{ "type": "Point", "coordinates": [5.3, 15.0]}';

SELECT ST_AsText(ST_GeomFromGeoJSON(@j));
+-----------------------------------+
| ST_AsText(ST_GeomFromGeoJSON(@j)) |
+-----------------------------------+
| POINT(5.3 15)                     |
+-----------------------------------+
```

BOUNDARY

A synonym for ST_BOUNDARY.

This page is licensed: CC BY-SA / Gnu FDL

DIMENSION

A synonym for ST_DIMENSION.

This page is licensed: CC BY-SA / Gnu FDL

ENVELOPE

A synonym for ST_ENVELOPE.

This page is licensed: CC BY-SA / Gnu FDL

GeometryN

A synonym for ST_GeometryN.

This page is licensed: CC BY-SA / Gnu FDL

GeometryType

A synonym for ST_GeometryType.

This page is licensed: CC BY-SA / Gnu FDL

IsClosed

A synonym for ST_IsClosed.

This page is licensed: CC BY-SA / Gnu FDL

IsEmpty

A synonym for ST_IsEmpty.

This page is licensed: CC BY-SA / Gnu FDL

IsRing

A synonym for ST_IsRing.

This page is licensed: CC BY-SA / Gnu FDL

IsSimple

A synonym for ST_IsSImple.

This page is licensed: CC BY-SA / Gnu FDL

NumGeometries

A synonym for ST_NumGeometries.

This page is licensed: CC BY-SA / Gnu FDL

SRID

A synonym for ST_SRID.

This page is licensed: CC BY-SA / Gnu FDL

ST_BOUNDARY

Syntax

```
ST_BOUNDARY(g)
BOUNDARY(g)
```

Description

Returns a geometry that is the closure of the combinatorial boundary of the geometry value `g`.

BOUNDARY() is a synonym.

Examples

```
SELECT ST_AsText(ST_Boundary(ST_GeomFromText('LINESTRING(3 3,0 0, -3 3)')));
+---------------------------------------------------------------------+
| ST_AsText(ST_Boundary(ST_GeomFromText('LINESTRING(3 3,0 0, -3 3)'))) |
+---------------------------------------------------------------------+
| MULTIPOINT(3 3,-3 3)                                                |
+---------------------------------------------------------------------+

SELECT ST_AsText(ST_Boundary(ST_GeomFromText('POLYGON((3 3,0 0, -3 3, 3 3))')));
+------------------------------------------------------------------------+
| ST_AsText(ST_Boundary(ST_GeomFromText('POLYGON((3 3,0 0, -3 3, 3 3))'))) |
+------------------------------------------------------------------------+
| LINESTRING(3 3,0 0,-3 3,3 3)                                           |
+------------------------------------------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ST_DIMENSION

Syntax

```
ST_Dimension(g)
Dimension(g)
```

Description

Returns the inherent dimension of the geometry value `g`. The result can be

Dimension	Definition
-1	empty geometry
0	geometry with no length or area
1	geometry with no area but nonzero length
2	geometry with nonzero area

`ST_Dimension()` and `Dimension()` are synonyms.

Examples

```
SELECT Dimension(GeomFromText('LineString(1 1,2 2)'));
+-----------------------------------------------+
| Dimension(GeomFromText('LineString(1 1,2 2)')) |
+-----------------------------------------------+
|                                             1 |
+-----------------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ST_ENVELOPE

Syntax

```
ST_ENVELOPE(g)
ENVELOPE(g)
```

Description

Returns the Minimum Bounding Rectangle (MBR) for the geometry value `g`. The result is returned as a Polygon value.

The polygon is defined by the corner points of the bounding box:

```
POLYGON((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

`ST_ENVELOPE()` and `ENVELOPE()` are synonyms.

Examples

```
SELECT AsText(ST_ENVELOPE(GeomFromText('LineString(1 1,4 4)')));
+-----------------------------------------------------------+
| AsText(ST_ENVELOPE(GeomFromText('LineString(1 1,4 4)'))) |
+-----------------------------------------------------------+
| POLYGON((1 1,4 1,4 4,1 4,1 1))                            |
+-----------------------------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ST_GEOMETRYN

Syntax

```
ST_GeometryN(gc,N)
GeometryN(gc,N)
```

Description

Returns the N-th geometry in the GeometryCollection *gc*. Geometries are numbered beginning with 1.

`ST_GeometryN()` and `GeometryN()` are synonyms.

Example

```
SET @gc = 'GeometryCollection(Point(1 1),LineString(12 14, 9 11))';

SELECT AsText(GeometryN(GeomFromText(@gc),1));
+--------------------------------------+
| AsText(GeometryN(GeomFromText(@gc),1)) |
+--------------------------------------+
| POINT(1 1)                           |
+--------------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

ST_GEOMETRYTYPE

Syntax

```
ST_GeometryType(g)
GeometryType(g)
```

Description

Returns as a string the name of the geometry type of which the geometry instance `g` is a member. The name corresponds to one of the instantiable Geometry subclasses.

`ST_GeometryType()` and `GeometryType()` are synonyms.

Examples

```
SELECT GeometryType(GeomFromText('POINT(1 1)'));
+---------------------------------------+
| GeometryType(GeomFromText('POINT(1 1)')) |
+---------------------------------------+
| POINT                                 |
+---------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ST_ISCLOSED

Syntax

```
ST_IsClosed(g)
IsClosed(g)
```

Description

Returns 1 if a given LINESTRING's start and end points are the same, or 0 if they are not the same.

`ST_IsClosed()` and `IsClosed()` are synonyms.

Examples

```
SET @ls = 'LineString(0 0, 0 4, 4 4, 0 0)';
SELECT ST_ISCLOSED(GEOMFROMTEXT(@ls));
+--------------------------------+
| ST_ISCLOSED(GEOMFROMTEXT(@ls)) |
+--------------------------------+
|                              1 |
+--------------------------------+

SET @ls = 'LineString(0 0, 0 4, 4 4, 0 1)';
SELECT ST_ISCLOSED(GEOMFROMTEXT(@ls));
+--------------------------------+
| ST_ISCLOSED(GEOMFROMTEXT(@ls)) |
+--------------------------------+
|                              0 |
+--------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

ST_ISEMPTY

Syntax

```
ST_IsEmpty(g)
IsEmpty(g)
```

Description

IsEmpty is a function defined by the OpenGIS specification, but is not fully implemented by MariaDB or MySQL.

Since MariaDB and MySQL do not support GIS EMPTY values such as POINT EMPTY, as implemented it simply returns `1` if the geometry value *`g`* is invalid, `0` if it is valid, and `NULL` if the argument is `NULL`.

`ST_IsEmpty()` and `IsEmpty()` are synonyms.

This page is licensed: GPLv2, originally from fill_help_tables.sql

ST_IsRing

Syntax

```
ST_IsRing(g)
IsRing(g)
```

Description

Returns true if a given LINESTRING is a ring, that is, both ST_IsClosed and ST_IsSimple. A simple curve does not pass through the same point more than once. However, see MDEV-7510.

`St_IsRing()` and `IsRing()` are synonyms.

This page is licensed: CC BY-SA / Gnu FDL

ST_IsSimple

Syntax

```
ST_IsSimple(g)
IsSimple(g)
```

Description

Returns true if the given Geometry has no anomalous geometric points, false if it does, or NULL if given a NULL value.

ST_IsSimple() and IsSimple() are synonyms.

Examples

A POINT is always simple.

```
SET @g = 'Point(1 2)';

SELECT ST_ISSIMPLE(GEOMFROMTEXT(@g));
+------------------------------+
| ST_ISSIMPLE(GEOMFROMTEXT(@g)) |
+------------------------------+
|                            1 |
+------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

ST_NUMGEOMETRIES

Syntax

```
ST_NumGeometries(gc)
NumGeometries(gc)
```

Description

Returns the number of geometries in the GeometryCollection `gc`.

`ST_NumGeometries()` and `NumGeometries()` are synonyms.

Example

```
SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';

SELECT NUMGEOMETRIES(GeomFromText(@gc));
+----------------------------------+
| NUMGEOMETRIES(GeomFromText(@gc)) |
+----------------------------------+
|                                2 |
+----------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

ST_RELATE

Syntax

```
ST_Relate(g1, g2, i)
```

Description

Returns true if Geometry `g1` is spatially related to Geometry `g2` by testing for intersections between the interior, boundary and exterior of the two geometries as specified by the values in intersection matrix pattern `i`.

This page is licensed: CC BY-SA / Gnu FDL

ST_SRID

Syntax

```
ST_SRID(g)
SRID(g)
```

Description

Returns an integer indicating the Spatial Reference System ID for the geometry value g.

In MariaDB, the SRID value is just an integer associated with the geometry value. All calculations are done assuming Euclidean (planar) geometry.

`ST_SRID()` and `SRID()` are synonyms.

Examples

```
SELECT SRID(GeomFromText('LineString(1 1,2 2)',101));
+---------------------------------------------+
| SRID(GeomFromText('LineString(1 1,2 2)',101)) |
+---------------------------------------------+
|                                         101 |
+---------------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

- ST_LENGTH
- ST_OVERLAPS
- ST_TOUCHES
- ST_WITHIN
- TOUCHES
- WITHIN

This page is licensed: CC BY-SA / Gnu FDL

CONTAINS

Syntax

```
Contains(g1,g2)
```

Description

Returns `1` or `0` to indicate whether a geometry `g1` completely contains geometry `g2`. CONTAINS() is based on the original MySQL implementation and uses object bounding rectangles, while ST_CONTAINS() uses object shapes.

This tests the opposite relationship to Within().

This page is licensed: GPLv2, originally from fill_help_tables.sql

CROSSES

Syntax

```
Crosses(g1,g2)
```

Description

Returns `1` if `g1` spatially crosses `g2`. Returns `NULL` if `g1` is a Polygon or a MultiPolygon, or if `g2` is a Point or a MultiPoint. Otherwise, returns `0`.

The term spatially crosses denotes a spatial relation between two given geometries that has the following properties:

- The two geometries intersect.
- Their intersection results in a geometry that has a dimension that is one less than the maximum dimension of the two given geometries.
- Their intersection is not equal to either of the two given geometries.

`CROSSES()` is based on the original MySQL implementation, and uses object bounding rectangles, while ST_CROSSES() uses object shapes.

This page is licensed: GPLv2, originally from fill_help_tables.sql

DISJOINT

Syntax

```
Disjoint(g1,g2)
```

Description

Returns `1` or `0` to indicate whether `g1` is spatially disjoint from (does not intersect) `g2`.

`DISJOINT()` tests the opposite relationship to INTERSECTS().

`DISJOINT()` is based on the original MySQL implementation and uses object bounding rectangles, while ST_DISJOINT() uses object shapes.

This page is licensed: GPLv2, originally from fill_help_tables.sql

EQUALS

Syntax

```
MBREQUALS(g1,g2)
```

Description

Returns `1` or `0` to indicate whether *`g1`* is spatially equal to *`g2`*.

EQUALS() is based on the original MySQL implementation and uses object bounding rectangles, while ST_EQUALS() uses object shapes.

`MBREQUALS` is a synonym for `Equals`.

This page is licensed: GPLv2, originally from fill_help_tables.sql

INTERSECTS

Syntax

```
INTERSECTS(g1,g2)
```

Description

Returns `1` or `0` to indicate whether geometry *`g1`* spatially intersects geometry *`g2`*.

INTERSECTS() is based on the original MySQL implementation and uses object bounding rectangles, while ST_INTERSECTS() uses object shapes.

`INTERSECTS()` tests the opposite relationship to DISJOINT().

This page is licensed: GPLv2, originally from fill_help_tables.sql

OVERLAPS

Syntax

```
OVERLAPS(g1,g2)
```

Description

Returns `1` or `0` to indicate whether `g1` spatially overlaps `g2`.
The term spatially overlaps is used if two geometries of equal dimensions intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

`OVERLAPS()` is based on the original MySQL implementation and uses object bounding rectangles, while ST_OVERLAPS() uses object shapes.

This page is licensed: GPLv2, originally from fill_help_tables.sql

ST_CONTAINS

Syntax

```
ST_CONTAINS(g1,g2)
```

Description

Returns `1` or `0` to indicate whether a geometry `g1` completely contains geometry `g2`.

ST_CONTAINS() uses object shapes, while CONTAINS(), based on the original MySQL implementation, uses object bounding rectangles.

ST_CONTAINS tests the opposite relationship to ST_WITHIN().

Examples

```
SET @g1 = ST_GEOMFROMTEXT('POLYGON((175 150, 20 40, 50 60, 125 100, 175 150))');

SET @g2 = ST_GEOMFROMTEXT('POINT(174 149)');

SELECT ST_CONTAINS(@g1,@g2);
+----------------------+
| ST_CONTAINS(@g1,@g2) |
+----------------------+
|                    1 |
+----------------------+

SET @g2 = ST_GEOMFROMTEXT('POINT(175 151)');

SELECT ST_CONTAINS(@g1,@g2);
+----------------------+
| ST_CONTAINS(@g1,@g2) |
+----------------------+
|                    0 |
+----------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

ST_CROSSES

Syntax

```
ST_CROSSES(g1,g2)
```

Description

Returns `1` if geometry *`g1`* spatially crosses geometry *`g2`*. Returns `NULL` if `g1` is a Polygon or a MultiPolygon, or if `g2` is a Point or a MultiPoint. Otherwise, returns `0`.

The term spatially crosses denotes a spatial relation between two given geometries that has the following properties:

- The two geometries intersect.
- Their intersection results in a geometry that has a dimension that is one less than the maximum dimension of the two given geometries.
- Their intersection is not equal to either of the two given geometries.

`ST_CROSSES()` uses object shapes, while CROSSES(), based on the original MySQL implementation, uses object bounding rectangles.

Examples

```
SET @g1 = ST_GEOMFROMTEXT('LINESTRING(174 149, 176 151)');

SET @g2 = ST_GEOMFROMTEXT('POLYGON((175 150, 20 40, 50 60, 125 100, 175 150))');

SELECT ST_CROSSES(@g1,@g2);
+---------------------+
| ST_CROSSES(@g1,@g2) |
+---------------------+
|                   1 |
+---------------------+

SET @g1 = ST_GEOMFROMTEXT('LINESTRING(176 149, 176 151)');

SELECT ST_CROSSES(@g1,@g2);
+---------------------+
| ST_CROSSES(@g1,@g2) |
+---------------------+
|                   0 |
+---------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

ST_DIFFERENCE

Syntax

```
ST_DIFFERENCE(g1,g2)
```

Description

Returns a geometry representing the point set difference of the given geometry values.

Example

```
SET @g1 = POINT(10,10), @g2 = POINT(20,20);

SELECT ST_AsText(ST_Difference(@g1, @g2));
+-----------------------------------+
| ST_AsText(ST_Difference(@g1, @g2)) |
+-----------------------------------+
| POINT(10 10)                      |
+-----------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

ST_DISJOINT

Syntax

```
ST_DISJOINT(g1,g2)
```

Description

Returns `1` or `0` to indicate whether geometry *`g1`* is spatially disjoint from (does not intersect with) geometry *`g2`*.

`ST_DISJOINT()` uses object shapes, while DISJOINT(), based on the original MySQL implementation, uses object bounding rectangles.

`ST_DISJOINT()` tests the opposite relationship to ST_INTERSECTS().

Examples

```
SET @g1 = ST_GEOMFROMTEXT('POINT(0 0)');

SET @g2 = ST_GEOMFROMTEXT('LINESTRING(2 0, 0 2)');

SELECT ST_DISJOINT(@g1,@g2);
+----------------------+
| ST_DISJOINT(@g1,@g2) |
+----------------------+
|                    1 |
+----------------------+

SET @g2 = ST_GEOMFROMTEXT('LINESTRING(0 0, 0 2)');

SELECT ST_DISJOINT(@g1,@g2);
+----------------------+
| ST_DISJOINT(@g1,@g2) |
+----------------------+
|                    0 |
+----------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

ST_DISTANCE

Syntax

```
ST_DISTANCE(g1,g2)
```

Description

Returns the distance between two geometries, or null if not given valid inputs.

Example

```
SELECT ST_Distance(POINT(1,2),POINT(2,2));
+-----------------------------------+
| ST_Distance(POINT(1,2),POINT(2,2)) |
+-----------------------------------+
|                                 1 |
+-----------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

ST_DISTANCE_SPHERE

Syntax

```
ST_DISTANCE_SPHERE(g1,g2,[r])
```

Description

Returns the spherical distance in meters between two geometries (point or multipoint) on a sphere. The optional radius *r* is in meters, must be positive, and defaults to the Earth's radius (6370986 meters) if not specified. If either of the two geometries are not valid, `NULL` is returned.

Example

```
SET @zenica   = ST_GeomFromText('POINT(17.907743 44.203438)');
SET @sarajevo = ST_GeomFromText('POINT(18.413076 43.856258)');
SELECT ST_Distance_Sphere(@zenica, @sarajevo);
+--------------------------------------+
| ST_Distance_Sphere(@zenica, @sarajevo) |
+--------------------------------------+
|                     55878.59337591705 |
+--------------------------------------+

SELECT ST_Distance_Sphere(@zenica, @sarajevo, 6370986);
+------------------------------------------------+
| ST_Distance_Sphere(@zenica, @sarajevo, 6370986) |
+------------------------------------------------+
|                              55878.59337591705 |
+------------------------------------------------+

SELECT ST_Distance_Sphere(@zenica, @sarajevo, 200);
+-------------------------------------------+
| ST_Distance_Sphere(@zenica, @sarajevo, 200) |
+-------------------------------------------+
|                          1.754158410516584 |
+-------------------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

ST_EQUALS

Syntax

```
ST_EQUALS(g1,g2)
```

Description

Returns `1` or `0` to indicate whether geometry *`g1`* is spatially equal to geometry *`g2`*.

`ST_EQUALS()` uses object shapes, while EQUALS(), based on the original MySQL implementation, uses object bounding rectangles.

Examples

```
SET @g1 = ST_GEOMFROMTEXT('LINESTRING(174 149, 176 151)');

SET @g2 = ST_GEOMFROMTEXT('LINESTRING(176 151, 174 149)');

SELECT ST_EQUALS(@g1,@g2);
+--------------------+
| ST_EQUALS(@g1,@g2) |
+--------------------+
|                  1 |
+--------------------+
```

```
SET @g1 = ST_GEOMFROMTEXT('POINT(0 2)');

SET @g1 = ST_GEOMFROMTEXT('POINT(2 0)');

SELECT ST_EQUALS(@g1,@g2);
+--------------------+
| ST_EQUALS(@g1,@g2) |
+--------------------+
|                  0 |
+--------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

ST_INTERSECTS

Syntax

```
ST_INTERSECTS(g1,g2)
```

Description

Returns `1` or `0` to indicate whether geometry *`g1`* spatially intersects geometry *`g2`*.

`ST_INTERSECTS()` uses object shapes, while INTERSECTS(), based on the original MySQL implementation, uses object bounding rectangles.

`ST_INTERSECTS()` tests the opposite relationship to ST_DISJOINT().

Examples

```
SET @g1 = ST_GEOMFROMTEXT('POINT(0 0)');

SET @g2 = ST_GEOMFROMTEXT('LINESTRING(0 0, 0 2)');

SELECT ST_INTERSECTS(@g1,@g2);
+------------------------+
| ST_INTERSECTS(@g1,@g2) |
+------------------------+
|                      1 |
+------------------------+
```

```
SET @g2 = ST_GEOMFROMTEXT('LINESTRING(2 0, 0 2)');

SELECT ST_INTERSECTS(@g1,@g2);
+------------------------+
| ST_INTERSECTS(@g1,@g2) |
+------------------------+
|                      0 |
+------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

ST_LENGTH

Syntax

```
ST_LENGTH(ls)
```

Description

Returns as a double-precision number the length of the LineString value *`ls`* in its associated spatial reference.

Examples

```
SET @ls = 'LineString(1 1,2 2,3 3)';

SELECT ST_LENGTH(ST_GeomFromText(@ls));
+---------------------------------+
| ST_LENGTH(ST_GeomFromText(@ls)) |
+---------------------------------+
|               2.82842712474619 |
+---------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

ST_OVERLAPS

Syntax

```
ST_OVERLAPS(g1,g2)
```

Description

Returns `1` or `0` to indicate whether geometry *`g1`* spatially overlaps geometry *`g2`*.

The term spatially overlaps is used if two geometries of equal dimensions intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

`ST_OVERLAPS()` uses object shapes, while OVERLAPS(), based on the original MySQL implementation, uses object bounding rectangles.

This page is licensed: CC BY-SA / Gnu FDL

ST_TOUCHES

Syntax

```
ST_TOUCHES(g1,g2)
```

Description

Returns `1` or `0` to indicate whether geometry *`g1`* spatially touches geometry *`g2`*. Two geometries spatially touch if the interiors of the geometries do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

ST_TOUCHES() uses object shapes, while TOUCHES(), based on the original MySQL implementation, uses object bounding rectangles.

Examples

```
SET @g1 = ST_GEOMFROMTEXT('POINT(2 0)');

SET @g2 = ST_GEOMFROMTEXT('LINESTRING(2 0, 0 2)');

SELECT ST_TOUCHES(@g1,@g2);
+---------------------+
| ST_TOUCHES(@g1,@g2) |
+---------------------+
|                   1 |
+---------------------+

SET @g1 = ST_GEOMFROMTEXT('POINT(2 1)');

SELECT ST_TOUCHES(@g1,@g2);
+---------------------+
| ST_TOUCHES(@g1,@g2) |
+---------------------+
|                   0 |
+---------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

ST_WITHIN

Syntax

```
ST_WITHIN(g1,g2)
```

Description

Returns `1` or `0` to indicate whether geometry *`g1`* is spatially within geometry *`g2`*.

This tests the opposite relationship as ST_CONTAINS().

`ST_WITHIN()` uses object shapes, while WITHIN(), based on the original MySQL implementation, uses object bounding rectangles.

Examples

```
SET @g1 = ST_GEOMFROMTEXT('POINT(174 149)');

SET @g2 = ST_GEOMFROMTEXT('POLYGON((175 150, 20 40, 50 60, 125 100, 175 150))');

SELECT ST_WITHIN(@g1,@g2);
+--------------------+
| ST_WITHIN(@g1,@g2) |
+--------------------+
|                  1 |
+--------------------+

SET @g1 = ST_GEOMFROMTEXT('POINT(176 151)');

SELECT ST_WITHIN(@g1,@g2);
+--------------------+
| ST_WITHIN(@g1,@g2) |
+--------------------+
|                  0 |
+--------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

TOUCHES

Syntax

```
Touches(g1,g2)
```

Description

Returns `1` or `0` to indicate whether `g1` spatially touches `g2`. Two geometries spatially touch if the interiors of the geometries do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

`TOUCHES()` is based on the original MySQL implementation and uses object bounding rectangles, while ST_TOUCHES() uses object shapes.

This page is licensed: GPLv2, originally from fill_help_tables.sql

WITHIN

Syntax

```
Within(g1,g2)
```

Description

Returns `1` or `0` to indicate whether `g1` is spatially within `g2`. This tests the opposite relationship as Contains().

`WITHIN()` is based on the original MySQL implementation, and uses object bounding rectangles, while ST_WITHIN() uses object shapes.

Examples

```
SET @g1 = GEOMFROMTEXT('POINT(174 149)');
SET @g2 = GEOMFROMTEXT('POINT(176 151)');
SET @g3 = GEOMFROMTEXT('POLYGON((175 150, 20 40, 50 60, 125 100, 175 150))');

SELECT within(@g1,@g3);
+------------------+
| within(@g1,@g3) |
+------------------+
|               1 |
+------------------+

SELECT within(@g2,@g3);
+------------------+
| within(@g2,@g3) |
+------------------+
|               0 |
+------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

LineString Properties

See ENDPOINT.

Synonym for ST_ENDPOINT. Returns the last point of a LineString geometry.

See GLENGTH.

Synonym for ST_LENGTH. Calculates the length of a LineString or MultiLineString in its associated spatial reference units.

See NumPoints.

Synonym for ST_NUMPOINTS. Returns the number of points in a LineString geometry.

See PointN.

Synonym for ST_POINTN. Returns the N-th point in a LineString geometry, where N is a 1-based index.

See STARTPOINT.

Synonym for ST_STARTPOINT. Returns the first point of a LineString geometry.

See ST_ENDPOINT.

Returns the end Point of a LineString. This function retrieves the final coordinate in the linear geometry sequence.

See ST_NUMPOINTS.

Returns the count of Points in a LineString. This function calculates the total number of vertices defining the line.

See ST_POINTN.

Returns the N-th Point in a LineString. This function retrieves a specific point from the sequence based on its 1-based index.

See ST_STARTPOINT.

Returns the start Point of a LineString. This function retrieves the initial coordinate in the linear geometry sequence.

This page is licensed: CC BY-SA / Gnu FDL

ENDPOINT

A synonym for ST_ENDPOINT.

This page is licensed: CC BY-SA / Gnu FDL

GLENGTH

Syntax

```
GLength(ls)
```

Description

Returns as a double-precision number the length of the LineString value `ls` in its associated spatial reference.

Examples

```
SET @ls = 'LineString(1 1,2 2,3 3)';

SELECT GLength(GeomFromText(@ls));
+---------------------------+
| GLength(GeomFromText(@ls)) |
+---------------------------+
|           2.82842712474619 |
+---------------------------+
```

See Also

- ST_LENGTH() is the OpenGIS equivalent.

This page is licensed: GPLv2, originally from fill_help_tables.sql

NumPoints

A synonym for ST_NumPoints.

This page is licensed: CC BY-SA / Gnu FDL

PointN

A synonym for ST_PointN.

This page is licensed: CC BY-SA / Gnu FDL

STARTPOINT

A synonym for ST_STARTPOINT.

This page is licensed: CC BY-SA / Gnu FDL

ST_ENDPOINT

Syntax

```
ST_EndPoint(ls)
EndPoint(ls)
```

Description

Returns the Point that is the endpoint of the LineString value `ls`.

`ST_EndPoint()` and `EndPoint()` are synonyms.

Examples

```
SET @ls = 'LineString(1 1,2 2,3 3)';

SELECT AsText(EndPoint(GeomFromText(@ls)));
+-------------------------------------+
| AsText(EndPoint(GeomFromText(@ls))) |
+-------------------------------------+
| POINT(3 3)                          |
+-------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ST_NUMPOINTS

Syntax

```
ST_NumPoints(ls)
NumPoints(ls)
```

Description

Returns the number of Point objects in the LineString value `ls`.

`ST_NumPoints()` and `NumPoints()` are synonyms.

Examples

```
SET @ls = 'LineString(1 1,2 2,3 3)';

SELECT NumPoints(GeomFromText(@ls));
+------------------------------+
| NumPoints(GeomFromText(@ls)) |
+------------------------------+
|                            3 |
+------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ST_POINTN

Syntax

```
ST_PointN(ls,N)
PointN(ls,N)
```

Description

Returns the N-th Point in the LineString value `ls`. Points are numbered beginning with `1`.

`ST_PointN()` and `PointN()` are synonyms.

Examples

```
SET @ls = 'LineString(1 1,2 2,3 3)';

SELECT AsText(PointN(GeomFromText(@ls),2));
+-------------------------------------+
| AsText(PointN(GeomFromText(@ls),2)) |
+-------------------------------------+
| POINT(2 2)                          |
+-------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ST_STARTPOINT

Syntax

```
ST_StartPoint(ls)
StartPoint(ls)
```

Description

Returns the Point that is the start point of the LineString value `ls`.

`ST_StartPoint()` and `StartPoint()` are synonyms.

Examples

```
SET @ls = 'LineString(1 1,2 2,3 3)';

SELECT AsText(StartPoint(GeomFromText(@ls)));
+--------------------------------------+
| AsText(StartPoint(GeomFromText(@ls))) |
+--------------------------------------+
| POINT(1 1)                           |
+--------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

MBR (Minimum Bounding Rectangle)

See MBR Definition.

Understand Minimum Bounding Rectangles. An MBR is the smallest rectangle that completely encloses a geometry, defined by its minimum and maximum X and Y coordinates.

See MBRContains.

Check if one MBR contains another. Returns 1 if the Minimum Bounding Rectangle of the first geometry completely encloses the MBR of the second geometry.

See MBRCoveredBy.

Check if one MBR is covered by another. Returns 1 if the MBR of the first geometry is entirely contained within the MBR of the second geometry.

See MBRDisjoint.

Check if two MBRs are disjoint. Returns 1 if the Minimum Bounding Rectangles of the two geometries do not intersect or touch at all.

See MBREqual.

Check if two MBRs are identical. Returns 1 if the Minimum Bounding Rectangles of both geometries share the exact same coordinates.

See MBRIntersects.

Check if two MBRs intersect. Returns 1 if the Minimum Bounding Rectangles of the geometries share any portion of space, including boundaries.

See MBROverlaps.

Check if two MBRs overlap. Returns 1 if the MBRs intersect but neither completely contains the other, and they have the same dimension.

See MBRTouches.

Check if two MBRs touch. Returns 1 if the MBRs intersect only at their boundaries and do not share any interior points.

See MBRWithin.

Check if one MBR is within another. Returns 1 if the MBR of the first geometry is completely enclosed by the MBR of the second geometry.

This page is licensed: CC BY-SA / Gnu FDL

MBR Definition

Description

The MBR (Minimum Bounding Rectangle), or Envelope is the bounding geometry, formed by the minimum and maximum (X,Y) coordinates:

Examples

```
((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

MBRContains

Syntax

```
MBRContains(g1,g2)
```

Description

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangle of g1 contains the Minimum Bounding Rectangle of g2. This tests the opposite relationship as MBRWithin().

Examples

```
SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');

SET @g2 = GeomFromText('Point(1 1)');

SELECT MBRContains(@g1,@g2), MBRContains(@g2,@g1);
+----------------------+----------------------+
| MBRContains(@g1,@g2) | MBRContains(@g2,@g1) |
+----------------------+----------------------+
|                    1 |                    0 |
+----------------------+----------------------+
```

See Also

- MBRWithin

This page is licensed: GPLv2, originally from fill_help_tables.sql

MBRCoveredBy

> **Note:**
>
> MBRCoveredBy is available from MariaDB 12.0.

Syntax

```
MBRCoveredBy(g1, g2)
```

Description

Returns 1 if the minimum bounding rectangle of `g1` is covered by the minimum bounding rectangle of `g2`, otherwise 0.

Returns `NULL` If any argument is `NULL`, or an argument is an empty geometry.

Examples

```
SET @g1a = ST_GeomFromText('Point(5 6)');
SET @g1b = ST_GeomFromText('Point(5 11)');
SET @g2 = ST_GeomFromText('Polygon((0 0,0 10,10 10,10 0,0 0))');

SELECT MBRCoveredby(@g1a,@g2), MBRCoveredby(@g1b,@g2);
+------------------------+------------------------+
| MBRCoveredby(@g1a,@g2) | MBRCoveredby(@g1b,@g2) |
+------------------------+------------------------+
|                      1 |                      0 |
+------------------------+------------------------+
```

See Also

This page is licensed: CC BY-SA / Gnu FDL

MBRDisjoint

Syntax

```
MBRDisjoint(g1,g2)
```

Description

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries g1 and g2 are disjoint. Two geometries are disjoint if they do not intersect, that is touch or overlap.

Examples

```
SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
SET @g2 = GeomFromText('Polygon((4 4,4 7,7 7,7 4,4 4))');
SELECTmbrdisjoint(@g1,@g2);
+----------------------+
| mbrdisjoint(@g1,@g2) |
+----------------------+
|                    1 |
+----------------------+

SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
SET @g2 = GeomFromText('Polygon((3 3,3 6,6 6,6 3,3 3))');
SELECT mbrdisjoint(@g1,@g2);
+----------------------+
| mbrdisjoint(@g1,@g2) |
+----------------------+
|                    0 |
+----------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

MBREqual

Syntax

```
MBREqual(g1,g2)
MBREquals(g1,g2)
```

Description

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries g1 and g2 are the same.

`MBREquals` is a synonym.

Examples

```
SET @g1=GEOMFROMTEXT('LINESTRING(0 0, 1 2)');
SET @g2=GEOMFROMTEXT('POLYGON((0 0, 0 2, 1 2, 1 0, 0 0))');
SELECT MbrEqual(@g1,@g2);
+------------------+
| MbrEqual(@g1,@g2) |
+------------------+
|                1 |
+------------------+

SET @g1=GEOMFROMTEXT('LINESTRING(0 0, 1 3)');
SET @g2=GEOMFROMTEXT('POLYGON((0 0, 0 2, 1 4, 1 0, 0 0))');
SELECT MbrEqual(@g1,@g2);
+------------------+
| MbrEqual(@g1,@g2) |
+------------------+
|                0 |
+------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

MBRIntersects

Syntax

```
MBRIntersects(g1,g2)
```

Description

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries g1 and g2 intersect.

Examples

```
SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
SET @g2 = GeomFromText('Polygon((3 3,3 6,6 6,6 3,3 3))');
SELECT mbrintersects(@g1,@g2);
+------------------------+
| mbrintersects(@g1,@g2) |
+------------------------+
|                      1 |
+------------------------+

SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
SET @g2 = GeomFromText('Polygon((4 4,4 7,7 7,7 4,4 4))');
SELECT mbrintersects(@g1,@g2);
+------------------------+
| mbrintersects(@g1,@g2) |
+------------------------+
|                      0 |
+------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

MBROverlaps

Syntax

```
MBROverlaps(g1,g2)
```

Description

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries `g1` and `g2` overlap. The term spatially overlaps is used if two geometries intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

Examples

```
SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
SET @g2 = GeomFromText('Polygon((4 4,4 7,7 7,7 4,4 4))');
SELECT mbroverlaps(@g1,@g2);
+----------------------+
| mbroverlaps(@g1,@g2) |
+----------------------+
|                    0 |
+----------------------+

SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
SET @g2 = GeomFromText('Polygon((3 3,3 6,6 6,6 3,3 3))');
SELECT mbroverlaps(@g1,@g2);
+----------------------+
| mbroverlaps(@g1,@g2) |
+----------------------+
|                    0 |
+----------------------+

SET @g1 = GeomFromText('Polygon((0 0,0 4,4 4,4 0,0 0))');
SET @g2 = GeomFromText('Polygon((3 3,3 6,6 6,6 3,3 3))');
SELECT mbroverlaps(@g1,@g2);
+----------------------+
| mbroverlaps(@g1,@g2) |
+----------------------+
|                    1 |
+----------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

MBRTouches

Syntax

```
MBRTouches(g1,g2)
```

Description

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries `g1` and `g2` touch. Two geometries spatially touch if the interiors of the geometries do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

Examples

```
SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
SET @g2 = GeomFromText('Polygon((4 4,4 7,7 7,7 4,4 4))');
SELECT mbrtouches(@g1,@g2);
+---------------------+
| mbrtouches(@g1,@g2) |
+---------------------+
|                   0 |
+---------------------+

SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
SET @g2 = GeomFromText('Polygon((3 3,3 6,6 6,6 3,3 3))');
SELECT mbrtouches(@g1,@g2);
+---------------------+
| mbrtouches(@g1,@g2) |
+---------------------+
|                   1 |
+---------------------+

SET @g1 = GeomFromText('Polygon((0 0,0 4,4 4,4 0,0 0))');
SET @g2 = GeomFromText('Polygon((3 3,3 6,6 6,6 3,3 3))');
SELECT mbrtouches(@g1,@g2);
+---------------------+
| mbrtouches(@g1,@g2) |
+---------------------+
|                   0 |
+---------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

MBRWithin

Syntax

```
MBRWithin(g1,g2)
```

Description

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangle of g1 is within the Minimum Bounding Rectangle of g2. This tests the opposite relationship as MBRContains().

Examples

```
SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
SET @g2 = GeomFromText('Polygon((0 0,0 5,5 5,5 0,0 0))');
SELECT MBRWithin(@g1,@g2), MBRWithin(@g2,@g1);
+--------------------+--------------------+
| MBRWithin(@g1,@g2) | MBRWithin(@g2,@g1) |
+--------------------+--------------------+
|                  1 |                  0 |
+--------------------+--------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

Miscellaneous GIS functions

See ST_Collect.

Aggregate multiple geometries into a collection. This function creates a MultiPoint, MultiLineString, MultiPolygon, or GeometryCollection from a set of geometry arguments.

See ST_GeoHash.

Generate a Geohash string from a point or coordinates. This function encodes spatial locations into short, alphanumeric strings for efficient indexing and proximity searches.

See ST_IsValid.

Check if a geometry is valid. This function returns 1 if the geometry complies with OGC specifications (e.g., no self-intersections), 0 otherwise.

See ST_LatFromGeoHash.

Decode a Geohash to retrieve the latitude. This function returns the latitude coordinate (Y-axis) from a given Geohash string.

See ST_LongFromGeoHash.

Decode a Geohash to retrieve the longitude. This function returns the longitude coordinate (X-axis) from a given Geohash string.

See ST_PointFromGeoHash.

Create a Point geometry from a Geohash. This function decodes a Geohash string into a Point object representing the location's center.

See ST_Simplify.

Simplify a geometry using the Douglas-Peucker algorithm. This function reduces the number of vertices in a geometry while preserving its general shape, useful for rendering maps.

See ST_Validate.

Validate and optionally return a geometry. This function checks if a geometry is valid according to OGC rules; it returns the geometry if valid, or NULL if not.

This page is licensed: CC BY-SA / Gnu FDL

ST_Collect

> **Note:**
>
> ST_Collect is available from MariaDB 12.0.

Syntax

```
ST_Collect(g)
```

Description

ST_Collect is an aggregate function that can also be used as a window function.

Given multiple geometries, returns the aggregation of the distinct geometry arguments. This function also supports the DISTINCT option. If DISTINCT is used, it returns the aggregation of the distinct geometry arguments.

The resulting value type is chosen using the following policy:

- If all arguments are Point values, the result is a MultiPoint value.
- If all arguments are LineString values, the result is a MultiLineString value.
- If all arguments are Polygon values, the result is a MultiPolygon value.
- Otherwise, the result is a GeometryCollection value.

If there are multiple geometry arguments and those arguments are in the same spatial reference system (SRS), the return value is in that SRS. If those arguments are not in the same SRS, an

`ER_GIS_DIFFERENT_SRIDS_AGGREGATION` error occurs.

Examples

Multiple Point geometries aggregated into a MultiPoint geometry:

```
CREATE OR REPLACE TABLE t1 ( running_number INTEGER NOT NULL
  AUTO_INCREMENT, grouping_condition INTEGER, location GEOMETRY , PRIMARY KEY (
  running_number));

INSERT INTO t1 ( grouping_condition, location ) VALUES
  ( 0,ST_GEOMFROMTEXT('POINT(0 0)',4326)),
  ( 1,ST_GEOMFROMTEXT('POINT(0 0)',4326)),
  ( 0,ST_GEOMFROMTEXT('POINT(1 0)',4326)),
  ( 1,ST_GEOMFROMTEXT('POINT(2 0)',4326)),
  ( 0,ST_GEOMFROMTEXT('POINT(3 0)',4326));

SELECT ST_EQUALS( (SELECT ST_COLLECT( location ) AS t FROM t1),
  ST_GEOMFROMTEXT('MULTIPOINT(0 0,0 0,1 0,2 0,3 0) ',4326)) AS equals;
+--------+
| equals |
+--------+
|      1 |
+--------+
```

See Also

- Geometry Constructors
- ST_AsText

This page is licensed: CC BY-SA / Gnu FDL

ST_GeoHash

> **Note:**
>
> ST_GeoHash is available from MariaDB 12.0.

Syntax

```
ST_GeoHash(longitude, latitude, max_length)
ST_GeoHash(point, max_length)
```

Description

Returns the geohash corresponding to the input values, or NULL if any argument is NULL. Geohashes encode latitude and longitude coordinates into a text string made up only of numeric and lowercase latin letter characters.

The `longitude` parameter is a numeric value in the interval [180, -180]. `latitude` is a numeric value in the interval [90, -90].

In the case of `point`, the x coordinate is treated as the longitude and the y coordinate is treated as the latitude. The same constraints apply.

The `max_length` parameter is the upper limit on the resulting string size and cannot exceed 100.

The ST_LatFromGeoHash function decodes a given geohash and returns the latitude.

Examples

```
SELECT ST_GeoHash(ST_GeomFromText('POINT(1 1)'),15), ST_GeoHash(0,30,15);
+-----------------------------------------------+---------------------+
| ST_GeoHash(ST_GeomFromText('POINT(1 1)'),15) | ST_GeoHash(0,30,15) |
+-----------------------------------------------+---------------------+
| s00twy01mtw037m                               | sj248j248j248j2     |
+-----------------------------------------------+---------------------+
```

See Also

- ST_LatFromGeoHash
- Geometry Constructors
- ST_GeomFromText

This page is licensed: CC BY-SA / Gnu FDL

ST_IsValid

Note:

ST_IsValid is available from MariaDB 12.0.

Syntax

```
ST_IsValid(g)
```

Description

Given a geometry input, returns 1 if the argument is geometrically valid according to the OGC specifications, 0 if the argument is not geometrically valid.

Unlike ST_Validate, requires valid GIS data, or `ERROR 3037 (22023): Invalid GIS data provided to function st_isvalid` is returned.

Examples

```
SELECT ST_IsValid(ST_GeomFromText('LINESTRING (0 0, 1 1)'));
+-----------------------------------------------------+
| ST_IsValid(ST_GeomFromText('LINESTRING (0 0, 1 1)')) |
+-----------------------------------------------------+
|                                                   1 |
+-----------------------------------------------------+

SELECT ST_IsValid(ST_GeomFromText('LINESTRING (0 0, 0 0)'));
+-----------------------------------------------------+
| ST_IsValid(ST_GeomFromText('LINESTRING (0 0, 0 0)')) |
+-----------------------------------------------------+
|                                                   0 |
+-----------------------------------------------------+
```

A POINT requires both x and y coordinates:

```
SELECT ST_IsValid(ST_GeomFromText('POINT (0)'));
ERROR 3037 (22023): Invalid GIS data provided to function st_isvalid.
```

ST_LatFromGeoHash

> **Note:**
>
> ST_LatFromGeoHash is available from MariaDB 12.0.

Syntax

```
ST_LatFromGeoHash(geohash)
```

Description

Decodes a given `geohash` string and returns the latitude in the interval [90, -90].

If the argument is NULL, the return value is NULL. If the argument is invalid, an ER_INCORRECT_TYPE error is thrown.

The ST_GeoHash function can be used to generate geohashes.

Examples

```
SELECT ST_LatFromGeoHash('zzzzzzzzz'), ST_LatFromGeoHash('xvrfxvrfxvrfxvr');
+-------------------------------+-------------------------------------+
| ST_LatFromGeoHash('zzzzzzzzz') | ST_LatFromGeoHash('xvrfxvrfxvrfxvr') |
+-------------------------------+-------------------------------------+
|                            90 |                                  30 |
+-------------------------------+-------------------------------------+
```

See Also

- ST_GeoHash

This page is licensed: CC BY-SA / Gnu FDL

ST_LongFromGeoHash

> **Note:**
>
> ST_LongFromGeoHash is available from MariaDB 12.0.

Syntax

```
ST_LongFromGeoHash(geohash)
```

Description

Decodes a given `geohash` string and returns the longitude in the interval [180, -180].

If the argument is NULL, the return value is NULL. If the argument is invalid, an ER_INCORRECT_TYPE error is thrown.

The ST_GeoHash function can be used to generate geohashes.

Examples

```
SELECT ST_LongFromGeoHash('zzzzzzzzz'), ST_LongFromGeoHash('sj248j248j248j2');
+---------------------------------+--------------------------------------+
| ST_LongFromGeoHash('zzzzzzzzz') | ST_LongFromGeoHash('sj248j248j248j2') |
+---------------------------------+--------------------------------------+
|                             180 |                                    0 |
+---------------------------------+--------------------------------------+
```

ST_PointFromGeoHash

> **Note:**
>
> ST_PointFromGeoHash is available from MariaDB 12.0.

Syntax

```
ST_PointFromGeoHash(geohash, srid)
```

Description

Takes a given `geohash` string and returns a point where the x is the longitude and the y is the latitude.

The latitude is returned as a numeric value in the interval [180, -180]. The longitude is returned as a numeric value in the interval [90, -90]. If the argument is NULL, the return value is NULL. If the argument is invalid, an ER_GIS_INVALID_DATA is thrown.

Examples

```
SELECT ST_ASTEXT(ST_POINTFROMGEOHASH("s00twy01mtw037m",0));
+----------------------------------------------------+
| ST_ASTEXT(ST_POINTFROMGEOHASH("s00twy01mtw037m",0)) |
+----------------------------------------------------+
| POINT(1 1)                                         |
+----------------------------------------------------+

SELECT ST_ASTEXT(ST_POINTFROMGEOHASH(ST_GEOHASH(180,90,20),0));
+-----------------------------------------------------------+
| ST_ASTEXT(ST_POINTFROMGEOHASH(ST_GEOHASH(180,90,20),0)) |
+-----------------------------------------------------------+
| POINT(180 90)                                             |
+-----------------------------------------------------------+
```

ST_Simplify

> **Note:**
>
> ST_Simplify is available from MariaDB 12.0.

Syntax

```
ST_Simplify(g, max_distance)
```

Description

Takes as input a geometry (g) and a double (max_distance). It applies the Ramer–Douglas–Peucker algorithm on `g` and returns the resulting geometry.

The goal of the Douglas-Peucker algorithm is to provide generalized simplifications by returning a geometry that is similar to `g` but uses only a subset of points. To perform the simplification, all the vertices that are shorter than `max_distance` are removed.

The algorithm may produce self-intersections and therefore result in invalid geometries. ST_IsValid can be used to test validity of the result.

If the max_distance is not positive or is `NULL`, an `ER_WRONG_ARGUMENT` will occur.

Examples

```
SELECT ST_AsText(ST_Simplify(ST_GeomFromText('LINESTRING(0 0,0 2,2 2,2 4,4 4,4 6,6 6)'), 0.5));
+-----------------------------------------------------------------------------------------+
| ST_AsText(ST_Simplify(ST_GeomFromText('LINESTRING(0 0,0 2,2 2,2 4,4 4,4 6,6 6)'), 0.5)) |
+-----------------------------------------------------------------------------------------+
| LINESTRING(0 0,0 2,2 2,2 4,4 4,4 6,6 6)                                                 |
+-----------------------------------------------------------------------------------------+

SELECT ST_AsText(ST_Simplify(ST_GeomFromText('LINESTRING(0 0,0 2,2 2,2 4,4 4,4 6,6 6)'), 1));
+-----------------------------------------------------------------------------------------+
| ST_AsText(ST_Simplify(ST_GeomFromText('LINESTRING(0 0,0 2,2 2,2 4,4 4,4 6,6 6)'), 1)) |
+-----------------------------------------------------------------------------------------+
| LINESTRING(0 0,0 2,2 2,2 4,6 6)                                                         |
+-----------------------------------------------------------------------------------------+
```

ST_Validate

> **Note:**
>
> ST_Validate is available from MariaDB 12.0.

Syntax

```
ST_Validate(g)
```

Description

The function checks that a given geometry is compliant with the Well-Known Binary (WKB) format and Spatial Reference System Identifier (SRID) syntax, and is geometrically valid.

It returns the geometry if it's valid, or NULL if not.

The function is useful to filter out invalid geometry data.

Examples

A POINT requires both x and y coordinates:

```
SELECT ST_ASTEXT(ST_VALIDATE(ST_GeomFromText('POINT(1 0)')));
+-----------------------------------------------------+
| ST_ASTEXT(ST_VALIDATE(ST_GeomFromText('POINT(1 0)'))) |
+-----------------------------------------------------+
| POINT(1 0)                                          |
+-----------------------------------------------------+

SELECT ST_ASTEXT(ST_VALIDATE(ST_GeomFromText('POINT(1)')));
+-----------------------------------------------------+
| ST_ASTEXT(ST_VALIDATE(ST_GeomFromText('POINT(1)'))) |
+-----------------------------------------------------+
| NULL                                                |
+-----------------------------------------------------+
```

Point Properties

See X.

Synonym for ST_X. Returns the X-coordinate value of a Point geometry as a double-precision number.

See Y.

Synonym for ST_Y. Returns the Y-coordinate value of a Point geometry as a double-precision number.

See ST_X.

Returns the X-coordinate of a Point geometry. This function extracts the horizontal coordinate value as a double-precision number.

See ST_Y.

Returns the Y-coordinate of a Point geometry. This function extracts the vertical coordinate value as a double-precision number.

This page is licensed: CC BY-SA / Gnu FDL

X

A synonym for ST_X.

This page is licensed: CC BY-SA / Gnu FDL

Y

A synonym for ST_Y.

This page is licensed: CC BY-SA / Gnu FDL

ST_X

Syntax

```
ST_X(p)
X(p)
```

Description

Returns the X-coordinate value for the point `p` as a double-precision number.

`ST_X()` and `X()` are synonyms.

Examples

```
SET @pt = 'Point(56.7 53.34)';

SELECT X(GeomFromText(@pt));
+----------------------+
| X(GeomFromText(@pt)) |
+----------------------+
|                 56.7 |
+----------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ST_Y

Syntax

```
ST_Y(p)
Y(p)
```

Description

Returns the Y-coordinate value for the point p as a double-precision number.

`ST_Y()` and `Y()` are synonyms.

Examples

```
SET @pt = 'Point(56.7 53.34)';

SELECT Y(GeomFromText(@pt));
+----------------------+
| Y(GeomFromText(@pt)) |
+----------------------+
|                53.34 |
+----------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

Polygon Properties

See CENTROID.

Synonym for ST_CENTROID. Returns the mathematical centroid of the Polygon or MultiPolygon as a Point geometry.

See AREA.

Synonym for ST_AREA. Returns the double-precision area of the Polygon or MultiPolygon, calculated in its spatial reference system.

See ExteriorRing.

Synonym for ST_ExteriorRing. Returns the exterior ring of a Polygon as a LineString.

See InteriorRingN.

Synonym for ST_InteriorRingN. Returns the N-th interior ring of a Polygon as a LineString.

See NumInteriorRings.

Synonym for ST_NumInteriorRings. Returns the number of interior rings in a Polygon geometry.

See ST_AREA.

Returns the area of a Polygon or MultiPolygon. The result is a double-precision number measured in the geometry's spatial reference units.

See ST_CENTROID.

Returns the centroid of a Polygon or MultiPolygon. The result is a Point geometry representing the mathematical center of mass.

See ST_ExteriorRing.

Returns the exterior ring of a Polygon. This function extracts the outer boundary of the polygon as a LineString geometry.

See ST_InteriorRingN.

Returns the N-th interior ring of a Polygon. This function retrieves a specific inner hole of the polygon as a LineString.

See ST_NumInteriorRings.

Returns the count of interior rings in a Polygon. This function calculates the total number of inner holes within the polygon.

NumInteriorRings

A synonym for ST_NumInteriorRings.

This page is licensed: CC BY-SA / Gnu FDL

ST_AREA

Syntax

```
ST_Area(poly)
Area(poly)
```

Description

Returns as a double-precision number the area of the Polygon value `poly`, as measured in its spatial reference system.

`ST_Area()` and `Area()` are synonyms.

Examples

```
SET @poly = 'Polygon((0 0,0 3,3 0,0 0),(1 1,1 2,2 1,1 1))';

SELECT Area(GeomFromText(@poly));
+---------------------------+
| Area(GeomFromText(@poly)) |
+---------------------------+
|                         4 |
+---------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ST_CENTROID

Syntax

```
ST_Centroid(mpoly)
Centroid(mpoly)
```

Description

Returns a point reflecting the mathematical centroid (geometric center) for the MultiPolygon *mpoly*. The resulting point will not necessarily be on the MultiPolygon.

`ST_Centroid()` and `Centroid()` are synonyms.

Examples

```
SET @poly = ST_GeomFromText('POLYGON((0 0,20 0,20 20,0 20,0 0))');
SELECT ST_AsText(ST_Centroid(@poly)) AS center;
+--------------+
| center       |
+--------------+
| POINT(10 10) |
+--------------+
```

This page is licensed: CC BY-SA / Gnu FDL

ST_ExteriorRing

Syntax

```
ST_ExteriorRing(poly)
ExteriorRing(poly)
```

Description

Returns the exterior ring of the Polygon value `poly` as a LineString.

`ST_ExteriorRing()` and `ExteriorRing()` are synonyms.

Examples

```
SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';

SELECT AsText(ExteriorRing(GeomFromText(@poly)));
+------------------------------------------+
| AsText(ExteriorRing(GeomFromText(@poly))) |
+------------------------------------------+
| LINESTRING(0 0,0 3,3 3,3 0,0 0)          |
+------------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ST_InteriorRingN

Syntax

```
ST_InteriorRingN(poly,N)
InteriorRingN(poly,N)
```

Description

Returns the N-th interior ring for the Polygon value `poly` as a LineString. Rings are numbered beginning with 1.

`ST_InteriorRingN()` and `InteriorRingN()` are synonyms.

Examples

```
SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';

SELECT AsText(InteriorRingN(GeomFromText(@poly),1));
+---------------------------------------------+
| AsText(InteriorRingN(GeomFromText(@poly),1)) |
+---------------------------------------------+
| LINESTRING(1 1,1 2,2 2,2 1,1 1)             |
+---------------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ST_NumInteriorRings

Syntax

```
ST_NumInteriorRings(poly)
NumInteriorRings(poly)
```

Description

Returns an integer containing the number of interior rings in the Polygon value `poly`.

Note that according the OpenGIS standard, a POLYGON should have exactly one ExteriorRing and all other rings should lie within that ExteriorRing and thus be the InteriorRings. Practically, however, some systems, including MariaDB's, permit polygons to have several 'ExteriorRings'. In the case of there being multiple, non-overlapping exterior rings ST_NumInteriorRings() will return `1`.

`ST_NumInteriorRings()` and `NumInteriorRings()` are synonyms.

Examples

```
SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';

SELECT NumInteriorRings(GeomFromText(@poly));
+--------------------------------------+
| NumInteriorRings(GeomFromText(@poly)) |
+--------------------------------------+
|                                    1 |
+--------------------------------------+
```

Non-overlapping 'polygon':

```
SELECT ST_NumInteriorRings(ST_PolyFromText('POLYGON((0 0,10 0,10 10,0 10,0 0),
  (-1 -1,-5 -1,-5 -5,-1 -5,-1 -1))')) AS NumInteriorRings;
+------------------+
| NumInteriorRings |
+------------------+
|                1 |
+------------------+
```

MLineFromWKB

Syntax

```
MLineFromWKB(wkb[,srid])
MultiLineStringFromWKB(wkb[,srid])
```

Description

Constructs a MULTILINESTRING value using its WKB representation and SRID.

`MLineFromWKB()` and `MultiLineStringFromWKB()` are synonyms.

Examples

```
SET @g = ST_AsBinary(MLineFromText('MULTILINESTRING((10 48,10 21,10 0),(16 0,16 23,16 48))'));

SELECT ST_AsText(MLineFromWKB(@g));
+-------------------------------------------------------+
| ST_AsText(MLineFromWKB(@g))                           |
+-------------------------------------------------------+
| MULTILINESTRING((10 48,10 21,10 0),(16 0,16 23,16 48)) |
+-------------------------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

MPointFromWKB

Syntax

```
MPointFromWKB(wkb[,srid])
MultiPointFromWKB(wkb[,srid])
```

Description

Constructs a MULTIPOINT value using its WKB representation and SRID.

`MPointFromWKB()` and `MultiPointFromWKB()` are synonyms.

Examples

```
SET @g = ST_AsBinary(MPointFromText('MultiPoint( 1 1, 2 2, 5 3, 7 2, 9 3, 8 4, 6 6, 6 9, 4 9, 1 5 )'));

SELECT ST_AsText(MPointFromWKB(@g));
+-----------------------------------------------------+
| ST_AsText(MPointFromWKB(@g))                        |
+-----------------------------------------------------+
| MULTIPOINT(1 1,2 2,5 3,7 2,9 3,8 4,6 6,6 9,4 9,1 5) |
+-----------------------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

MPolyFromWKB

Syntax

```
MPolyFromWKB(wkb[,srid])
MultiPolygonFromWKB(wkb[,srid])
```

Description

Constructs a MULTIPOLYGON value using its WKB representation and SRID.

`MPolyFromWKB()` and `MultiPolygonFromWKB()` are synonyms.

Examples

```
SET @g = ST_AsBinary(MPointFromText('MULTIPOLYGON(((28 26,28 0,84 0,84 42,28 26),(52 18,66 23,73 9,48
6,52 18)),((59 18,67 18,67 13,59 13,59 18)))'));

SELECT ST_AsText(MPolyFromWKB(@g))\G
*************************** 1. row ***************************
ST_AsText(MPolyFromWKB(@g)): MULTIPOLYGON(((28 26,28 0,84 0,84 42,28 26),(52 18,66 23,73 9,48 6,52 18)),
((59 18,67 18,67 13,59 13,59 18)))
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

MultiLineStringFromWKB

A synonym for MLineFromWKB().

This page is licensed: CC BY-SA / Gnu FDL

MultiPointFromWKB

A synonym for MPointFromWKB.

This page is licensed: CC BY-SA / Gnu FDL

MultiPolygonFromWKB

Synonym for MPolyFromWKB.

This page is licensed: CC BY-SA / Gnu FDL

PointFromWKB

A synonym for ST_PointFromWKB.

This page is licensed: CC BY-SA / Gnu FDL

PolyFromWKB

A synonym for ST_PolyFromWKB.

This page is licensed: CC BY-SA / Gnu FDL

PolygonFromWKB

A synonym for ST_PolyFromWKB.

This page is licensed: CC BY-SA / Gnu FDL

ST_AsBinary

Syntax

```
ST_AsBinary(g)
AsBinary(g)
ST_AsWKB(g)
AsWKB(g)
```

Description

Converts a value in internal geometry format to its WKB representation and returns the binary result.

`ST_AsBinary()`, `AsBinary()`, `ST_AsWKB()` and `AsWKB()` are synonyms,

Examples

```
SET @poly = ST_GeomFromText('POLYGON((0 0,0 1,1 1,1 0,0 0))');
SELECT ST_AsBinary(@poly);

SELECT ST_AsText(ST_GeomFromWKB(ST_AsWKB(@poly)));
+-------------------------------------------+
| ST_AsText(ST_GeomFromWKB(ST_AsWKB(@poly))) |
+-------------------------------------------+
| POLYGON((0 0,0 1,1 1,1 0,0 0))             |
+-------------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ST_AsWKB

A synonym for ST_AsBinary().

This page is licensed: CC BY-SA / Gnu FDL

ST_GeomCollFromWKB

Syntax

```
ST_GeomCollFromWKB(wkb[,srid])
ST_GeometryCollectionFromWKB(wkb[,srid])
GeomCollFromWKB(wkb[,srid])
GeometryCollectionFromWKB(wkb[,srid])
```

Description

Constructs a GEOMETRYCOLLECTION value using its WKB representation and SRID.

`ST_GeomCollFromWKB()`, `ST_GeometryCollectionFromWKB()`, `GeomCollFromWKB()` and `GeometryCollectionFromWKB()` are synonyms.

Examples

```
SET @g = ST_AsBinary(ST_GeomFromText('GEOMETRYCOLLECTION(
   POLYGON((5 5,10 5,10 10,5 5)),POINT(10 10))'));

SELECT ST_AsText(ST_GeomCollFromWKB(@g));
+-------------------------------------------------------------+
| ST_AsText(ST_GeomCollFromWKB(@g))                           |
+-------------------------------------------------------------+
| GEOMETRYCOLLECTION(POLYGON((5 5,10 5,10 10,5 5)),POINT(10 10)) |
+-------------------------------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ST_GeometryCollectionFromWKB

A synonym for ST_GeomCollFromWKB.

This page is licensed: CC BY-SA / Gnu FDL

ST_GeometryFromWKB

A synonym for ST_GeomFromWKB.

This page is licensed: CC BY-SA / Gnu FDL

ST_GeomFromWKB

Syntax

```
ST_GeomFromWKB(wkb[,srid])
ST_GeometryFromWKB(wkb[,srid])
GeomFromWKB(wkb[,srid])
GeometryFromWKB(wkb[,srid])
```

Description

Constructs a geometry value of any type using its WKB representation and SRID.

`ST_GeomFromWKB()`, `ST_GeometryFromWKB()`, `GeomFromWKB()` and `GeometryFromWKB()` are synonyms.

Examples

```
SET @g = ST_AsBinary(ST_LineFromText('LINESTRING(0 4, 4 6)'));

SELECT ST_AsText(ST_GeomFromWKB(@g));
+------------------------------+
| ST_AsText(ST_GeomFromWKB(@g)) |
+------------------------------+
| LINESTRING(0 4,4 6)          |
+------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ST_LineFromWKB

Syntax

```
ST_LineFromWKB(wkb[,srid])
LineFromWKB(wkb[,srid])
ST_LineStringFromWKB(wkb[,srid])
LineStringFromWKB(wkb[,srid])
```

Description

Constructs a LINESTRING value using its WKB representation and SRID.

`ST_LineFromWKB()`, `LineFromWKB()`, `ST_LineStringFromWKB()`, and `LineStringFromWKB()` are synonyms.

Examples

```
SET @g = ST_AsBinary(ST_LineFromText('LineString(0 4,4 6)'));

SELECT ST_AsText(ST_LineFromWKB(@g)) AS l;
+--------------------+
| l                  |
+--------------------+
| LINESTRING(0 4,4 6) |
+--------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ST_LineStringFromWKB

A synonym for ST_LineFromWKB.

This page is licensed: CC BY-SA / Gnu FDL

ST_MPointFromWKB

A synonym for ST_GeomFromWKB.

This page is licensed: CC BY-SA / Gnu FDL

ST_MPolyFromWKB

A synonym for ST_GeomFromWKB.

This page is licensed: CC BY-SA / Gnu FDL

ST_MultiPointFromWKB

A synonym for ST_GeomFromWKB.

This page is licensed: CC BY-SA / Gnu FDL

ST_MultiPolygonFromWKB

A synonym for ST_GeomFromWKB.

This page is licensed: CC BY-SA / Gnu FDL

ST_PointFromWKB

Syntax

```
ST_PointFromWKB(wkb[,srid])
PointFromWKB(wkb[,srid])
```

Description

Constructs a POINT value using its WKB representation and SRID.

`ST_PointFromWKB()` and `PointFromWKB()` are synonyms.

Examples

```
SET @g = ST_AsBinary(ST_PointFromText('POINT(0 4)'));

SELECT ST_AsText(ST_PointFromWKB(@g)) AS p;
+------------+
| p          |
+------------+
| POINT(0 4) |
+------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ST_PolyFromWKB

Syntax

```
ST_PolyFromWKB(wkb[,srid])
ST_PolygonFromWKB(wkb[,srid])
PolyFromWKB(wkb[,srid])
PolygonFromWKB(wkb[,srid])
```

Description

Constructs a POLYGON value using its WKB representation and SRID.

`ST_PolyFromWKB()`, `ST_PolygonFromWKB()`, `PolyFromWKB()` and `PolygonFromWKB()` are synonyms.

Examples

```
SET @g = ST_AsBinary(ST_PolyFromText('POLYGON((1 1,1 5,4 9,6 9,9 3,7 2,1 1))'));

SELECT ST_AsText(ST_PolyFromWKB(@g)) AS p;
+---------------------------------------+
| p                                     |
+---------------------------------------+
| POLYGON((1 1,1 5,4 9,6 9,9 3,7 2,1 1)) |
+---------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ST_PolygonFromWKB

A synonym for ST_PolyFromWKB.

This page is licensed: CC BY-SA / Gnu FDL

Well-Known Binary (WKB) Format

WKB stands for Well-Known Binary, a format for representing geographical and geometrical data.

WKB uses 1-byte unsigned integers, 4-byte unsigned integers, and 8-byte double-precision numbers.

- The first byte indicates the byte order. 00 for big endian, or 01 for little endian.
- The next 4 bytes indicate the geometry type. Values from 1 to 7 indicate whether the type is Point, LineString, Polygon, MultiPoint, MultiLineString, MultiPolygon, or GeometryCollection respectively.
- The 8-byte floats represent the coordinates.

Take the following example, a sequence of 21 bytes each represented by two hex digits:

```
000000000140000000000000004010000000000000
```

- It's big endian
  - 000000000140000000000000004010000000000000
- It's a POINT
  - 000000000140000000000000004010000000000000
- The X coordinate is 2.0
  - 000000000140000000000000004010000000000000
- The Y-coordinate is 4.0
  - 000000000140000000000000004010000000000000

WKT Definition

Description

The Well-Known Text (WKT) representation of Geometry is designed to exchange geometry data in ASCII form. Examples of the basic geometry types include:

Geometry Types
POINT
LINESTRING
POLYGON
MULTIPOINT
MULTILINESTRING
MULTIPOLYGON
GEOMETRYCOLLECTION
GEOMETRY

AsText

A synonym for ST_AsText().

This page is licensed: CC BY-SA / Gnu FDL

AsWKT

A synonym for ST_AsText().

This page is licensed: CC BY-SA / Gnu FDL

GeomCollFromText

A synonym for ST_GeomCollFromText.

This page is licensed: CC BY-SA / Gnu FDL

GeometryCollectionFromText

A synonym for ST_GeomCollFromText.

This page is licensed: CC BY-SA / Gnu FDL

GeometryFromText

A synonym for ST_GeomFromText.

This page is licensed: CC BY-SA / Gnu FDL

GeomFromText

A synonym for ST_GeomFromText.

This page is licensed: CC BY-SA / Gnu FDL

LineFromText

A synonym for ST_LineFromText.

This page is licensed: CC BY-SA / Gnu FDL

LineStringFromText

A synonym for ST_LineFromText.

This page is licensed: CC BY-SA / Gnu FDL

MLineFromText

Syntax

```
MLineFromText(wkt[,srid])
MultiLineStringFromText(wkt[,srid])
```

Description

Constructs a MULTILINESTRING value using its WKT representation and SRID.

`MLineFromText()` and `MultiLineStringFromText()` are synonyms.

Examples

```
CREATE TABLE gis_multi_line (g MULTILINESTRING);
SHOW FIELDS FROM gis_multi_line;
INSERT INTO gis_multi_line VALUES
    (MultiLineStringFromText('MULTILINESTRING((10 48,10 21,10 0),(16 0,16 23,16 48))')),
    (MLineFromText('MULTILINESTRING((10 48,10 21,10 0))')),
    (MLineFromWKB(AsWKB(MultiLineString(
      LineString(Point(1, 2), Point(3, 5)),
      LineString(Point(2, 5), Point(5, 8), Point(21, 7))))));
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

MPointFromText

Syntax

```
MPointFromText(wkt[,srid])
MultiPointFromText(wkt[,srid])
```

Description

Constructs a MULTIPOINT value using its WKT representation and SRID.

`MPointFromText()` and `MultiPointFromText()` are synonyms.

Examples

```
CREATE TABLE gis_multi_point (g MULTIPOINT);
SHOW FIELDS FROM gis_multi_point;
INSERT INTO gis_multi_point VALUES
    (MultiPointFromText('MULTIPOINT(0 0,10 10,10 20,20 20)')),
    (MPointFromText('MULTIPOINT(1 1,11 11,11 21,21 21)')),
    (MPointFromWKB(AsWKB(MultiPoint(Point(3, 6), Point(4, 10)))));
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

MPolyFromText

Syntax

```
MPolyFromText(wkt[,srid])
MultiPolygonFromText(wkt[,srid])
```

Description

Constructs a MULTIPOLYGON value using its WKT representation and SRID.

`MPolyFromText()` and `MultiPolygonFromText()` are synonyms.

Examples

```
CREATE TABLE gis_multi_polygon  (g MULTIPOLYGON);
SHOW FIELDS FROM gis_multi_polygon;
INSERT INTO gis_multi_polygon VALUES
    (MultiPolygonFromText('MULTIPOLYGON(
       ((28 26,28 0,84 0,84 42,28 26),(52 18,66 23,73 9,48 6,52 18)),
       ((59 18,67 18,67 13,59 13,59 18)))')),
    (MPolyFromText('MULTIPOLYGON(
       ((28 26,28 0,84 0,84 42,28 26),(52 18,66 23,73 9,48 6,52 18)),
       ((59 18,67 18,67 13,59 13,59 18)))')),
    (MPolyFromWKB(AsWKB(MultiPolygon(Polygon(
       LineString(Point(0, 3), Point(3, 3), Point(3, 0), Point(0, 3)))))));
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

MultiLineStringFromText

A synonym for MLineFromText.

This page is licensed: CC BY-SA / Gnu FDL

MultiPointFromText

A synonym for MPointFromText.

This page is licensed: CC BY-SA / Gnu FDL

MultiPolygonFromText

A synonym for MPolyFromText.

This page is licensed: CC BY-SA / Gnu FDL

PointFromText

A synonym for ST_PointFromText.

This page is licensed: CC BY-SA / Gnu FDL

PolyFromText

A synonym for ST_PolyFromText.

This page is licensed: CC BY-SA / Gnu FDL

PolygonFromText

A synonym for ST_PolyFromText.

This page is licensed: CC BY-SA / Gnu FDL

ST_AsText

Syntax

```
ST_AsText(g)
AsText(g)
ST_AsWKT(g)
AsWKT(g)
```

Description

Converts a value in internal geometry format to its WKT representation and returns the string result.

`ST_AsText()`, `AsText()`, `ST_AsWKT()` and `AsWKT()` are all synonyms.

Examples

```
SET @g = 'LineString(1 1,4 4,6 6)';

SELECT ST_AsText(ST_GeomFromText(@g));
+--------------------------------+
| ST_AsText(ST_GeomFromText(@g)) |
+--------------------------------+
| LINESTRING(1 1,4 4,6 6)        |
+--------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ST_ASWKT

A synonym for ST_ASTEXT().

This page is licensed: CC BY-SA / Gnu FDL

ST_GeomCollFromText

Syntax

```
ST_GeomCollFromText(wkt[,srid])
ST_GeometryCollectionFromText(wkt[,srid])
GeomCollFromText(wkt[,srid])
GeometryCollectionFromText(wkt[,srid])
```

Description

Constructs a GEOMETRYCOLLECTION value using its WKT representation and SRID.

`ST_GeomCollFromText()`, `ST_GeometryCollectionFromText()`, `GeomCollFromText()` and `GeometryCollectionFromText()` are all synonyms.

Example

```
CREATE TABLE gis_geometrycollection  (g GEOMETRYCOLLECTION);
SHOW FIELDS FROM gis_geometrycollection;
INSERT INTO gis_geometrycollection VALUES
    (GeomCollFromText('GEOMETRYCOLLECTION(POINT(0 0), LINESTRING(0 0,10 10))')),
    (GeometryFromWKB(AsWKB(GeometryCollection(Point(44, 6), LineString(Point(3, 6), Point(7, 9))))),
    (GeomFromText('GeometryCollection()')),
    (GeomFromText('GeometryCollection EMPTY'));
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ST_GeometryCollectionFromText

A synonym for ST_GeomCollFromText.

This page is licensed: CC BY-SA / Gnu FDL

ST_GeometryFromText

A synonym for ST_GeomFromText.

This page is licensed: CC BY-SA / Gnu FDL

ST_GeomFromText

Syntax

```
ST_GeomFromText(wkt[,srid])
ST_GeometryFromText(wkt[,srid])
GeomFromText(wkt[,srid])
GeometryFromText(wkt[,srid])

ST_MultiLineStringFromText(wkt[,srid])
ST_MLineFromText(wkt[,srid])
ST_MPointFromText(wkt[,srid])
ST_MultiPointFromText(wkt[,srid])
```

Description

Constructs a geometry value of any type using its WKT representation and SRID.

`GeomFromText()`, `GeometryFromText()`, `ST_GeomFromText()`, `ST_GeometryFromText()`, `ST_MultiLineStringFromText`, `ST_MLineFromText`, `ST_MultiPolyFromText` and `ST_MPolygonFromText` are all synonyms.

Example

```
SET @g = ST_GEOMFROMTEXT('POLYGON((1 1,1 5,4 9,6 9,9 3,7 2,1 1))');
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ST_LineFromText

Syntax

```
ST_LineFromText(wkt[,srid])
ST_LineStringFromText(wkt[,srid])
LineFromText(wkt[,srid])
LineStringFromText(wkt[,srid])
```

Description

Constructs a LINESTRING value using its WKT representation and SRID.

`ST_LineFromText()`, `ST_LineStringFromText()`, `ST_LineFromText()` and `ST_LineStringFromText()` are all synonyms.

Examples

```
CREATE TABLE gis_line  (g LINESTRING);
SHOW FIELDS FROM gis_line;
INSERT INTO gis_line VALUES
    (LineFromText('LINESTRING(0 0,0 10,10 0)')),
    (LineStringFromText('LINESTRING(10 10,20 10,20 20,10 20,10 10)')),
    (LineStringFromWKB(AsWKB(LineString(Point(10, 10), Point(40, 10)))));
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ST_LineStringFromText

A synonym for ST_LineFromText.

This page is licensed: CC BY-SA / Gnu FDL

ST_MPointFromText

A synonym for ST_GeomFromText.

This page is licensed: CC BY-SA / Gnu FDL

ST_MPolyFromText

A synonym for ST_GeomFromText.

This page is licensed: CC BY-SA / Gnu FDL

ST_MultiLineStringFromText

A synonym for ST_GeomFromText.

This page is licensed: CC BY-SA / Gnu FDL

ST_MultiPointFromText

A synonym for ST_GeomFromText.

This page is licensed: CC BY-SA / Gnu FDL

ST_MultiPolygonFromText

A synonym for ST_GeomFromText.

This page is licensed: CC BY-SA / Gnu FDL

ST_PointFromText

Syntax

```
ST_PointFromText(wkt[,srid])
PointFromText(wkt[,srid])
```

Description

Constructs a POINT value using its WKT representation and SRID.

`ST_PointFromText()` and `PointFromText()` are synonyms.

Examples

```
CREATE TABLE gis_point  (g POINT);
SHOW FIELDS FROM gis_point;
INSERT INTO gis_point VALUES
    (PointFromText('POINT(10 10)')),
    (PointFromText('POINT(20 10)')),
    (PointFromText('POINT(20 20)')),
    (PointFromWKB(AsWKB(PointFromText('POINT(10 20)'))));
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ST_PolyFromText

Syntax

```
ST_PolyFromText(wkt[,srid])
ST_PolygonFromText(wkt[,srid])
PolyFromText(wkt[,srid])
PolygonFromText(wkt[,srid])
```

Description

Constructs a POLYGON value using its WKT representation and SRID.

`ST_PolyFromText()`, `ST_PolygonFromText()`, `PolyFromText()` and `ST_PolygonFromText()` are all synonyms.

Examples

```
CREATE TABLE gis_polygon   (g POLYGON);
INSERT INTO gis_polygon VALUES
    (PolygonFromText('POLYGON((10 10,20 10,20 20,10 20,10 10))')),
    (PolyFromText('POLYGON((0 0,50 0,50 50,0 50,0 0), (10 10,20 10,20 20,10 20,10 10))'));
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ST_PolygonFromText

A synonym for ST_PolyFromText.

This page is licensed: CC BY-SA / Gnu FDL

ST_MLineFromText

A synonym for ST_GeomFromText.

This page is licensed: CC BY-SA / Gnu FDL

Prepared Statements

See DEALLOCATE / DROP PREPARE.

Release a prepared statement to free resources. This command removes the statement definition and its name from the current session.

See EXECUTE Statement.

Run a previously prepared statement. This command executes the statement using the specified name, optionally supplying input parameters.

See EXECUTE IMMEDIATE.

Prepare and run a dynamic SQL statement in one step. This command simplifies the process by combining the PREPARE and EXECUTE operations.

See PREPARE Statement.

Parse and optimize a SQL statement for later use. This command assigns a name to the statement, enabling efficient execution with parameters.

This page is licensed: CC BY-SA / Gnu FDL

DEALLOCATE / DROP PREPARE

Syntax

```
{DEALLOCATE | DROP} PREPARE stmt_name
```

Description

To deallocate a prepared statement produced with PREPARE, use a `DEALLOCATE PREPARE` statement that refers to the prepared statement name.

A prepared statement is implicitly deallocated when a new `PREPARE` command is issued. In that case, there is no need to use `DEALLOCATE`.

Attempting to execute a prepared statement after deallocating it results in an error, as if it was not prepared at all:

```
ERROR 1243 (HY000): Unknown prepared statement handler (stmt_name) given to EXECUTE
```

If the specified statement has not been PREPAREd, an error similar to the following will be produced:

```
ERROR 1243 (HY000): Unknown prepared statement handler (stmt_name) given to DEALLOCATE PREPARE
```

Example

See example in PREPARE.

See Also

- PREPARE Statement
- EXECUTE Statement
- EXECUTE IMMEDIATE

This page is licensed: GPLv2, originally from fill_help_tables.sql

EXECUTE Statement

Syntax

```
EXECUTE stmt_name
    [USING expression[, expression] ...]
```

Description

After preparing a statement with PREPARE, you execute it with an `EXECUTE` statement that refers to the prepared statement name. If the prepared statement contains any parameter markers, you must supply a `USING` clause that lists expressions containing the values to be bound to the parameters. The `USING` clause must name exactly as many expressions as the number of parameter markers in the statement.

You can execute a given prepared statement multiple times, passing different variables to it or setting the variables to different values before each execution.

If the specified statement has not been PREPAREd, an error similar to the following is produced:

```
ERROR 1243 (HY000): Unknown prepared statement handler (stmt_name) given to EXECUTE
```

> **CURRENT**
>
> `EXECUTE` with arbitrary expression as parameters can be used, not just user variables (@var_name).
>
> **< 10.2.3**
>
> You can only use user variables (@var_name) as parameters.

Example

See example in PREPARE.

See Also

- EXECUTE IMMEDIATE

This page is licensed: GPLv2, originally from fill_help_tables.sql

EXECUTE IMMEDIATE

Syntax

```
EXECUTE IMMEDIATE statement
    [USING param[, param] ...]

param:
    expression | IGNORE | DEFAULT
```

Description

`EXECUTE IMMEDIATE` executes a dynamic SQL statement created on the fly, which can reduce performance overhead. For example:

```
EXECUTE IMMEDIATE 'SELECT 1'
```

which is shorthand for:

```
PREPARE stmt FROM "select 1";
EXECUTE stmt;
DEALLOCATE PREPARE stmt;
```

EXECUTE IMMEDIATE supports complex expressions as prepare source and parameters:

```
EXECUTE IMMEDIATE CONCAT('SELECT COUNT(*) FROM ', 't1', ' WHERE a=?') USING 5+5;
```

Limitations: subselects and stored function calls are not supported as a prepare source.

The following examples return an error:

```
CREATE OR REPLACE FUNCTION f1() RETURNS VARCHAR(64) RETURN 'SELECT * FROM t1';
EXECUTE IMMEDIATE f1();
ERROR 1970 (42000): EXECUTE IMMEDIATE does not support subqueries or stored functions

EXECUTE IMMEDIATE (SELECT 'SELECT * FROM t1');
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that
  corresponds to your MariaDB server version for the right syntax to use near
  'SELECT 'SELECT * FROM t1')' at line 1

CREATE OR REPLACE FUNCTION f1() RETURNS INT RETURN 10;
EXECUTE IMMEDIATE 'SELECT * FROM t1 WHERE a=?' USING f1();
ERROR 1970 (42000): EXECUTE..USING does not support subqueries or stored functions

EXECUTE IMMEDIATE 'SELECT * FROM t1 WHERE a=?' USING (SELECT 10);
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that
  corresponds to your MariaDB server version for the right syntax to use near
  'SELECT 10)' at line 1
```

One can use a user or an SP variable as a workaround:

```
CREATE OR REPLACE FUNCTION f1() RETURNS VARCHAR(64) RETURN 'SELECT * FROM t1';
SET @stmt=f1();
EXECUTE IMMEDIATE @stmt;

SET @stmt=(SELECT 'SELECT 1');
EXECUTE IMMEDIATE @stmt;

CREATE OR REPLACE FUNCTION f1() RETURNS INT RETURN 10;
SET @param=f1();
EXECUTE IMMEDIATE 'SELECT * FROM t1 WHERE a=?' USING @param;

SET @param=(SELECT 10);
EXECUTE IMMEDIATE 'SELECT * FROM t1 WHERE a=?' USING @param;
```

`EXECUTE IMMEDIATE` supports user variables and SP variables as OUT parameters:

```
DELIMITER $$
CREATE OR REPLACE PROCEDURE p1(OUT a INT)
BEGIN
  SET a:= 10;
END;
$$
DELIMITER ;
SET @a=2;
EXECUTE IMMEDIATE 'CALL p1(?)' USING @a;
SELECT @a;
+------+
| @a   |
+------+
|   10 |
+------+
```

Similar to `PREPARE`, `EXECUTE IMMEDIATE` is allowed in stored procedures but is not allowed in stored functions.

This example uses `EXECUTE IMMEDIATE` inside a stored procedure:

```
DELIMITER $$
CREATE OR REPLACE PROCEDURE p1()
BEGIN
  EXECUTE IMMEDIATE 'SELECT 1';
END;
$$
DELIMITER ;
CALL p1;
+---+
| 1 |
+---+
| 1 |
+---+
```

This script returns an error:

```
DELIMITER $$
CREATE FUNCTION f1() RETURNS INT
BEGIN
  EXECUTE IMMEDIATE 'DO 1';
  RETURN 1;
END;
$$
ERROR 1336 (0A000): Dynamic SQL is not allowed in stored function or trigger
```

`EXECUTE IMMEDIATE` can use `DEFAULT` and `IGNORE` indicators as bind parameters:

```
CREATE OR REPLACE TABLE t1 (a INT DEFAULT 10);
EXECUTE IMMEDIATE 'INSERT INTO t1 VALUES (?)' USING DEFAULT;
SELECT * FROM t1;
+------+
| a    |
+------+
|   10 |
+------+
```

EXECUTE IMMEDIATE increments the Com_execute_immediate status variable, as well as the Com_stmt_prepare, Com_stmt_execute and Com_stmt_close status variables.

Note, EXECUTE IMMEDIATE does not increment the Com_execute_sql status variable. *Com_execute_sql* is used only for PREPARE..EXECUTE.

This session screenshot demonstrates how EXECUTE IMMEDIATE affects status variables:

```
SELECT * FROM INFORMATION_SCHEMA.SESSION_STATUS WHERE VARIABLE_NAME RLIKE
  ('COM_(EXECUTE|STMT_PREPARE|STMT_EXECUTE|STMT_CLOSE)');

+-----------------------+----------------+
| VARIABLE_NAME         | VARIABLE_VALUE |
+-----------------------+----------------+
| COM_EXECUTE_IMMEDIATE | 0              |
| COM_EXECUTE_SQL       | 0              |
| COM_STMT_CLOSE        | 0              |
| COM_STMT_EXECUTE      | 0              |
| COM_STMT_PREPARE      | 0              |
+-----------------------+----------------+

EXECUTE IMMEDIATE 'SELECT 1';
+---+
| 1 |
+---+
| 1 |
+---+

SELECT * FROM INFORMATION_SCHEMA.SESSION_STATUS WHERE VARIABLE_NAME RLIKE
  ('COM_(EXECUTE|STMT_PREPARE|STMT_EXECUTE|STMT_CLOSE)');
+-----------------------+----------------+
| VARIABLE_NAME         | VARIABLE_VALUE |
+-----------------------+----------------+
| COM_EXECUTE_IMMEDIATE | 1              |
| COM_EXECUTE_SQL       | 0              |
| COM_STMT_CLOSE        | 1              |
| COM_STMT_EXECUTE      | 1              |
| COM_STMT_PREPARE      | 1              |
+-----------------------+----------------+
```

This page is licensed: CC BY-SA / Gnu FDL

PREPARE Statement

Syntax

```
PREPARE stmt_name FROM preparable_stmt
```

Description

The `PREPARE` statement prepares a statement and assigns it a name, `stmt_name`, by which to refer to the statement later. Statement names are not case sensitive. `preparable_stmt` is an expression with the text of the statement. It cannot contain stored function calls or subqueries. The text must represent a single SQL statement, not multiple statements. Within the statement, `?` characters can be used as parameter markers to indicate where data values are to be bound to the query later when you execute it. The `?` characters should not be enclosed within quotes, even if you intend to bind them to string values. Parameter markers can be used only where expressions should appear, not for SQL keywords, identifiers, and so forth.

The scope of a prepared statement is the session within which it is created. Other sessions cannot see it.

If a prepared statement with the given name already exists, it is deallocated implicitly before the new statement is prepared. This means that if the new statement contains an error and cannot be prepared, an error is returned and no statement with the given name exists.

Prepared statements can be `PREPARE` and EXECUTE in a stored procedure, but not in a stored function or trigger. Also, even if the statement is prepared with `PREPARE` in a procedure, it will not be deallocated when the procedure execution ends.

A prepared statement can access user-defined variables, but not local variables or procedure's parameters.

If the prepared statement contains a syntax error, PREPARE will fail. As a side effect, stored procedures can use it to check if a statement is valid. For example:

```
CREATE PROCEDURE `test_stmt`(IN sql_text TEXT)
BEGIN
        DECLARE EXIT HANDLER FOR SQLEXCEPTION
        BEGIN
                SELECT CONCAT(sql_text, ' is not valid');
        END;
        SET @SQL := sql_text;
        PREPARE stmt FROM @SQL;
        DEALLOCATE PREPARE stmt;
END;
```

The FOUND_ROWS() and ROW_COUNT() functions, if called immediately after `EXECUTE`, return the number of rows read or affected by the prepared statements; however, if they are called after `DEALLOCATE PREPARE`, they provide information about this statement. If the prepared statement produces errors or warnings, GET DIAGNOSTICS return information about them. `DEALLOCATE PREPARE` shouldn't clear the diagnostics area, unless it produces an error.

A prepared statement is executed with EXECUTE and released with DEALLOCATE PREPARE.

The max_prepared_stmt_count server system variable determines the number of allowed prepared statements that can be prepared on the server. If it is set to `0`, prepared statements are not allowed. If the limit is reached, an error similar to the following will be produced:

```
ERROR 1461 (42000): Can't create more than max_prepared_stmt_count statements
  (current value: 0)
```

Oracle Mode

In Oracle mode, `PREPARE stmt FROM 'SELECT :1, :2'` is used instead of `?`.

Permitted Statements

> **Note:**
>
> The following is valid from MariaDB **10.6.2.**

All statements can be prepared, except PREPARE, EXECUTE, and DEALLOCATE / DROP PREPARE.

Prior to this, not all statements can be prepared. Only the following SQL commands are permitted:

- ALTER TABLE
- ANALYZE TABLE
- BINLOG
- CACHE INDEX
- CALL
- CHANGE MASTER
- CHECKSUM {TABLE | TABLES}
- COMMIT
- {CREATE | DROP} DATABASE
- {CREATE | DROP} INDEX
- {CREATE | RENAME | DROP} TABLE
- {CREATE | RENAME | DROP} USER
- {CREATE | DROP} VIEW

- DELETE
- DESCRIBE
- DO
- EXPLAIN
- FLUSH {TABLE | TABLES | TABLES WITH READ LOCK | HOSTS | PRIVILEGES | LOGS | STATUS | MASTER | SLAVE | DES_KEY_FILE | USER_RESOURCES | QUERY CACHE | TABLE_STATISTICS | INDEX_STATISTICS | USER_STATISTICS | CLIENT_STATISTICS}
- GRANT
- INSERT
- INSTALL {PLUGIN | SONAME}
- HANDLER READ
- KILL
- LOAD INDEX INTO CACHE
- OPTIMIZE TABLE
- REPAIR TABLE
- REPLACE
- RESET {MASTER | SLAVE | QUERY CACHE}
- REVOKE
- ROLLBACK
- SELECT
- SET
- SET GLOBAL SQL_SLAVE_SKIP_COUNTER
- SET ROLE
- SET SQL_LOG_BIN
- SET TRANSACTION ISOLATION LEVEL
- SHOW EXPLAIN
- SHOW {DATABASES | TABLES | OPEN TABLES | TABLE STATUS | COLUMNS | INDEX | TRIGGERS |EVENTS | GRANTS | CHARACTER SET | COLLATION | ENGINES | [PLUGINS SONAME] | PRIVILEGES |PROCESSLIST | PROFILE | PROFILES | VARIABLES | STATUS | WARNINGS | ERRORS |TABLE_STATISTICS | INDEX_STATISTICS | USER_STATISTICS | CLIENT_STATISTICS | AUTHORS |CONTRIBUTORS}
- SHOW CREATE {DATABASE | TABLE | VIEW | PROCEDURE | FUNCTION | TRIGGER | EVENT}
- SHOW {FUNCTION | PROCEDURE} CODE
- SHOW BINLOG EVENTS
- SHOW SLAVE HOSTS
- SHOW {MASTER | BINARY} LOGS
- SHOW {MASTER | SLAVE | TABLES | INNODB | FUNCTION | PROCEDURE} STATUS
- SLAVE {START | STOP}
- TRUNCATE TABLE
- SHUTDOWN
- UNINSTALL {PLUGIN | SONAME}
- UPDATE

Synonyms are not listed here, but can be used. For example, `DESC` can be used instead of `DESCRIBE`.

Compound statements can be prepared too.

Note that if a statement can be run in a stored routine, it will work even if it is called by a prepared statement. For example, SIGNAL can't be directly prepared. However, it is allowed in stored routines. If the x() procedure contains `SIGNAL`, you can still prepare and execute the '`CALL` x();' prepared statement.

`PREPARE` supports most kinds of expressions as well, for example:

```
PREPARE stmt FROM CONCAT('SELECT * FROM ', table_name);
```

When `PREPARE` is used with a statement which is not supported, the following error is produced:

```
ERROR 1295 (HY000): This command is not supported in the prepared statement protocol yet
```

Example

```
CREATE TABLE t1 (a INT,b CHAR(10));
INSERT INTO t1 VALUES (1,"one"),(2, "two"),(3,"three");
PREPARE test FROM "select * from t1 where a=?";
SET @param=2;
EXECUTE test USING @param;
+------+------+
| a    | b    |
+------+------+
|    2 | two  |
+------+------+
SET @param=3;
EXECUTE test USING @param;
+------+-------+
| a    | b     |
+------+-------+
|    3 | three |
+------+-------+
DEALLOCATE PREPARE test;
```

Since identifiers are not permitted as prepared statements parameters, sometimes it is necessary to dynamically compose an SQL statement. This technique is called *dynamic SQL*). The following example shows how to use dynamic SQL:

```
CREATE PROCEDURE test.stmt_test(IN tab_name VARCHAR(64))
BEGIN
    SET @sql = CONCAT('SELECT COUNT(*) FROM ', tab_name);
    PREPARE stmt FROM @sql;
    EXECUTE stmt;
    DEALLOCATE PREPARE stmt;
END;

CALL test.stmt_test('mysql.user');
+----------+
| COUNT(*) |
+----------+
|        4 |
+----------+
```

Use of variables in prepared statements:

```
PREPARE stmt FROM 'SELECT @x;';

SET @x = 1;

EXECUTE stmt;
+------+
| @x   |
+------+
|    1 |
+------+

SET @x = 0;

EXECUTE stmt;
+------+
| @x   |
+------+
|    0 |
+------+

DEALLOCATE PREPARE stmt;
```

Programmatic & Compound Statements

See BEGIN END.

Group multiple SQL statements into a logical block. This construct defines a compound statement, creating a new scope for variables and exception handling.

See CASE Statement.

Complete reference for CASE Statement in MariaDB. Complete syntax guide with all options, clauses, and practical examples with comprehensive examples and.

See DECLARE CONDITION.

Define named error conditions. This statement associates a name with a specific SQLSTATE or MariaDB error code for easier handling in stored programs.

See DECLARE HANDLER.

Specify actions for error conditions. This statement defines handler routines (CONTINUE or EXIT) to manage exceptions or warnings within a block.

See DECLARE TYPE.

Define data types for Oracle compatibility. This statement allows declaring PL/SQL-style record types and associative arrays, and REF CURSOR types within stored procedures.

See DECLARE Variable.

Initialize local variables within a stored program. This statement defines variables with a specific data type and optional default value.

See FOR.

Loop through a range or cursor result set. This control flow statement repeatedly executes a block of code for each item in a specified range or query.

See GOTO.

Jump to a labeled point in the code. This Oracle-compatible statement transfers execution control to a specific label within the stored program.

See IF.

Execute code based on conditions. This control flow statement runs different blocks of SQL statements depending on whether a specified condition is true.

See ITERATE.

Restart the current loop. This statement jumps back to the beginning of a LOOP, REPEAT, or WHILE block, skipping any remaining statements in the current iteration.

See Labels.

Identify blocks and loops for flow control. Labels provide names for BEGIN…END blocks or loops, allowing them to be targeted by LEAVE, ITERATE, or GOTO statements.

See LEAVE.

Exit a labeled block or loop immediately. This statement terminates the execution of the current loop or compound statement and continues after the block.

See LOOP.

Create a simple loop construct. This statement repeatedly executes a block of code until explicitly terminated by a LEAVE statement.

See REPEAT LOOP.

Execute a block until a condition is met. This loop construct runs at least once and continues repeating as long as the UNTIL condition remains false.

See RESIGNAL.

Propagate error conditions. This statement allows a handler to pass an error condition back to the caller or modify the error information before passing it on.

See RETURN.

Exit a stored function and return a value. This statement terminates function execution and sends the specified result back to the caller.

See SELECT INTO.

Assign query results to variables. This statement retrieves column values from a single row and stores them in local variables or user-defined variables.

See SIGNAL.

Raise a custom error condition. This statement allows stored programs to generate specific error messages and SQLSTATEs to handle application logic exceptions.

See WHILE.

Execute a block while a condition is true. This loop construct checks a condition before each iteration and repeats the block as long as the condition holds.

See Using Compound Statements Outside of Stored Programs.

Use compound statements such as IF and BEGIN…END outside of stored programs, with the delimiter set appropriately.

See Cursors.

Learn about cursors in MariaDB Server's programmatic compound statements. This section details how to iterate over result sets row-by-row within stored procedures and functions.

See Diagnostics.

Learn about diagnostics in programmatic compound statements. This section covers error handling and information retrieval within stored procedures and functions for effective debugging.

BEGIN END

Syntax

```
[begin_label:] BEGIN [NOT ATOMIC]
    [statement_list]
END [end_label]
```

`NOT ATOMIC` is required when used outside of a stored procedure. Inside stored procedures or within an anonymous block, `BEGIN` alone starts a new anonymous block.

Description

`BEGIN ... END` syntax is used for writing compound statements. A compound statement can contain multiple statements, enclosed by the `BEGIN` and `END` keywords. statement_list represents a list of one or more statements, each terminated by a semicolon (i.e., `;`) statement delimiter. statement_list is optional, which means that the empty compound statement (`BEGIN END`) is legal.

Note that `END` will perform a commit. If you are running in autocommit mode, every statement will be committed separately. If you are not running in `autocommit` mode, you must execute a COMMIT or ROLLBACK after `END` to get the database up to date.

Use of multiple statements requires that a client is able to send statement strings containing the statement delimiter. This is handled in the mysql command-line client with the DELIMITERcommand.
Changing the `;` end-of-statement delimiter (for example, to `//`) allows `;` to be used in a program body.

A compound statement within a stored program can be labeled. `end_label` cannot be given unless `begin_label` also is present. If both are present, they must be the same.

`BEGIN ... END` constructs can be nested. Each block can define its own variables, a `CONDITION`, a `HANDLER` and a CURSOR, which don't exist in the outer blocks. The most local declarations override the outer objects which use the same name (see example below).

The declarations order is the following:

- DECLARE local variables
- DECLARE CONDITIONs
- DECLARE CURSORs
- DECLARE HANDLERs

Note that `DECLARE HANDLER` contains another `BEGIN ... END` construct.

Here is an example of a very simple, anonymous block:

```
BEGIN NOT ATOMIC
SET @a=1;
CREATE TABLE test.t1(a INT);
END|
```

Below is an example of nested blocks in a stored procedure:

```
CREATE PROCEDURE t( )
BEGIN
   DECLARE x TINYINT UNSIGNED DEFAULT 1;
   BEGIN
      DECLARE x CHAR(2) DEFAULT '02';
       DECLARE y TINYINT UNSIGNED DEFAULT 10;
       SELECT x, y;
   END;
   SELECT x;
END;
```

In this example, a TINYINT variable, `x` is declared in the outer block. But in the inner block `x` is redeclared as a CHAR and an `y` variable is declared. The inner SELECT shows the “new” value of `x`, and the value of `y`. But when x is selected in the outer block, the “old” value is returned. The final SELECT doesn’t try to read `y`, because it doesn’t exist in that context.

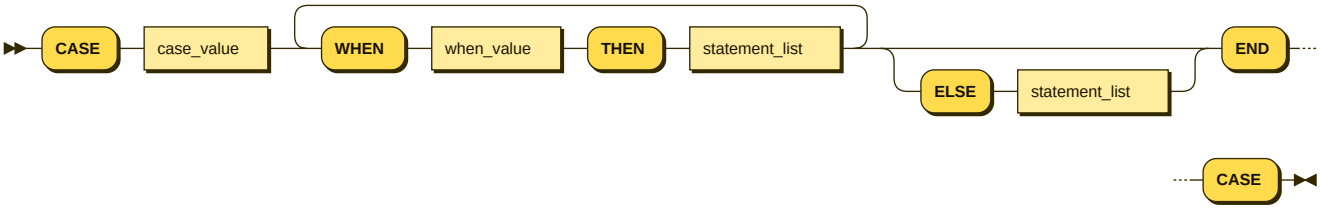
CASE Statement

Syntax

```
CASE case_value
    WHEN when_value THEN statement_list
    [WHEN when_value THEN statement_list] ...
    [ELSE statement_list]
END CASE
```



Railroad diagram of the simple CASE form — equivalent to the BNF above

Or:

```
CASE
    WHEN search_condition THEN statement_list
    [WHEN search_condition THEN statement_list] ...
    [ELSE statement_list]
END CASE
```

Description

The text on this page describes the `CASE` statement for stored programs. See the CASE OPERATOR for details on the CASE operator outside of stored programs.

The `CASE` statement for stored programs implements a complex conditional construct. If a `search_condition` evaluates to true, the corresponding SQL statement list is executed. If no search condition matches, the statement list in the `ELSE` clause is executed. Each `statement_list` consists of one or more statements.

The `CASE` statement cannot have an `ELSE NULL` clause, and it is terminated with `END CASE` instead of `END`. implements a complex conditional construct. If a `search_condition` evaluates to true, the corresponding SQL statement list is executed. If no search condition matches, the statement list in the `ELSE` clause is executed. Each `statement_list` consists of one or more statements.

If no when_value or search_condition matches the value tested and the `CASE` statement contains no `ELSE` clause, a Case not found for `CASE` statement error results.

Each statement_list consists of one or more statements; an empty `statement_list` is not allowed. To handle situations where no value is matched by any `WHEN` clause, use an `ELSE` containing an empty BEGIN … END block, as shown in this example:

```
DELIMITER |
CREATE PROCEDURE p()
BEGIN
  DECLARE v INT DEFAULT 1;
  CASE v
    WHEN 2 THEN SELECT v;
    WHEN 3 THEN SELECT 0;
    ELSE BEGIN END;
  END CASE;
END;
|
```

The indentation used here in the `ELSE` clause is for purposes of clarity only and is not otherwise significant. See Delimiters in the mariadb client for more on the use of the delimiter command.

Note: The syntax of the `CASE` statement used inside stored programs differs slightly from that of the SQL CASE expression described in CASE OPERATOR. The `CASE` statement cannot have an `ELSE NULL` clause, and it is terminated with `END CASE` instead of `END`.

DECLARE CONDITION

Syntax

```
DECLARE condition_name CONDITION FOR condition_value

condition_value:
    SQLSTATE [VALUE] sqlstate_value
  | mysql_error_code
```

Description

The `DECLARE ... CONDITION` statement defines a named error condition. It specifies a condition that needs specific handling and associates a name with that condition. Later, the name can be used in a DECLARE … HANDLER, SIGNAL or RESIGNAL statement (as long as the statement is located in the same BEGIN … END block).

Conditions must be declared after local variables, but before CURSORs and HANDLERs.

A condition_value for `DECLARE ... CONDITION` can be an SQLSTATE value (a 5-character string literal) or a MySQL error code (a number). You should not use `SQLSTATE` value '00000' or MySQL error code 0, because those indicate success rather than an error condition. If you try, or if you specify an invalid `SQLSTATE` value, an error like this is produced:

```
ERROR 1407 (42000): Bad SQLSTATE: '00000'
```

For a list of `SQLSTATE` values and MariaDB error codes, see MariaDB Error Codes.

This page is licensed: GPLv2, originally from fill_help_tables.sql

DECLARE HANDLER

Syntax

```
DECLARE handler_type HANDLER
    FOR condition_value [, condition_value] ...
    statement

handler_type:
    CONTINUE
  | EXIT
  | UNDO

condition_value:
    SQLSTATE [VALUE] sqlstate_value
  | condition_name
  | SQLWARNING
  | NOT FOUND
  | SQLEXCEPTION
  | mariadb_error_code
```

Description

The `DECLARE ... HANDLER` statement specifies handlers that each may deal with one or more conditions. If one of these conditions occurs, the specified statement is executed. statement can be a simple statement (for example, `SET var_name = value`), or it can be a compound statement written using BEGIN and END.

Handlers must be declared after local variables, a `CONDITION` and a CURSOR.

For a `CONTINUE` handler, execution of the current program continues after execution of the handler statement. For an EXIT handler, execution terminates for the BEGIN … END compound statement in which the handler is declared. (This is true even if the condition occurs in an inner block.) The `UNDO` handler type statement is not supported.

If a condition occurs for which no handler has been declared, the default action is `EXIT`.

A condition_value for `DECLARE ... HANDLER` can be any of the following values:

- An SQLSTATE value (a 5-character string literal) or a MariaDB error code (a number). You should not use `SQLSTATE` value '00000' or MariaDB error code 0, because those indicate success rather than an error condition. For a list of `SQLSTATE` values and MariaDB error codes, see MariaDB Error Codes.
- A condition name previously specified with `DECLARE ... CONDITION`. It must be in the same stored program. See DECLARE CONDITION.

- `SQLWARNING` is shorthand for the class of SQLSTATE values that begin with '01'.
- `NOT FOUND` is shorthand for the class of `SQLSTATE` values that begin with '02'. This is relevant only the context of cursors and is used to control what happens when a cursor reaches the end of a data set. If no more rows are available, a No Data condition occurs with `SQLSTATE` value 02000. To detect this condition, you can set up a handler for it (or for a `NOT FOUND` condition). An example is shown in Cursor Overview. This condition also occurs for SELECT … INTO var_list statements that retrieve no rows.
- `SQLEXCEPTION` is shorthand for the class of `SQLSTATE` values that do not begin with '00', '01', or '02'.

When an error raises, in some cases it could be handled by multiple `HANDLER`s. For example, there may be an handler for 1050 error, a separate handler for the 42S01 SQLSTATE, and another separate handler for the `SQLEXCEPTION` class: in theory all occurrences of `HANDLER` may catch the 1050 error, but MariaDB chooses the `HANDLER` with the highest precedence. Here are the precedence rules:

- Handlers which refer to an error code have the highest precedence.
- Handlers which refer to a SQLSTATE come next.
- Handlers which refer to an error class have the lowest precedence.

In some cases, a statement could produce multiple errors. If this happens, in some cases multiple handlers could have the highest precedence. In such cases, the choice of the handler is indeterminate.

Note that if an error occurs within a `CONTINUE HANDLER` block, it can be handled by another `HANDLER`. However, a `HANDLER` which is already in the stack (that is, it has been called to handle an error and its execution didn't finish yet) cannot handle new errors—this prevents endless loops. For example, suppose that a stored procedure contains a `CONTINUE HANDLER` for `SQLWARNING` and another `CONTINUE HANDLER` for `NOT FOUND`. At some point, a `NOT FOUND` error occurs, and the execution enters the `NOT FOUND HANDLER`. But within that handler, a warning occurs, and the execution enters the `SQLWARNING HANDLER`. If another `NOT FOUND` error occurs, it cannot be handled again by the `NOT FOUND HANDLER`, because its execution is not finished.

When a `DECLARE HANDLER` block can handle more than one error condition, it may be useful to know which errors occurred. To do so, you can use the GET DIAGNOSTICS statement.

An error that is handled by a `DECLARE HANDLER` construct can be issued again using the RESIGNAL statement.

Below is an example using `DECLARE HANDLER`:

```
CREATE TABLE test.t (s1 INT, PRIMARY KEY (s1));

DELIMITER //

CREATE PROCEDURE handlerdemo ( )
     BEGIN
       DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;
       SET @x = 1;
       INSERT INTO test.t VALUES (1);
       SET @x = 2;
       INSERT INTO test.t VALUES (1);
       SET @x = 3;
     END;
     //

DELIMITER ;

CALL handlerdemo( );

SELECT @x;
+------+
| @x   |
+------+
|    3 |
+------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

DECLARE TYPE

> **Note:**
>
> This feature is available from MariaDB 12.1.

Overview

The `DECLARE TYPE` declaration specifies user-defined data types that must be compatible with Oracle within stored procedures and anonymous blocks. It provides Oracle-compatible type declarations, such as record types, associative arrays, and `REF CURSOR` types, which allows for more flexible data handling and better compatibility with Oracle PL/SQL.

Associative arrays (`INDEX BY` tables) offer an in-memory key-value structure for quick data storage and effective lookups. REF CURSOR types allow for the creation of cursor variables that refer to query result sets and can be passed between program blocks.

The general syntax for defining associative array types is as follows:

```
DECLARE
   TYPE type_name TABLE OF rec_type_name INDEX BY idx_type_name
```

- `type_name` supports explicit and anchored data types (for instance, `t1.col1%TYPE`).
- `rec_type_name` supports scalar and record data types.
- The `INDEX BY` clause defines the key type using `idx_type_name` , which supports integer and string data types.

Associative Arrays

In Oracle, associative arrays (called index-by tables) are sparse collections of elements indexed by keys, which can be integers or strings.

Here's an example of how to declare an associative array in Oracle:

```
DECLARE
  TYPE array_t IS TABLE OF VARCHAR2(64) INDEX BY PLS_INTEGER;
  array array_t;
BEGIN
  array(1) := 'Hello';
  array(2) := 'World';
  DBMS_OUTPUT.PUT_LINE(array(1));
END;
```

Methods

Associative arrays support the following methods:

- `FIRST` — a function that returns the first key
- `LAST` — a function that returns the last key
- `NEXT` — a function that returns the key after the given one
- `PRIOR` — a function that returns the key before the given one
- `COUNT` — a function that returns the number of elements
- `EXISTS` — a function that returns `TRUE` if the key exists
- `DELETE` — a procedure that removes a specific key, or clears the array

While the MariaDB implementation is largely aligned with Oracle's implementation, there are a few differences:

- **Only literals as keys in the constructor**: When using constructors, keys must be literals — Oracle allows expressions.
- **Collation control**: Instead of `NLS_SORT` or `NLS_COMP`, MariaDB uses the SQL-standard `COLLATE` clause.
- **No nested associative arrays**: Arrays of arrays are not supported.

These differences are largely rooted in architectural constraints — MariaDB is aiming at staying as close to Oracle semantics as possible while maintaining performance and predictability.

Examples

Associative Array of Scalar Elements

Explicit type_name

```
DECLARE
  TYPE salary IS TABLE OF NUMBER INDEX BY VARCHAR2(20);
  salary_list salary;
  name VARCHAR2(20);
BEGIN
  salary_list('Rajnisj') := 62000;
  salary_list('James') := 78000;
  name:= salary_list.FIRST;
  WHILE name IS NOT NULL
  LOOP
    dbms_output.put_line(name || ' ' || TO_CHAR(salary_list(name)));
    name:= salary_list.NEXT(name);
  END LOOP;
END;
/
```

Anchored type_name

```
CREATE TABLE t1 (a INT);
DECLARE
  TYPE salary IS TABLE OF t1.a%TYPE INDEX BY VARCHAR2(20);
  salary_list salary;
  name VARCHAR2(20);
BEGIN
  salary_list('Rajnisj') := 62000;
  salary_list('James') := 78000;
  name:= salary_list.FIRST;
  WHILE name IS NOT NULL
  LOOP
    dbms_output.put_line(name || ' ' || TO_CHAR(salary_list(name)));
    name:= salary_list.NEXT(name);
  END LOOP;
END;
/
```

Associative Array of Records

Using Explicit Data Types

```
DECLARE
  TYPE person_t IS RECORD
  (
    first_name VARCHAR(64),
    last_name VARCHAR(64)
  );
  person person_t;
  TYPE table_of_peson_t IS TABLE OF person_t INDEX BY VARCHAR(20);
  person_by_nickname table_of_peson_t;
  nick VARCHAR(20);
BEGIN
  person_by_nickname('Monty') := person_t('Michael', 'Widenius');
  person_by_nickname('Serg') := person_t('Sergei ', 'Golubchik');
  nick:= person_by_nickname.FIRST;
  WHILE nick IS NOT NULL
  LOOP
    person:= person_by_nickname(nick);
    dbms_output.put_line(nick || ' ' || person.first_name || ' '|| person.last_name);
    nick:= person_by_nickname.NEXT(nick);
  END LOOP;
  /
```

Using Anchored Data Types

```
DROP TABLE persons;
CREATE TABLE persons (nickname VARCHAR(64), first_name VARCHAR(64), last_name VARCHAR(64));
INSERT INTO persons VALUES ('Serg','Sergei ', 'Golubchik');
INSERT INTO persons VALUES ('Monty','Michael', 'Widenius');
DECLARE
  TYPE table_of_person_t IS TABLE OF persons%ROWTYPE INDEX BY persons.nickname%TYPE;
  person_by_nickname table_of_person_t;
  nickname persons.nickname%TYPE;
  person persons%ROWTYPE;
BEGIN
  FOR rec IN (SELECT * FROM persons)
  LOOP
    person_by_nickname(rec.nickname):= rec;
  END LOOP;

  nickname:= person_by_nickname.FIRST;
  WHILE nickname IS NOT NULL
  LOOP
    person:= person_by_nickname(nickname);
    dbms_output.put_line(person.nickname || ' ' || person.first_name || ' '|| person.last_name);
    nickname:= person_by_nickname.NEXT(nickname);
  END LOOP;
END;
/
```

RECORD Types

In `sql_mode=ORACLE`, the `TYPE ... IS RECORD` statement allows you to define a user-defined data structure consisting of one or more fields.

Previously, TYPE-defined `RECORD` types could only be used in local program blocks and not in routine parameters or function `RETURN` clauses.

Syntax

```
TYPE record_type_name IS RECORD (
    field_name data_type [NOT NULL] [DEFAULT expr],
    ...
);
```

- `record_type_name` is the name of the new record type.
- Each `field_name` is a named attribute of the record.
- Each `field_type` is a valid MariaDB data type or anchored type (`%TYPE`, `%ROWTYPE`).

RECORD Types in Routine Parameters and Function RETURN

Starting with MariaDB 13.0.1, custom types defined with `DECLARE TYPE` (including `RECORD` and `REF CURSOR`) can be used as:

- Parameters of stored procedures and functions
- `RETURN` types of stored functions

Earlier, the use of a `RECORD` type in these contexts was prohibited by the MariaDB grammar and resulted in:

```
ERROR 4161 (HY000): Unknown data type
```

This change improves compatibility with Oracle PL/SQL, especially for private helper routines inside packages and for `REF CURSOR` usage.

Using RECORDs in Routine Parameters

Starting with MariaDB 13.0.1, stored procedures within the same package can use a `RECORD` type declared inside the package body as a parameter.

```
SET sql_mode=ORACLE;
DELIMITER $$
CREATE OR REPLACE PACKAGE pkg1 AS
  PROCEDURE p1();
END;
CREATE OR REPLACE PACKAGE BODY pkg1 AS
  TYPE rec0_t IS RECORD (a INT, b VARCHAR(2), c INT);
  PROCEDURE private_p1(p0 rec0_t) AS
  BEGIN
    NULL;
  END;
  PROCEDURE p1 AS
  BEGIN
    CALL private_p1(a0);
  END;
END;
$$
DELIMITER ;
```

Using RECORDs as a Function Return Type

A `RECORD` type declared inside a package body can also be used as the return type for a stored function inside the same package.

```
SET sql_mode=ORACLE;
DELIMITER $$
CREATE OR REPLACE PACKAGE pkg1 AS
  PROCEDURE p1();
END;
CREATE OR REPLACE PACKAGE BODY pkg1 AS
  TYPE rec0_t IS RECORD (a INT, b VARCHAR(2), c INT);
  FUNCTION private_f1() RETURN rec0_t AS
  BEGIN
    RETURN NULL;
  END;
  PROCEDURE p1() AS
  BEGIN
    DO private_f1();
  END;
END;
$$
DELIMITER ;
```

Requirement

This feature requires Oracle SQL mode at package creation time. The SQL mode is stored when the package is created, so `SET sql_mode=ORACLE` must be executed before running `CREATE PACKAGE` and `CREATE PACKAGE BODY`. It does not need to be set when calling the package's stored procedures or functions.

REF CURSOR Types

MariaDB supports Oracle-compatible `REF CURSOR` type declarations as a part of the `DECLARE TYPE` statement. A `REF CURSOR` is a cursor variable that can refer to a query result set and be passed across program blocks, such as stored procedures or functions.

`REF CURSOR` types must be specified with a `TYPE` declaration before any variables of that type can be declared. It can be defined as weak or strong based on whether a return type is specified.

Syntax

```
ref_cursor_type_definition:
   TYPE type_name IS REF CURSOR [ RETURN return_type ];
```

- If `RETURN` is omitted, the cursor type is weak.
- If `RETURN` is specified, the cursor type is strong and limited to a single row structure.

Weak REF CURSOR

A weak `REF CURSOR` type is defined without a `RETURN` clause. It can be used with any query result.

```
TYPE weak_cursor IS REF CURSOR; -- weak type: no RETURN clause
```

Strong REF CURSOR

A strong `REF CURSOR` type is defined by a `RETURN` clause that defines the row structure the cursor must return.

```
TYPE storong_cursor IS REF CURSOR RETURN employees%ROWTYPE;  -- strong type
```

Supported RETURN Types

MariaDB supports the following `RETURN` clause formats:

RETURN `record_type`

The return type can be a user-defined record type. Columns that correspond to the field names and types of the record must be returned by the query run against the cursor.

```
DROP TABLE t1;
CREATE TABLE t1 (a INT,b VARCHAR(10));
INSERT INTO t1 VALUES (10,'b10');
DECLARE
  TYPE rec_t IS RECORD (a INT, b VARCHAR(19));
  TYPE cur_rec_t IS REF CURSOR RETURN rec_t;
  c0 cur_rec_t;
  r0 rec_t;
BEGIN
  OPEN c0 FOR SELECT * FROM t1;
  LOOP
    FETCH c0 INTO r0;
    EXIT WHEN c0%NOTFOUND;
    DBMS_OUTPUT.PUT_LINE(r0.a || ' ' || r0.b);
  END LOOP;
END;
```

RETURN `record_type%ROWTYPE`

The declared `RECORD` type can include anchored field types, such as `t1.b%TYPE`. This enables the record and therefore the cursor to automatically modify in the event that the underlying table column type changes.

```
DROP TABLE t1;
CREATE TABLE t1 (a INT,b VARCHAR(10));
INSERT INTO t1 VALUES (10,'b10');
DECLARE
  TYPE rec_t IS RECORD (a t1.a%TYPE, b t1.b%TYPE);
  TYPE cur_rec_t IS REF CURSOR RETURN rec_t;
  r0 rec_t;
  c0 cur_rec_t;
BEGIN
  OPEN c0 FOR SELECT * FROM t1;
  LOOP
    FETCH c0 INTO r0;
    EXIT WHEN c0%NOTFOUND;
    DBMS_OUTPUT.PUT_LINE(r0.a || ' ' || r0.b);
  END LOOP;
END;
```

RETURN `record_variable%TYPE`

The cursor's return type is determined from a defined variable using the `%TYPE` attribute. At the time of declaration, the cursor inherits the type of the variable's row structure.

```
CREATE OR REPLACE PROCEDURE p1 IS
  TYPE rec0_t IS RECORD (a INT, b VARCHAR(10));
  v0 rec0_t;
  TYPE cur0_t IS REF CURSOR RETURN v0%TYPE;
  c0 cur0_t;
BEGIN
  OPEN c0 FOR SELECT 1,2 FROM DUAL;
  FETCH c0 INTO v0;
  DBMS_OUTPUT.PUT_LINE(v0.a || v0.b);
  CLOSE c0;
END;
```

RETURN `cursor%ROWTYPE`

The row structure of an existing static cursor declared in the same block serves as the anchor for the cursor's return type. The column types and names from that cursor's `SELECT` statement are inherited by the `REF CURSOR`.

```
CREATE OR REPLACE PROCEDURE p1 IS
  CURSOR cs IS SELECT 1 AS a,2 AS b FROM DUAL;
  TYPE curs_t IS REF CURSOR RETURN cs%ROWTYPE;
  c0 curs_t;
  v0 cs%ROWTYPE;
BEGIN
  OPEN c0 FOR SELECT 1,2 FROM DUAL;
  FETCH c0 INTO v0;
  DBMS_OUTPUT.PUT_LINE(v0.a || v0.b);
  CLOSE c0;
END;
```

RETURN `table_or_view%ROWTYPE`

Using `%ROWTYPE`, the return type of the cursor is directly linked to a table or view row structure. This cursor variable can only be used with queries that return all columns from the referenced table or view in the same sequence.

```
DROP TABLE t1;
CREATE TABLE t1 (a INT,b VARCHAR(10));
INSERT INTO t1 VALUES (10,'b10');
DECLARE
  TYPE cur_rec_t IS REF CURSOR RETURN t1%ROWTYPE;
  c0 cur_rec_t;
  r0 t1%ROWTYPE;
BEGIN
  OPEN c0 FOR SELECT * FROM t1;
  LOOP
    FETCH c0 INTO r0;
    EXIT WHEN c0%NOTFOUND;
    DBMS_OUTPUT.PUT_LINE(r0.a || ' ' || r0.b);
  END LOOP;
END;
```

RETURN `cursor_variable%ROWTYPE`

The cursor's return type is derived from another `REF CURSOR` variable using `%ROWTYPE`. This allows for the connection of cursor type declarations, so that a second cursor inherits its structure from a previously specified cursor variable.

```
DROP TABLE t1;
CREATE TABLE t1 (a INT,b VARCHAR(10));
INSERT INTO t1 VALUES (10,'b10');
DECLARE
  TYPE cur1_t IS REF CURSOR RETURN t1%ROWTYPE;
  c1 cur1_t;
  TYPE cur0_t IS REF CURSOR RETURN c1%ROWTYPE;
  c0 cur0_t;
  r0 c0%ROWTYPE;
BEGIN
  OPEN c0 FOR SELECT * FROM t1;
  LOOP
    FETCH c0 INTO r0;
    EXIT WHEN c0%NOTFOUND;
    DBMS_OUTPUT.PUT_LINE(r0.a || ' ' || r0.b);
  END LOOP;
END;
```

- CREATE PROCEDURE

This page is licensed: CC BY-SA / Gnu FDL

DECLARE Variable

Syntax

```
DECLARE var_name [, var_name] ... [[ROW] TYPE OF]] type [DEFAULT value]
```

Description

This statement is used to declare local variables within stored programs. To provide a default value for the variable, include a `DEFAULT` clause. The value can be specified as an expression (even subqueries are permitted); it need not be a constant. If the `DEFAULT` clause is missing, the initial value is `NULL`.

Local variables are treated like stored routine parameters with respect to data type and overflow checking. See CREATE PROCEDURE.

Local variables must be declared before `CONDITION`s, CURSORs and `HANDLER`s.

Local variable names are not case sensitive.

The scope of a local variable is within the `BEGIN ... END` block where it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

TYPE OF / ROW TYPE OF

Anchored data types allow a data type to be defined based on another object, such as a table row, rather than specifically set in the declaration. If the anchor object changes, so will the anchored data type. This can lead to routines being easier to maintain, so that if the data type in the table is changed, it will automatically be changed in the routine as well.

Variables declared with `ROW TYPE OF` will have the same features as implicit ROW variables. It is not possible to use `ROW TYPE OF` variables in a LIMIT clause.

The real data type of `TYPE OF` and `ROW TYPE OF table_name` will become known at the very beginning of the stored routine call. ALTER TABLE or DROP TABLE statements performed inside the current routine on the tables that appear in anchors won't affect the data type of the anchored variables, even if the variable is declared after an ALTER TABLE or DROP TABLE statement.

The real data type of a `ROW TYPE OF cursor_name` variable will become known when execution enters into the block where the variable is declared. Data type instantiation will happen only once. In a cursor `ROW TYPE OF` variable that is declared inside a loop, its data type will become known on the very first iteration and won't change on further loop iterations.

The tables referenced in `TYPE OF` and `ROW TYPE OF` declarations will be checked for existence at the beginning of the stored routine call. CREATE PROCEDURE or CREATE FUNCTION will not check the referenced tables for existence.

> **Note:**
>
> **Dynamic Cursors Limitation**
>
> `ROW TYPE OF` is not supported for dynamic cursors (cursors declared for a prepared statement). This is because the cursor's structure is dependent on the prepared statement, which is not known at the time the stored procedure context is created.

Examples

```
DECLARE name VARCHAR(5) DEFAULT 'monty';
  DECLARE x INT DEFAULT 10;
  DECLARE Y SMALLINT;
```

`TYPE OF` and `ROW TYPE OF` :

```
DECLARE tmp TYPE OF t1.a; -- Get the data type from the column {{a}} in the table {{t1}}

DECLARE rec1 ROW TYPE OF t1; -- Get the row data type from the table {{t1}}

DECLARE rec2 ROW TYPE OF cur1; -- Get the row data type from the cursor {{cur1}}
```

FOR

Syntax

Integer range `FOR` loop:

```
[begin_label:]
FOR var_name IN [ REVERSE ] lower_bound .. upper_bound
DO statement_list
END FOR [ end_label ]
```

Explicit cursor `FOR` loop:

```
[begin_label:]
FOR record_name IN cursor_name [ ( cursor_actual_parameter_list)]
DO statement_list
END FOR [ end_label ]
```

Explicit cursor `FOR` loop (Oracle mode):

```
[begin_label:]
FOR record_name IN cursor_name [ ( cursor_actual_parameter_list)]
LOOP
  statement_list
END LOOP [ end_label ]
```

Implicit cursor `FOR` loop:

```
[begin_label:]
FOR record_name IN ( select_statement )
DO statement_list
END FOR [ end_label ]
```

Description

`FOR` loops allow code to be executed a fixed number of times.

In an integer range `FOR` loop, MariaDB will compare the lower bound and upper bound values, and assign the lower bound value to a counter. If `REVERSE` is not specified, and the upper bound value is greater than or equal to the counter, the counter will be incremented and the statement will continue, after which the loop is entered again. If the upper bound value is greater than the counter, the loop will be exited.

> **Note:**
>
> **Dynamic Cursors Limitation**
>
> `FOR` loops cannot be used with dynamic cursors (cursors declared for prepared statement names). To handle dynamic cursors, employ explicit `OPEN`, `FETCH`, and `CLOSE` statements inside a `LOOP` or similar construct.

If REVERSE is specified, the counter is decremented, and the upper bound value needs to be less than or equal for the loop to continue.

Examples

Integer range `FOR` loop:

```
CREATE TABLE t1 (a INT);

DELIMITER //

FOR i IN 1..3
DO
  INSERT INTO t1 VALUES (i);
END FOR;
//

DELIMITER ;

SELECT * FROM t1;
+------+
| a    |
+------+
|    1 |
|    2 |
|    3 |
+------+
```

`REVERSE` integer range `FOR` loop:

```
CREATE OR REPLACE TABLE t1 (a INT);

DELIMITER //
FOR i IN REVERSE 4..12
    DO
    INSERT INTO t1 VALUES (i);
END FOR;
//
Query OK, 9 rows affected (0.422 sec)

DELIMITER ;

SELECT * FROM t1;
+------+
| a    |
+------+
|   12 |
|   11 |
|   10 |
|    9 |
|    8 |
|    7 |
|    6 |
|    5 |
|    4 |
+------+
```

Explicit cursor in Oracle mode:

```
SET sql_mode=ORACLE;

CREATE OR REPLACE TABLE t1 (a INT, b VARCHAR(32));

INSERT INTO t1 VALUES (10,'b0');
INSERT INTO t1 VALUES (11,'b1');
INSERT INTO t1 VALUES (12,'b2');

DELIMITER //

CREATE OR REPLACE PROCEDURE p1(pa INT) AS
  CURSOR cur(va INT) IS
    SELECT a, b FROM t1 WHERE a=va;
BEGIN
  FOR rec IN cur(pa)
  LOOP
    SELECT rec.a, rec.b;
  END LOOP;
END;
//

DELIMITER ;

CALL p1(10);
+-------+-------+
| rec.a | rec.b |
+-------+-------+
|    10 | b0    |
+-------+-------+

CALL p1(11);
+-------+-------+
| rec.a | rec.b |
+-------+-------+
|    11 | b1    |
+-------+-------+

CALL p1(12);
+-------+-------+
| rec.a | rec.b |
+-------+-------+
|    12 | b2    |
+-------+-------+

CALL p1(13);
Query OK, 0 rows affected (0.000 sec)
```

See Also

- LOOP

This page is licensed: CC BY-SA / Gnu FDL

GOTO

Syntax

```
GOTO label
```

Description

The `GOTO` statement causes the code to jump to the specified label, and continue operating from there. It is only accepted when in Oracle mode.

Example

```
SET sql_mode=ORACLE;

DELIMITER //

CREATE OR REPLACE PROCEDURE p1 AS

BEGIN

  SELECT 1;
  GOTO label;
  SELECT 2;
  <<label>>
  SELECT 3;

END;

//

DELIMITER

CALL p1();
+---+
| 1 |
+---+
| 1 |
+---+
1 row in set (0.000 sec)

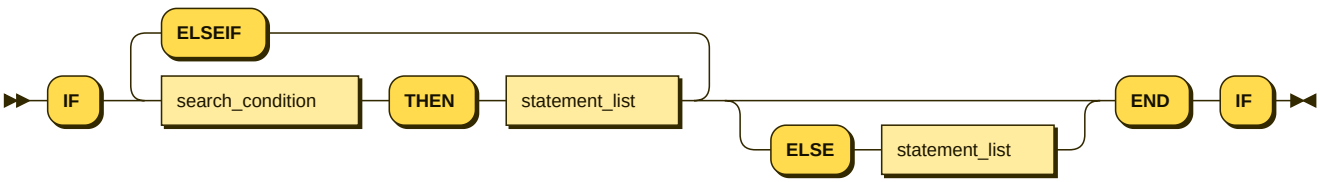
+---+
| 3 |
+---+
| 3 |
+---+
1 row in set (0.000 sec)
```

This page is licensed: CC BY-SA / Gnu FDL

IF

Syntax

```
IF search_condition THEN statement_list
    [ELSEIF search_condition THEN statement_list] ...
    [ELSE statement_list]
END IF
```



Railroad diagram of the IF statement — equivalent to the BNF above

Description

`IF` implements a basic conditional construct. If the `search_condition` evaluates to true, the corresponding SQL statement list is executed. If no `search_condition` matches, the statement list in the `ELSE` clause is executed. Each statement_list consists of one or more statements.

See Also

- The IF() function, which differs from the `IF` statement described above.
- Changes in Oracle mode.
- The CASE statement.

This page is licensed: GPLv2, originally from fill_help_tables.sql

ITERATE

Syntax

```
ITERATE label
```

`ITERATE` can appear only within LOOP, REPEAT, and WHILE statements. `ITERATE` means "do the loop again", and uses the statement's label to determine which statements to repeat. The label must be in the same stored program, not in a caller procedure.

If you try to use `ITERATE` with a non-existing label, or if the label is associated to a construct which is not a loop, the following error will be produced:

```
ERROR 1308 (42000): ITERATE with no matching label: <label_name>
```

Below is an example of how `ITERATE` might be used:

```
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
  label1: LOOP
    SET p1 = p1 + 1;
    IF p1 < 10 THEN ITERATE label1; END IF;
    LEAVE label1;
  END LOOP label1;
  SET @x = p1;
END
```

See Also

- LEAVE - Exits a loop (or any labeled code block)

This page is licensed: GPLv2, originally from fill_help_tables.sql

Labels

Syntax

```
label: <construct>
[label]
```

Labels are MariaDB identifiers which can be used to identify a BEGIN … END construct or a loop. They have a maximum length of 16 characters and can be quoted with backticks (i.e.., ```).

Labels have a start part and an end part. The start part must precede the portion of code it refers to, must be followed by a colon (`:`) and can be on the same or different line. The end part is optional and adds nothing, but can make the code more readable. If used, the end part must precede the construct's delimiter (`;`). Constructs identified by a label can be nested. Each construct can be identified by only one label.

Labels need not be unique in the stored program they belong to. However, a label for an inner loop cannot be identical to a label for an outer loop. In this case, the following error would be produced:

```
ERROR 1309 (42000): Redefining label <label_name>
```

LEAVE and ITERATE statements can be used to exit or repeat a portion of code identified by a label. They must be in the same Stored Routine, Trigger or Event which contains the target label.

Below is an example using a simple label that is used to exit a LOOP:

```
CREATE PROCEDURE `test_sp`()
BEGIN
   `my_label`:
   LOOP
      SELECT 'looping';
      LEAVE `my_label`;
   END LOOP;
   SELECT 'out of loop';
END;
```

The following label is used to exit a procedure, and has an end part:

```
CREATE PROCEDURE `test_sp`()
`my_label`:
BEGIN
   IF @var = 1 THEN
      LEAVE `my_label`;
   END IF;
   DO something();
END `my_label`;
```

This page is licensed: CC BY-SA / Gnu FDL

LEAVE

Syntax

```
LEAVE label
```

This statement is used to exit the flow control construct that has the given label. The label must be in the same stored program, not in a caller procedure. `LEAVE` can be used within BEGIN … END or loop constructs (LOOP, REPEAT, WHILE). In Stored Procedures, Triggers and Events, LEAVE can refer to the outmost `BEGIN ... END` construct; in that case, the program exits the procedure. In Stored Functions, RETURN can be used instead.

> **Note:**
>
> `LEAVE` cannot be used to exit a DECLARE HANDLER block.

If you try to `LEAVE` a non-existing label, or if you try to `LEAVE` a `HANDLER` block, the following error will be produced:

```
ERROR 1308 (42000): LEAVE with no matching label: <label_name>
```

The following example uses `LEAVE` to exit the procedure if a condition is true:

```
CREATE PROCEDURE proc(IN p TINYINT)
CONTAINS SQL
`whole_proc`:
BEGIN
   SELECT 1;
   IF p < 1 THEN
      LEAVE `whole_proc`;
   END IF;
   SELECT 2;
END;

CALL proc(0);
+---+
| 1 |
+---+
| 1 |
+---+
```

See Also

- ITERATE - Repeats a loop execution

This page is licensed: GPLv2, originally from fill_help_tables.sql

LOOP

Syntax

```
[begin_label:] LOOP
    statement_list
END LOOP [end_label]
```

Description

`LOOP` implements a simple loop construct, enabling repeated execution of the statement list, which consists of one or more statements, each terminated by a semicolon (i.e., `;`) statement delimiter. The statements within the loop are repeated until the loop is exited; usually this is accomplished with a LEAVE statement.

A `LOOP` statement can be labeled. `end_label` cannot be given unless `begin_label` also is present. If both are present, they must be the same.

See Delimiters in the mariadb client for more on delimiter usage in the client.

See Also

- LOOP in Oracle mode
- ITERATE
- LEAVE
- FOR Loops

This page is licensed: GPLv2, originally from fill_help_tables.sql

REPEAT LOOP

Syntax

```
[begin_label:] REPEAT
    statement_list
UNTIL search_condition
END REPEAT [end_label]
```

The statement list within a `REPEAT` statement is repeated until the search_condition is true. Thus, a `REPEAT` always enters the loop at least once. statement_list consists of one or more statements, each terminated by a semicolon (i.e., `;`) statement delimiter.

A `REPEAT` statement can be labeled. end_label cannot be given unless begin_label is also present. If both are present, they must be the same.

See Delimiters in the mariadb client for more on client delimiter usage.

```
DELIMITER //

CREATE PROCEDURE dorepeat(p1 INT)
  BEGIN
    SET @x = 0;
    REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
  END
//

CALL dorepeat(1000)//

SELECT @x//
+------+
| @x   |
+------+
| 1001 |
+------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

RESIGNAL

Syntax

```
RESIGNAL [error_condition]
    [SET error_property
    [, error_property] ...]

error_condition:
    SQLSTATE [VALUE] 'sqlstate_value'
  | condition_name

error_property:
    error_property_name = <error_property_value>

error_property_name:
    CLASS_ORIGIN
  | SUBCLASS_ORIGIN
  | MESSAGE_TEXT
  | MYSQL_ERRNO
  | CONSTRAINT_CATALOG
  | CONSTRAINT_SCHEMA
  | CONSTRAINT_NAME
  | CATALOG_NAME
  | SCHEMA_NAME
  | TABLE_NAME
  | COLUMN_NAME
  | CURSOR_NAME
```

Description

The syntax of `RESIGNAL` and its semantics are very similar to SIGNAL. This statement can only be used within an error HANDLER. It produces an error, like SIGNAL. `RESIGNAL` clauses are the same as `SIGNAL`, except that they all are optional, even SQLSTATE. All the properties which are not specified in `RESIGNAL`, will be identical to the

properties of the error that was received by the error HANDLER. For a description of the clauses, see diagnostics area.

> **Note:**
>
> `RESIGNAL` does not empty the diagnostics area. It just appends another error condition.

`RESIGNAL`, without any clauses, produces an error which is identical to the error that was received by HANDLER.

If used out of a HANDLER construct, RESIGNAL produces the following error:

```
ERROR 1645 (0K000): RESIGNAL when handler not active
```

CURRENT

If a HANDLER contains a CALL to another procedure, that procedure can use `RESIGNAL`, but trying to do this raises the above error.

< 5.6

If a HANDLER contains a CALL to another procedure, that procedure can use `RESIGNAL`.

For a list of `SQLSTATE` values and MariaDB error codes, see MariaDB Error Codes.

The following procedure tries to query two tables which don't exist, producing a 1146 error in both cases. Those errors will trigger the HANDLER. The first time the error will be ignored, and the client will not receive it, but the second time, the error is re-signaled, so the client will receive it.

```
CREATE PROCEDURE test_error( )
BEGIN
   DECLARE CONTINUE HANDLER
      FOR 1146
   BEGIN
   IF @hide_errors IS FALSE THEN
      RESIGNAL;
   END IF;
   END;
   SET @hide_errors = TRUE;
   SELECT 'Next error will be ignored' AS msg;
   SELECT `c` FROM `temptab_one`;
   SELECT 'Next error won''t be ignored' AS msg;
   SET @hide_errors = FALSE;
   SELECT `c` FROM `temptab_two`;
END;

CALL test_error( );

+----------------------------+
| msg                        |
+----------------------------+
| Next error will be ignored |
+----------------------------+

+----------------------------+
| msg                         |
+----------------------------+
| Next error won't be ignored |
+----------------------------+

ERROR 1146 (42S02): Table 'test.temptab_two' doesn't exist
```

The following procedure re-signals an error, modifying only the error message to clarify the cause of the problem.

```
CREATE PROCEDURE test_error()
BEGIN
   DECLARE CONTINUE HANDLER
   FOR 1146
   BEGIN
      RESIGNAL SET
      MESSAGE_TEXT = '`temptab` does not exist';
   END;
   SELECT `c` FROM `temptab`;
END;

CALL test_error( );
ERROR 1146 (42S02): `temptab` does not exist
```

```
CREATE PROCEDURE handle_error()
BEGIN
  RESIGNAL;
END;
CREATE PROCEDURE p()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION CALL p();
  SIGNAL SQLSTATE '45000';
END;
```

See Also

- Diagnostics Area
- SIGNAL
- HANDLER

- MariaDB Error Codes

This page is licensed: CC BY-SA / Gnu FDL

RETURN

Syntax

```
RETURN expr
```

The `RETURN` statement terminates execution of a stored function and returns the value *`expr`* to the function caller. There must be at least one `RETURN` statement in a stored function. If the function has multiple exit points, all exit points must have a `RETURN`.

This statement is not used in stored procedures, triggers, or events. LEAVE can be used instead.

The following example shows that `RETURN` can return the result of a scalar subquery:

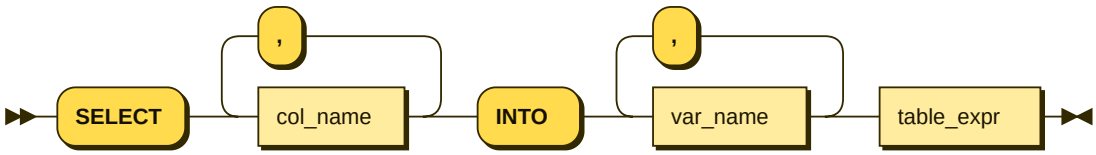
```
CREATE FUNCTION users_count() RETURNS BOOL
   READS SQL DATA
BEGIN
   RETURN (SELECT COUNT(DISTINCT User) FROM mysql.user);
END;
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

SELECT INTO

Syntax

```
SELECT col_name [, col_name] ...
    INTO var_name [, var_name] ...
    table_expr
```



Railroad diagram of SELECT INTO — equivalent to the BNF above

Description

`SELECT ... INTO` enables selected columns to be stored directly into variables. No resultset is produced. The query should return a single row. If the query returns no rows, a warning with error code 1329 occurs (`No data`), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (Result consisted of more than one row). If it is possible that the statement may retrieve multiple rows, you can use `LIMIT 1` to limit the result set to a single row.

The `INTO` clause can also be specified at the end of the statement.

In the context of such statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log.

This statement can be used with both local variables and user-defined variables.

For the complete syntax, see SELECT.

Another way to set a variable's value is the SET statement.

`SELECT ... INTO` results are not stored in the query cache even if `SQL_CACHE` is specified.

Examples

```
SELECT id, data INTO @x,@y
FROM test.t1 LIMIT 1;
SELECT * FROM t1 WHERE t1.a=@x AND t1.b=@y
```

If you want to use this construct with `UNION` you have to use the syntax:

```
SELECT  * INTO @x FROM (SELECT t1.a FROM t1 UNION SELECT t2.a FROM t2) dt;
```

See Also

- SELECT - full SELECT syntax.
- SELECT INTO OUTFILE - formatting and writing the result to an external file.
- SELECT INTO DUMPFILE - binary-safe writing of the unformatted results to an external file.

This page is licensed: GPLv2, originally from fill_help_tables.sql

SIGNAL

Syntax

```
SIGNAL error_condition
    [SET error_property
    [, error_property] ...]

error_condition:
    SQLSTATE [VALUE] 'sqlstate_value'
  | condition_name

error_property:
    error_property_name = <error_property_value>

error_property_name:
    CLASS_ORIGIN
  | SUBCLASS_ORIGIN
  | MESSAGE_TEXT
  | MYSQL_ERRNO
  | CONSTRAINT_CATALOG
  | CONSTRAINT_SCHEMA
  | CONSTRAINT_NAME
  | CATALOG_NAME
  | SCHEMA_NAME
  | TABLE_NAME
  | COLUMN_NAME
  | CURSOR_NAME
```

`SIGNAL` empties the diagnostics area and produces a custom error. This statement can be used anywhere but is generally useful when used inside a stored program. When the error is produced, it can be caught by a HANDLER. If not, the current stored program, or the current statement, will terminate with the specified error.

Sometimes an error HANDLER just needs to SIGNAL the same error it received, optionally with some changes. Usually, the RESIGNAL statement is the most convenient way to do this.

`error_condition` can be an SQLSTATE value, or a named error condition defined via DECLARE CONDITION. SQLSTATE must be a constant string consisting of five characters. These codes are standard to ODBC and ANSI SQL. For customized errors, the recommended SQLSTATE is '45000'. For a list of SQLSTATE values used by MariaDB, see the MariaDB Error Codes page. The SQLSTATE can be read via the API method `mysql_sqlstate()`.

To specify error properties user-defined variables and local variables can be used, as well as character set conversions (but you can't set a collation).

The error properties, their type and their default values are explained in the diagnostics area page.

Errors

If the `SQLSTATE` is not valid, the following error like this will be produced:

```
ERROR 1407 (42000): Bad SQLSTATE: '123456'
```

If a property is specified more than once, an error like this will be produced:

```
ERROR 1641 (42000): Duplicate condition information item 'MESSAGE_TEXT'
```

If you specify a condition name which is not declared, an error like this will be produced:

```
ERROR 1319 (42000): Undefined CONDITION: cond_name
```

If `MYSQL_ERRNO` is out of range, you will get an error like this:

```
ERROR 1231 (42000): Variable 'MYSQL_ERRNO' can't be set to the value of '0'
```

Examples

Here's what happens if SIGNAL is used in the client to generate errors:

```
SIGNAL SQLSTATE '01000';
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;

+---------+------+-----------------------------------------+
| Level   | Code | Message                                 |
+---------+------+-----------------------------------------+
| Warning | 1642 | Unhandled user-defined warning condition |
+---------+------+-----------------------------------------+
1 row in set (0.06 sec)

SIGNAL SQLSTATE '02000';
ERROR 1643 (02000): Unhandled user-defined not found condition
```

How to specify `MYSQL_ERRNO` and `MESSAGE_TEXT` properties:

```
SIGNAL SQLSTATE '45000' SET MYSQL_ERRNO=30001, MESSAGE_TEXT='H
ello, world!';

ERROR 30001 (45000): Hello, world!
```

The following code shows how to use user variables, local variables and character set conversion with `SIGNAL`:

```
CREATE PROCEDURE test_error(x INT)
BEGIN
   DECLARE errno SMALLINT UNSIGNED DEFAULT 31001;
   SET @errmsg = 'Hello, world!';
   IF x = 1 THEN
      SIGNAL SQLSTATE '45000' SET
      MYSQL_ERRNO = errno,
      MESSAGE_TEXT = @errmsg;
   ELSE
      SIGNAL SQLSTATE '45000' SET
      MYSQL_ERRNO = errno,
      MESSAGE_TEXT = _utf8'Hello, world!';
   END IF;
END;
```

How to use named error conditions:

```
CREATE PROCEDURE test_error(n INT)
BEGIN
   DECLARE `too_big` CONDITION FOR SQLSTATE '45000';
   IF n > 10 THEN
      SIGNAL `too_big`;
   END IF;
END;
```

In this example, we'll define a HANDLER for an error code. When the error occurs, we SIGNAL a more informative error which makes sense for our procedure:

```
CREATE PROCEDURE test_error()
BEGIN
   DECLARE EXIT HANDLER
   FOR 1146
   BEGIN
      SIGNAL SQLSTATE '45000' SET
      MESSAGE_TEXT = 'Temporary tables not found; did you call init() procedure?';
   END;
   -- this will produce a 1146 error
   SELECT `c` FROM `temptab`;
END;
```

- MariaDB Error Codes

This page is licensed: CC BY-SA / Gnu FDL

WHILE

Syntax

```
[begin_label:] WHILE search_condition DO
    statement_list
END WHILE [end_label]
```

Description

The statement list within a `WHILE` statement is repeated as long as the `search_condition` is true. statement_list consists of one or more statements. If the loop must be executed at least once, REPEAT … LOOP can be used instead.

A `WHILE` statement can be labeled. `end_label` cannot be given unless `begin_label` also is present. If both are present, they must be the same.

Examples

```
CREATE PROCEDURE dowhile()
BEGIN
  DECLARE v1 INT DEFAULT 5;

  WHILE v1 > 0 DO
    ...
    SET v1 = v1 - 1;
  END WHILE;
END
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

Using Compound Statements Outside of Stored Programs

Compound statements can also be used outside of stored programs.

```
delimiter |
IF @have_innodb THEN
  CREATE TABLE IF NOT EXISTS innodb_index_stats (
    database_name    VARCHAR(64) NOT NULL,
    table_name       VARCHAR(64) NOT NULL,
    index_name       VARCHAR(64) NOT NULL,
    last_update      TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    stat_name        VARCHAR(64) NOT NULL,
    stat_value       BIGINT UNSIGNED NOT NULL,
    sample_size      BIGINT UNSIGNED,
    stat_description VARCHAR(1024) NOT NULL,
    PRIMARY KEY (database_name, table_name, index_name, stat_name)
  ) ENGINE=INNODB DEFAULT CHARSET=utf8 COLLATE=utf8_bin STATS_PERSISTENT=0;
END IF|
Query OK, 0 rows affected, 2 warnings (0.00 sec)
```

Using compound statements this way is subject to following limitations:

- Only BEGIN, IF, CASE, LOOP, WHILE, REPEAT statements may start a compound statement outside of stored programs.
- BEGIN must use the `BEGIN NOT ATOMIC` syntax (otherwise it'll be confused with BEGIN that starts a transaction).
- A compound statement might not start with a label.
- A compound statement is parsed completely—note "2 warnings" in the above example, even if the condition was false (InnoDB was, indeed, disabled), and the CREATE TABLE statement was not executed, it was still parsed and the parser produced "Unknown storage engine" warning.

Inside a compound block first three limitations do not apply, one can use anything that can be used inside a stored program — including labels, condition handlers, variables, and so on:

```
BEGIN NOT ATOMIC
    DECLARE foo CONDITION FOR 1146;
    DECLARE x INT DEFAULT 0;
    DECLARE CONTINUE HANDLER FOR SET x=1;
    INSERT INTO test.t1 VALUES ("hndlr1", val, 2);
    END|
```

Example how to use `IF`:

```
IF (1>0) THEN BEGIN NOT ATOMIC SELECT 1; END ; END IF;;
```

Example of how to use `WHILE` loop:

```
DELIMITER |
BEGIN NOT ATOMIC
    DECLARE x INT DEFAULT 0;
    WHILE x <= 10 DO
        SET x = x + 1;
        SELECT x;
    END WHILE;
END|
DELIMITER ;
```

Cursors

See Cursor Overview.

Introduces cursors in MariaDB stored programs, which are non-scrollable, read-only, and asensitive, and are declared, opened, fetched from, and closed to process result rows sequentially.

See CLOSE.

CLOSE closes a previously opened cursor, raising an error if it was not open; if not closed explicitly, a cursor closes at the end of its enclosing compound statement.

See DECLARE CURSOR.

DECLARE CURSOR declares a named cursor for a SELECT or, from MariaDB 12.3, a prepared statement name, optionally with parameters, for use within a stored program.

See FETCH.

FETCH retrieves the next row from an open cursor into local variables and advances the cursor, raising a No Data condition (SQLSTATE 02000) when no more rows remain.

See OPEN.

OPEN opens a previously declared cursor and executes its associated query, optionally binding variables or expressions, so that rows can be fetched.

This page is licensed: CC BY-SA / Gnu FDL

Cursor Overview

Description

A cursor is a structure that allows you to go over records sequentially, and perform processing based on the result.

MariaDB permits cursors inside stored programs, and MariaDB cursors are non-scrollable, read-only and case-insensitive.

- Non-scrollable means that the rows can only be fetched in the order specified by the `SELECT` statement. Rows cannot be skipped, you cannot jump to a specific row, and you cannot fetch rows in reverse order.
- Read-only means that data cannot be updated through the cursor.
- Assensitive means that the cursor points to the actual underlying data. This kind of cursor is quicker than the alternative, an insensitive cursor, as no data is copied to a temporary table. However, changes to the data being used by the cursor will affect the cursor data.

Cursors are created with a DECLARE CURSOR statement and opened with an OPEN statement. Rows are read with a FETCH statement before the cursor is finally closed with a CLOSE statement.

When FETCH is issued and there are no more rows to extract, the following error is produced:

```
ERROR 1329 (02000): No data - zero rows fetched, selected, or processed
```

To avoid problems, a DECLARE HANDLER statement is generally used. The `HANDLER` should handler the 1329 error, or the '02000' SQLSTATE, or the `NOT FOUND` error class.

> **CURRENT**
>
> Cursors can be declared for a **prepared statement** name, enabling full support for **Dynamic SQL** within stored routines. The SQL Standard syntax for `<dynamic declare cursor>` is supported: a cursor is declared with the `FOR` clause to bind it to a prepared statement name, which is then prepared and opened normally. Cursors may also still SELECT from views, which can be created dynamically via prepared statements.
>
> **< 12.3**

Only **SELECT** statements are allowed for cursors, and they cannot be contained in a variable - so, they cannot be composed dynamically. However, it is possible to **SELECT** from a view. Since the **CREATE VIEW** statement can be executed as a prepared statement, it is possible to dynamically create the view that is queried by the cursor.

CURRENT

Cursors can have parameters. Cursor parameters can appear in any part of the DECLARE CURSOR `select_statement` where a stored procedure variable is allowed (select list, `WHERE`, `HAVING`, `LIMIT` etc). See DECLARE CURSOR and OPEN for syntax, and below for an example.

< 10.3

Cursors cannot have parameters.

Examples

```
CREATE TABLE c1(i INT);

CREATE TABLE c2(i INT);

CREATE TABLE c3(i INT);

DELIMITER //

CREATE PROCEDURE p1()
BEGIN
  DECLARE done INT DEFAULT FALSE;
  DECLARE x, y INT;
  DECLARE cur1 CURSOR FOR SELECT i FROM test.c1;
  DECLARE cur2 CURSOR FOR SELECT i FROM test.c2;
  DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = TRUE;

  OPEN cur1;
  OPEN cur2;

  read_loop: LOOP
    FETCH cur1 INTO x;
    FETCH cur2 INTO y;
    IF done THEN
      LEAVE read_loop;
    END IF;
    IF x < y THEN
      INSERT INTO test.c3 VALUES (x);
    ELSE
      INSERT INTO test.c3 VALUES (y);
    END IF;
  END LOOP;

  CLOSE cur1;
  CLOSE cur2;
END; //

DELIMITER ;

INSERT INTO c1 VALUES(5),(50),(500);

INSERT INTO c2 VALUES(10),(20),(30);

CALL p1;

SELECT * FROM c3;
```

```
+------+
| i    |
+------+
|    5 |
|   20 |
|   30 |
+------+
```

```
DROP PROCEDURE IF EXISTS p1;
DROP TABLE IF EXISTS t1;
CREATE TABLE t1 (a INT, b VARCHAR(10));

INSERT INTO t1 VALUES (1,'old'),(2,'old'),(3,'old'),(4,'old'),(5,'old');

DELIMITER //

CREATE PROCEDURE p1(min INT,max INT)
BEGIN
  DECLARE done INT DEFAULT FALSE;
  DECLARE va INT;
  DECLARE cur CURSOR(pmin INT, pmax INT) FOR SELECT a FROM t1 WHERE a BETWEEN pmin AND pmax;
  DECLARE CONTINUE HANDLER FOR NOT FOUND SET done=TRUE;
  OPEN cur(min,max);
  read_loop: LOOP
    FETCH cur INTO va;
    IF done THEN
      LEAVE read_loop;
    END IF;
    INSERT INTO t1 VALUES (va,'new');
  END LOOP;
  CLOSE cur;
END;
//

DELIMITER ;

CALL p1(2,4);

SELECT * FROM t1;
```

```
+------+------+
| a    | b    |
+------+------+
|    1 | old  |
|    2 | old  |
|    3 | old  |
|    4 | old  |
|    5 | old  |
|    2 | new  |
|    3 | new  |
|    4 | new  |
+------+------+
```

CLOSE

Syntax

```
CLOSE cursor_name
```

Description

This statement closes a previously opened cursor. The cursor must have been previously opened or else an error occurs.

If not closed explicitly, a cursor is closed at the end of the compound statement in which it was declared.

See Cursor Overview for an example.

See Also

- Cursor Overview
- DECLARE CURSOR
- OPEN cursor_name

This page is licensed: GPLv2, originally from fill_help_tables.sql

DECLARE CURSOR

Syntax

CURRENT

```
DECLARE cursor_name CURSOR [(cursor_formal_parameter[,...])] FOR {select_statement |
prepared_statement_name}

cursor_formal_parameter:
    [IN] name type [collate clause]
```

< 10.8

```
DECLARE cursor_name CURSOR [(cursor_formal_parameter[,...])] FOR select_statement

cursor_formal_parameter:
    name type [collate clause]
```

Description

This statement declares a cursor. Multiple cursors may be declared in a stored program, but each cursor in a given block must have a unique name.

`select_statement` is not executed until the OPEN statement is executed. It is important to remember this if the query produces an error, or calls functions which have side effects.

A `SELECT` associated to a cursor can use variables, but the query itself cannot be a variable, and cannot be dynamically composed. The `SELECT` statement cannot have an `INTO` clause.

Note:

Starting with MariaDB 12.3, the query can also be a prepared statement name, which allows the query to be dynamically composed. The `SELECT` statement cannot have an `INTO` clause.

Cursors must be declared before HANDLERs, but after local variables and CONDITIONs.

> The `DECLARE CURSOR` statement provides a cursor to a specified `SELECT` statement.
>
> To declare a cursor variable type that can be connected with multiple queries at runtime (REF CURSOR), use `DECLARE TYPE... IS REF CURSOR` in Oracle mode. See DECLARE TYPE.

Dynamic Cursors

Starting with MariaDB 12.3, a cursor can be declared for a prepared statement. This allows the use of Dynamic SQL within stored routines. The cursor is bound to a prepared statement name, which must be defined using the `PREPARE` statement before the cursor is opened.

```
CREATE OR REPLACE PROCEDURE p1(tab VARCHAR(64), min_id INTEGER)
BEGIN
  DECLARE v_id INT;
  DECLARE v_c1 VARCHAR(100);
  DECLARE no_data BOOL DEFAULT FALSE;

  -- 1. Declare cursor for the statement name 's1'
  DECLARE c1 CURSOR FOR s1;
  DECLARE CONTINUE HANDLER FOR NOT FOUND SET no_data = TRUE;

  -- 2. Prepare the statement dynamically
  PREPARE s1 FROM CONCAT('SELECT id, c1 FROM ', tab, ' WHERE id >= ?');

  -- 3. Open cursor and bind parameters
  OPEN c1 USING min_id;

  fetch_loop: LOOP
    FETCH c1 INTO v_id, v_c1;
    IF no_data THEN
      LEAVE fetch_loop;
    END IF;
    SELECT v_id, v_c1;
  END LOOP;

  CLOSE c1;
  DEALLOCATE PREPARE s1;
END;
$$

DELIMITER ;
```

Parameters

Cursors can have parameters. This is a non-standard SQL extension. Cursor parameters can appear in any part of the `DECLARE CURSOR select_statement` where a stored procedure variable is allowed (select list, `WHERE`, `HAVING`, `LIMIT`, and so forth).

IN

> **CURRENT**
>
> The `IN` qualifier is supported in the `cursor_formal_parameter` part of the syntax.
>
> **< 10.8**

> The `IN` qualifier is **not** supported in the `cursor_formal_parameter` part of the syntax.

See Cursor Overview for an example.

See Also

- Cursor Overview
- OPEN cursor_name
- FETCH cursor_name
- CLOSE cursor_name
- Cursors in Oracle mode

This page is licensed: GPLv2, originally from fill_help_tables.sql

FETCH

Syntax

```
FETCH cursor_name INTO var_name [, var_name] ...
```

Description

This statement fetches the next row (if a row exists) using the specified open cursor, and advances the cursor pointer.

`var_name` can be a local variable, but *not* a user-defined variable.

If no more rows are available, a No Data condition occurs with `SQLSTATE` value `02000`. To detect this condition, you can set up a handler for it (or for a `NOT FOUND` condition).

See Cursor Overview for an example.

See Also

- Cursor Overview

- CLOSE cursor_name
- Cursors in Oracle mode

This page is licensed: GPLv2, originally from fill_help_tables.sql

OPEN

Syntax

CURRENT

```
OPEN cursor_name [[USING variable[,...]] | [expression[,...]]];
```

ORACLE MODE

`-- From MariaDB 12.3`

```
OPEN cursor_variable FOR dynamic_sql_string;
```

< 10.3

```
OPEN cursor_name
```

Description

This statement opens a cursor which was previously declared with DECLARE CURSOR.

The query associated to the `DECLARE CURSOR` is executed when `OPEN` is executed. It is important to remember this if the query produces an error, or calls functions which have side effects.

This is necessary in order to FETCH rows from a cursor.

See Cursor Overview for an example.

Diagnostics

See Diagnostics Area.

Describes the diagnostics area that holds statement and condition information about errors, warnings, and notes produced by an SQL statement, including its properties and how it is populated and cleared.

See GET DIAGNOSTICS.

GET DIAGNOSTICS copies statement and condition information from the diagnostics area into user or local variables, reading properties such as NUMBER, RETURNED_SQLSTATE, MYSQL_ERRNO, and MESSAGE_TEXT.

See SQLSTATE.

Explains SQLSTATE, the five-character code identifying SQL error conditions by class and subclass, including the standard success, warning, and not-found classes and how they map to handler keywords.

This page is licensed: CC BY-SA / Gnu FDL

Diagnostics Area

The diagnostics area contains information about the error conditions which were produced by an SQL statement, as well as some information about the statement which generated them.

Statement Information

The statement information area contains the following data:

- `NUMBER` is the number of conditions which are present in the diagnostics area.
- `ROW_COUNT` has the same value as the ROW_COUNT() function for the statement that produced the conditions.

Condition Information

Each condition has several properties, which are explained here.

Data Types and Sizes

The following table shows the type and size of all the properties:

Property name	Property type
RETURNED_SQLSTATE	VARCHAR(5)
MYSQL_ERRNO	SMALLINT UNSIGNED
MESSAGE_TEXT	VARCHAR(512)
CLASS_ORIGIN	VARCHAR(64)
SUBCLASS_ORIGIN	VARCHAR(64)
CONSTRAINT_CATALOG	VARCHAR(64)
CONSTRAINT_SCHEMA	VARCHAR(64)
CONSTRAINT_NAME	VARCHAR(64)
CATALOG_NAME	VARCHAR(64)
SCHEMA_NAME	VARCHAR(64)
TABLE_NAME	VARCHAR(64)
COLUMN_NAME	VARCHAR(64)
CURSOR_NAME	VARCHAR(64)

These properties can never be set to `NULL`. If they are empty, the empty string is used.

Common Condition Properties

The most common ones have a value for all built-in errors, and can be read both via SQL and via the API:

`RETURNED_SQLSTATE` is the `SQLSTATE` of the condition. It is a five characters code, composed by a class (first two characters) and a subclass (last three characters). For more information about this property, refer to the SQLSTATE page.

`MYSQL_ERRNO` is the error code. Each built-in condition has a unique numeric code. 0 indicates success, but it cannot be explicitly set or read via SQL. For a list of built-in error codes, refer to MariaDB Error Codes. The API function to read it is mysql_errno().

`MESSAGE_TEXT` is a descriptive, human-readable message. For built-in errors, parsing this string is the only way to get more information about the error. For example, parsing a message like “Table ‘tab1’ already exists”, a program can find out that the missing table is tab1. The API function to read it is mysql_error().

For conditions generated by the user via `SIGNAL`, if `MYSQL_ERRNO` and `MESSAGE_TEXT` are not specified, their default values depend on the first two `SQLSTATE` characters:

- ‘00’ means ‘success’. It can not be set in any way, and can only be read via the API.
- For ‘01’ class, default `MYSQL_ERRNO` is 1642 and default `MESSAGE_TEXT` is ‘Unhandled user-defined warning condition’.
- For ‘02’ class, default `MYSQL_ERRNO` is 1643 and default `MESSAGE_TEXT` is ‘Unhandled user-defined not found condition’.
- For all other cases, including the ‘45000’ value, default `MYSQL_ERRNO` is 1644 and default `MESSAGE_TEXT` is ‘Unhandled user-defined exception condition’.

Special Condition Properties

There are more condition properties, which are never set for built-in errors. They can only be set via `SIGNAL` and `RESIGNAL` statements, and can only be read via `GET DIAGNOSTICS` - not via the API. Such properties are:

`CLASS_ORIGIN` indicates whether the `SQLSTATE` uses a standard class or a software-specific class. If it is defined in the SQL standards document ISO 9075-2 (section 24.1, SQLSTATE), this property's value is supposed to be 'ISO 9075', otherwise it is supposed to be 'MySQL'. However, any string is accepted.

`SUBCLASS_ORIGIN` indicates whether the `SQLSTATE` uses a standard subclass or a software-specific class. If the `SQLSTATE` is defined in the SQL standards document ISO 9075-2 (section 24.1, `SQLSTATE`), this property's value is supposed to be 'ISO 9075', otherwise it is supposed to be 'MySQL'. However, any string is accepted.

`SCHEMA_NAME` indicates in which schema (database) the error occurred.

`TABLE_NAME` indicates the name of the table which was accessed by the failed statement.

`COLUMN_NAME` indicates the name of the column which was accessed by the failed statement.

`CONSTRAINT_NAME` indicates the name of the constraint that was violated.

`CONSTRAINT_SCHEMA` indicates in which schema the violated constraint is located.

`CURSOR_NAME` indicates the name of the cursor which caused the error.

The following properties can be used and are defined in the standard SQL, but have no meaning because MariaDB doesn't currently support catalogs:

`CATALOG_NAME` is used by the standard SQL to indicate in which catalog the error occurred.

`CONSTRAINT_CATALOG` is used by the standard SQL to indicate in which catalog the violated constraint is located.

How the Diagnostics Area is Populated and Cleared

When a statement produces one or more error conditions (errors, warnings, notes) the conditions are inserted into the diagnostics area, and the statement information area is updated with that statement's information. Usually, this also clears all the old conditions from the diagnostics area, but there is an exception: if the new statement is a correctly parsed `RESIGNAL` or `GET DIAGNOSTICS`, the old contents will remain in the diagnostics area. `SIGNAL` clears the old conditions.

When a table-based statement (like `INSERT`) is executed, the old data in the diagnostics area is cleared even if the statement doesn't produce any condition. However, statements which don't access any table (like `SET`, or a `SELECT` with no `FROM` clause) is executed and produces no warnings, the diagnostics area remains unchanged.

The maximum number of conditions that can be in the diagnostics area is max_error_count. If this value is 0, the diagnostics area is empty. If this variable is changed, the new value takes effect with the next statement (that is, the diagnostics area is not immediately truncated).

How to Access the Diagnostics Area

The following statements explicitly add conditions to the diagnostics area:

- SIGNAL: produces a custom error.
- RESIGNAL: after an error is produced, generates a modified version of that error.

The following statements read contents from the diagnostics area:

- GET DIAGNOSTICS is the only way to read all information.
- SHOW WARNINGS shows a summary of errors, warnings and notes.
- SHOW ERRORS shows a summary of errors.

DECLARE HANDLER can be used to handle error conditions within stored programs.

DECLARE CONDITION can be used to associate an `SQLSTATE` or an error code to a name. That name can be referenced in `DECLARE HANDLER`, `SIGNAL` and `RESIGNAL` statements.

All these statements can also be executed inside a stored routine. However, only `SHOW WARNINGS` and `SHOW ERRORS` can be executed as a prepared statement. After an EXECUTE statement, the diagnostics area contains information about the prepared statement, if it produces error conditions.

This page is licensed: CC BY-SA / Gnu FDL

GET DIAGNOSTICS

```
GET [CURRENT] DIAGNOSTICS
{
    statement_property
    [, statement_property] ...
  | CONDITION condition_number
    condition_property
    [, condition_property] ...
}

statement_property:
    variable = statement_property_name

condition_property:
    variable  = condition_property_name

statement_property_name:
    NUMBER
  | ROW_COUNT

condition_property_name:
    CLASS_ORIGIN
  | SUBCLASS_ORIGIN
  | RETURNED_SQLSTATE
  | MESSAGE_TEXT
  | MYSQL_ERRNO
  | CONSTRAINT_CATALOG
  | CONSTRAINT_SCHEMA
  | CONSTRAINT_NAME
  | CATALOG_NAME
  | SCHEMA_NAME
  | TABLE_NAME
  | COLUMN_NAME
  | CURSOR_NAME
  | ROW_NUMBER
```

The diagnostics area contains information about the errors, warnings and notes which were produced by the last SQL statement. If that statement didn't produce any warnings, the diagnostics area contains information about the

last executed statement which involved a table. The `GET DIAGNOSTICS` statement copies the requested information from the diagnostics area to the specified variables. It is possible to use both user variables or local variables.

To use `GET DIAGNOSTICS`, it is important to know how the diagnostics area is structured. It has two sub-areas: the statement information area and the error conditions information area. For details, please refer to the diagnostics area page.

Each single `GET DIAGNOSTICS` command can read information from the statement information area or from a single error condition. This means that, if you have two warnings and you want to know the number of warnings, and read both the warnings, you need to issue `GET DIAGNOSTICS` three times.

The `CURRENT` keywords adds nothing to the statement, because MariaDB has only one diagnostics area.

If `GET DIAGNOSTICS` produces an error condition (because the command is properly parsed but not correctly used), the diagnostics area is not emptied, and the new condition is added.

Getting Information from a Condition

To read information from a condition, the `CONDITION` keyword must be specified and it must be followed by the condition number. This number can be specified as a constant value or as a variable. The first condition's index is 1. If the error condition does not exist, the variables will not change their value and a 1758 error will be produced ("Invalid condition number").

The condition properties that can be read with `GET DIAGNOSTICS` are the same that can be set with `SIGNAL` and `RESIGNAL` statements. They are explained in the diagnostics area page. However, there is one more property: `RETURNED_SQLSTATE`, which indicates the condition's SQLSTATE.

For a list of `SQLSTATE` values and MariaDB error codes, see MariaDB Error Codes.

The type for all the condition properties is `VARCHAR`(64), except for `MYSQL_ERRNO`, whose valid range is 1 to 65534.

ROW_NUMBER

> **CURRENT**
>
> You can use the `ROW_NUMBER` property to retrieve the row number, too, even if the error text does not mention it. This property is named `ERROR_INDEX`. `ROW_NUMBER` is a reserved word.
>
> **< 10.7**
>
> There is no way, short of parsing the error text, to know in what row an error had happened.

Examples

In the following example, a statement generates two warnings, and `GET DIAGNOSTICS` is used to get the number of warnings:

```
CREATE TABLE `test`.`t` (`c` INT) ENGINE = x;
Query OK, 0 rows affected, 2 warnings (0.19 sec)

GET DIAGNOSTICS @num_conditions = NUMBER;

SELECT @num_conditions;
+-----------------+
| @num_conditions |
+-----------------+
|               2 |
+-----------------+
```

Then we can see the warnings:

```
GET DIAGNOSTICS CONDITION 1 @sqlstate = RETURNED_SQLSTATE,
  @errno = MYSQL_ERRNO, @text = MESSAGE_TEXT;

SELECT @sqlstate, @errno, @text;
+-----------+--------+---------------------------+
| @sqlstate | @errno | @text                     |
+-----------+--------+---------------------------+
| 42000     |   1286 | Unknown storage engine 'x' |
+-----------+--------+---------------------------+

GET DIAGNOSTICS CONDITION 2 @sqlstate = RETURNED_SQLSTATE,
  @errno = MYSQL_ERRNO, @text = MESSAGE_TEXT;

SELECT @sqlstate, @errno, @text;
+-----------+--------+-----------------------------------------+
| @sqlstate | @errno | @text                                   |
+-----------+--------+-----------------------------------------+
| HY000     |   1266 | Using storage engine InnoDB for table 't' |
+-----------+--------+-----------------------------------------+
```

```
INSERT INTO t1 VALUES (4,'d',1.00104),(1,'a',1.00101),(2,'b',1.00102);
ERROR 23000: Duplicate entry '1' for key 'PRIMARY'

GET DIAGNOSTICS CONDITION 1 @row_num= ROW_NUMBER; -- from MariaDB 10.7

SELECT @row_num;
+----------+
| @row_num |
+----------+
|        2 |
+----------+
```

SQLSTATE

`SQLSTATE` is a code which identifies SQL error conditions. It composed by five characters, which can be numbers or uppercase ASCII letters. An `SQLSTATE` value consists of a class (first two characters) and a subclass (last three characters).

There are three important standard classes. They all indicate in which logical group of errors the condition falls. They match to a particular keyword which can be used with DECLARE HANDLER. Also, the `SQLSTATE` class determines the default value for the `MYSQL_ERRNO` and `MESSAGE_TEXT` condition properties.

- '00' means 'success'. It can not be set in any way and can only be read via the API.
- '01' contains all warnings and matches to the `SQLWARNING` keyword. The default `MYSQL_ERRNO` is 1642 and default `MESSAGE_TEXT` is 'Unhandled user-defined warning condition'.
- '02' is the `NOT FOUND` class. The default `MYSQL_ERRNO` is 1643 and default `MESSAGE_TEXT` is 'Unhandled user-defined not found condition'.
- All other classes match the `SQLEXCEPTION` keyword. The default `MYSQL_ERRNO` is 1644 and default `MESSAGE_TEXT` is 'Unhandled user-defined exception condition'.

The subclass, if it is set, indicates a particular condition, or a particular group of conditions within the class. However, the '000' sequence means 'no subclass'.

For example, if you try to SELECT from a table which does not exist, a 1109 error is produced, with a '42S02' `SQLSTATE`. '42' is the class and 'S02' is the subclass. This value matches to the `SQLEXCEPTION` keyword. When

`FETCH` is called for a cursor which has already reached the end, a 1329 error is produced, with a '02000' SQLSTATE. The class is '02' and there is no subclass (because '000' means 'no subclass'). It can be handled by a `NOT FOUND` handlers.

The standard SQL specification says that classes beginning with 0, 1, 2, 3, 4, A, B, C, D, E, F and G are reserved for standard-defined classes, while other classes are vendor-specific. It also says that, when the class is standard-defined, subclasses starting with those characters (except for '000') are standard-defined subclasses, while other subclasses are vendor-defined. However, MariaDB and MySQL do not strictly obey this rule.

To read the `SQLSTATE` of a particular condition which is in the diagnostics area, the GET DIAGNOSTICS statement can be used: the property is called `RETURNED_SQLSTATE`. For user-defined conditions (SIGNAL and RESIGNAL statements), a SQLSTATE value must be set via the `SQLSTATE` clause. However, SHOW WARNINGS and SHOW ERRORS do not display the `SQLSTATE`.

For user-defined conditions, MariaDB and MySQL recommend the '45000' `SQLSTATE` class.

'HY000' is called the "general error": it is the class used for built-in conditions which do not have a specific `SQLSTATE` class.

A partial list of error codes and matching `SQLSTATE` values can be found under MariaDB Error Codes.

Stored Routine Statements

See CALL.

Invoke a stored procedure. This statement executes a previously created stored procedure, optionally passing parameters and returning results.

See DO.

Execute expressions without returning a result set. This statement runs functions or expressions, often used for side effects like releasing locks.

See CREATE PROCEDURE.

Define a new stored procedure, specifying its name, parameters (`IN` , `OUT` , `INOUT`), and the SQL statements it executes.

See ALTER PROCEDURE.

Modify the characteristics of an existing stored procedure, such as its security context or comment, without changing its logic.

See DROP PROCEDURE.

Remove a stored procedure and its associated privileges from the database.

See DROP FUNCTION.

Remove a stored function from the database, deleting its definition and associated privileges.

CALL

Syntax

```
CALL sp_name([parameter[,...]])
CALL sp_name[()]
```

Description

The `CALL` statement invokes a stored procedure that was defined previously with CREATE PROCEDURE.

Stored procedure names can be specified as `database_name.procedure_name`. Procedure names and database names can be quoted with backticks (). This is necessary if they are reserved words, or contain special characters. See identifier qualifiers for details.

`CALL p()` and `CALL p` are equivalent.

If parentheses are used, any number of spaces, tab characters and newline characters are allowed between the procedure's name and the open parenthesis.

`CALL` can pass back values to its caller using parameters that are declared as `OUT` or `INOUT` parameters. If no value is assigned to an `OUT` parameter, `NULL` is assigned (and its former value is lost). To pass such values from another stored program you can use user-defined variables, local variables or routine's parameters; in other contexts, you can only use user-defined variables.

`CALL` can also be executed as a prepared statement. Placeholders can be used for `IN` parameters in all versions of MariaDB; for `OUT` and `INOUT` parameters, placeholders can be used since MariaDB 5.5.

When the procedure returns, a client program can also obtain the number of rows affected for the final statement executed within the routine: At the SQL level, call the ROW_COUNT() function; from the C API, call the `mysql_affected_rows()` function.

If the `CLIENT_MULTI_RESULTS` API flag is set, `CALL` can return any number of result sets and the called stored procedure can execute prepared statements. If it is not set, at most one result set can be returned and prepared statements cannot be used within procedures.

This page is licensed: GPLv2, originally from fill_help_tables.sql

DO

Syntax

```
DO expr [, expr] ...
```

Description

`DO` executes the expressions but does not return any results. In most respects, `DO` is shorthand for `SELECT expr, ...,` but has the advantage that it is slightly faster when you do not care about the result.

`DO` is useful primarily with functions that have side effects, such as RELEASE_LOCK().

Table Statements

See ALTER.

Access the reference for `ALTER` statements. This section lists commands to modify existing database objects, including tables, databases, users, and servers.

See ALTER TABLE.

Complete `ALTER TABLE` guide for MariaDB. Complete syntax for modifying columns, indexes, constraints, and table properties with comprehensive examples.

See ANALYZE TABLE.

Analyze and store key distribution. This statement updates index statistics used by the optimizer to choose the best execution plan.

See CHECK TABLE.

Check tables or views for errors. This statement verifies the integrity of table structure and data for supported storage engines.

See CHECK VIEW.

Verify the validity of a view's algorithm. This statement checks if the view definition is correct and references existing tables.

See CHECKSUM TABLE.

Report a checksum for table contents. This statement calculates a value to compare tables, useful for verifying replication consistency.

See CREATE TABLE.

Complete guide to creating tables in MariaDB. Complete `CREATE TABLE` syntax for data types, constraints, indexes, and storage engines for production use.

See DELETE.

Complete guide to deleting data in MariaDB. Complete `DELETE` syntax with `WHERE` filtering, `JOIN` operations, and safety considerations for production use.

See DROP TABLE.

Complete `DROP TABLE` syntax: `TEMPORARY`, `IF EXISTS`, `WAIT` / `NOWAIT`, `RESTRICT` / `CASCADE` options, metadata locks, atomic `DROP`, and replication behavior.

See INSERT.

Complete guide to inserting data in MariaDB. Complete `INSERT` syntax for single rows, bulk operations, and `ON DUPLICATE KEY` handling for production use.

See OPTIMIZE TABLE.

Complete MariaDB performance optimization guide. Complete reference for query tuning, indexing strategies, and configuration improvements for production use.

See RENAME TABLE.

Change the name of one or more tables atomically. This command moves tables within or between databases while preserving their data and structure.

See REPAIR TABLE.

Repair corrupted tables. This statement fixes errors in tables for supported storage engines like MyISAM, Aria, and Archive.

See REPAIR VIEW.

Check and correct a view's algorithm. This statement is primarily used by upgrade scripts to ensure view definitions are compatible.

See REPLACE.

Insert or replace rows based on unique keys. This statement acts like `INSERT`, but if a duplicate key exists, it deletes the old row and inserts the new one.

See SHOW COLUMNS.

Complete guide to displaying table columns in MariaDB. Complete `SHOW COLUMNS` syntax with field types, keys, and filtering options for production use.

See SHOW CREATE TABLE.

Get the SQL statement to recreate a table. This statement shows the complete `CREATE TABLE` syntax, including column definitions and indexes.

See SHOW INDEX.

Complete `SHOW INDEX` reference: `SHOW INDEX FROM`` *tbl_name*` syntax, output fields, and `WHERE` / `LIKE` filters.

See TRUNCATE TABLE.

Complete `TRUNCATE TABLE` reference with `[WAIT n|NOWAIT]` syntax, InnoDB `FOREIGN KEY` constraints, implicit commit, and `AUTO_INCREMENT` reset.

See UPDATE.

Complete `UPDATE` statement guide for MariaDB. Complete syntax reference with `WHERE` conditions, `JOIN` operations, and multi-table updates for production use.

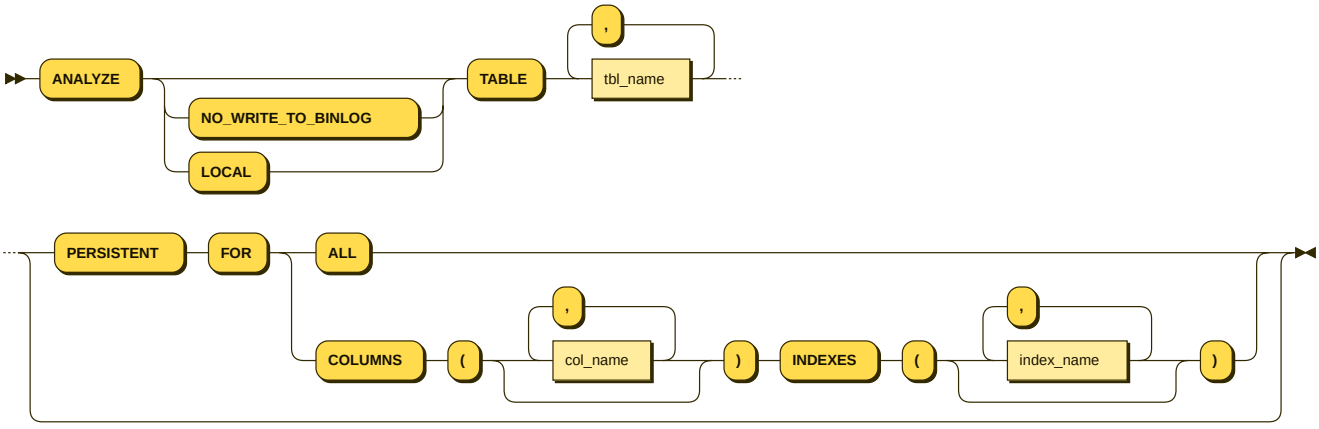
ANALYZE TABLE

Syntax

```
ANALYZE [NO_WRITE_TO_BINLOG | LOCAL] TABLE tbl_name [,tbl_name ...]
  [PERSISTENT FOR
    { ALL
      | COLUMNS ([col_name [,col_name ...]]) INDEXES ([index_name [,index_name ...]])
    }
  ]
```



Railroad diagram of ANALYZE TABLE — equivalent to the BNF above

Description

`ANALYZE TABLE` analyzes and stores the key distribution for a table (index statistics). This statement works with MyISAM, Aria, and InnoDB tables. During the analysis, InnoDB will allow reads/writes, and MyISAM/Aria reads/inserts. For MyISAM tables, this statement is equivalent to using myisamchk –analyze.

`ANALYZE` uses histograms, which can provide a better selectivity than InnoDB statistics offer. InnoDB statistics work with a limited sample set and are therefore not as accurate as persistent statistics can be. For more information on how the analysis works within InnoDB, see InnoDB Limitations.

MariaDB uses the stored key distribution to decide the order in which tables should be joined when you perform a join on something other than a constant. In addition, key distributions can be used when deciding which indexes to use for a specific table within a query.

This statement requires SELECT and INSERT privileges for the table.

By default, `ANALYZE TABLE` statements are written to the binary log and will be replicated. The `NO_WRITE_TO_BINLOG` keyword (`LOCAL` is an alias) will ensure the statement is not written to the binary log.

`ANALYZE TABLE` statements are not logged to the binary log if read_only is set. See also Read-Only Replicas.

> **CURRENT**
>
> `ANALYZE TABLE` is non-blocking and non-intrusive. A connection will start using new statistics for the query following the completion of the `ANALYZE TABLE`.
>
> **< 10.6.16**
>
> `ANALYZE TABLE` is blocking and intrusive.

`ANALYZE TABLE` is also supported for partitioned tables. You can use `ALTER TABLE ... ANALYZE PARTITION` to analyze one or more partitions.

The Aria storage engine supports progress reporting for the `ANALYZE TABLE` statement.

> **CURRENT**
>
> **Skipping Long CHAR/VARCHAR Columns**
>
> When using `ANALYZE TABLE PERSISTENT`, MariaDB skips long `CHAR` / `VARCHAR` columns during statistics collection if they exceed the value of the `analyze_max_length` system variable.
>
> This prevents excessive disk usage when analyzing tables with large text columns.
>
> - If a column is longer than `analyze_max_length`, it is excluded from stats.
> - If a long column is **explicitly specified** in `FOR COLUMNS()`, it is **still analyzed**, regardless of its size.
>
> Example:

```
SET GLOBAL analyze_max_length = 50000;
ANALYZE TABLE large_text_table PERSISTENT;
```

```
ANALYZE TABLE large_text_table PERSISTENT FOR COLUMNS(long_description);
```

```
CREATE TABLE product_data (
    id INT PRIMARY KEY,
    name VARCHAR(100),
    description VARCHAR(50000), -- long column
    specs VARCHAR(1000)
);

-- Set limit
SET SESSION analyze_max_length = 10000;

-- Run analysis without explicitly selecting columns
ANALYZE TABLE product_data PERSISTENT;

-- 'description' will be skipped due to length > 10000

-- To include it anyway
ANALYZE TABLE product_data PERSISTENT FOR COLUMNS(description);
```

> **< 10.6.23 / 10.11.14 / 11.4.8 / 11.8.3 / 12.0.2 / 12.1.1 / 11.8 ENTERPRISE SERVER**
>
> The functionality for skipping long `CHAR` and `VARCHAR` columns isn't available.

Performance Impact

Note that analyzing tables with `ANALYZE` can have a performance impact and can use a lot of disk space for big tables. As column statistics usually do not change much over time, even when the table grows, there is no benefit to running `ANALYZE` very often.

Running `ANALYZE` is indicated:

- for newly populated tables,
- for tables that have additional columns added that are used in WHERE clauses,
- when a table has doubled in size,
- when you note that a query becomes slow because the table order has changed, and you can see from EXPLAIN or ANALYZE FORMAT=JSON that the selectivity is wrong for a table,
- when the distribution of data in a table has changed significantly, for example, if you have loaded a batch of data or deleted a large amount of data.

> **Warning:**
>
> `ANALYZE` isn't useful for table columns of type `UNIQUE`, `PRIMARY KEY`, `TIME`, or `CURRENT_TIME`. In `ANALYZE` queries, you should omit columns of those types.

EITS Statistics / PERSISTENT FOR

Overview

`ANALYZE TABLE` supports engine-independent table statistics (EITS). See Engine-Independent Table Statistics: Collecting Statistics with the ANALYZE TABLE Statement for more information.

You can run the statement on all columns with this statement — however, be aware that this can take a long time for very large (500+ GB) tables:

```
ANALYZE TABLE tbl PERSISTENT FOR ALL
```

Focusing on particular columns, the statement looks like this — it collects statistics only for the specified table columns:

```
ANALYZE TABLE tbl PERSISTENT FOR COLUMNS (column1, column2, ...) INDEXES (index1, ...)
```

Focusing on columns helps, among other things, avoid including `BLOB` columns, for which MariaDB doesn't collect statistics.

> **Note:**
>
> It's recommended to collect statistics for columns that do *not* have an index starting from that column (if the index starts with a column, the index itself is used as a source for statistics), and which are used in `WHERE` conditions of your queries.

Queries That Benefit

Queries that benefit most are those where the query plan depends on the optimizer knowing condition selectivities, the most important ones being `JOIN` queries and those with an `ORDER BY ... LIMIT` clause. To benefit, the query must have a condition that may or may not be selective, for example:

```
SELECT *
FROM orders, customer
WHERE
       orders.o_custkey = customer.c_custkey  -- join condition
  AND  customer.c_area = 'EMEA'  -- (1)
  AND  orders.o_priority= 'URGENT' -- (2)
```

Here, the optimizer benefits from knowing these statistics:

1. Which fraction of customers are in the EMEA region?
2. Which fraction of orders are URGENT?

For that situation, you can issue this statement:

```
ANALYZE TABLE orders, customer PERSISTENT FOR ALL
```

EITS vs. InnoDB-Internal Statistics

EITS (engine-independent table statistics) provide way more data than InnoDB-internal statistics. The downside is that EITS are never automatically updated, and it takes time to collect them.

InnoDB statistics, on the other hand, provide less data, but they are automatically updated.

Controlling Statistics

Engine-independent statistics can be controlled (enabled and disabled) using the use_stat_tables variable and the optimizer_use_condition_selectivity variable. InnoDB-persistent statistics are controlled with the innodb_stats_persistent variable (allowing you to turn InnoDB statistics on or off). Combining both kinds of statistics is possible.

The server relies on InnoDB statistics by default. That way, it can use some statistics even if `ANALYZE TABLE` is never run (or not often enough). This gives good enough results for the majority of queries. Some queries, however, need more statistical data so the optimizer can create a good plan. Slow queries indicate there aren't enough statistical data. Those queries can be accelerated by running `ANALYZE TABLE tbl PERSISTENT FOR ...`, where `tbl` indicates a table used by a slow query. You can also run `ANALYZE TABLE ... PERSISTENT FOR ALL`, but that has a significant performance impact.

Useful Variables

The following overview indicates when a particular variable was introduced. When multiple versions are given, it means variable options (like the default value) changed between the indicated versions.

Variable	Introduced in MariaDB version	Description
analyze_max_length	MariaDB 10.6.23 / 10.11.14 / 11.4.8 / 11.8.3 / 12.0.2 / 12.1.1	Prevents the collection of column statistics for `CHAR` / `VARCHAR` columns that can be analyzed automatically by `ANALYZE TABLE PERSISTENT`. Columns exceeding this threshold in bytes will be skipped unless included explicitly in `FOR COLUMNS(...)`.
analyze_sample_percentage	10.4.3	Percentage of rows from the table ANALYZE TABLE will sample to collect table statistics. Set to 0 to let MariaDB decide what percentage of rows to sample.
histogram_type	10.4.3-11.0	Specifies the type of histograms created by ANALYZE. Options are #SINGLE_PREC_HB,DOUBLE_PREC_HB or JSON_HB.
histogram_size	10.7	Number of bytes or buckets (in case of JSON_HB) used for storing the histogram. If set to 0, no histograms are created by ANALYZE.]]

Variable	Introduced in MariaDB version	Description
log_slow_admin_statements	11.0.1	Log slow OPTIMIZE, ANALYZE, ALTER, and other administrative statements to the slow log if it is open. Deprecated. Use log_slow_filter instead.
log_slow_filter	(all versions)	Having an admin in the log_slow_filter will add slow ANALYZE_TABLE statements to the slow log.
sort_buffer_size	(all versions)	For calculating the number of duplicates, ANALYZE TABLE uses a buffer of sort_buffer_size bytes per column. You can slightly increase the speed of ANALYZE TABLE by increasing this variable.

Examples

```
-- update all engine-independent statistics for all columns and indexes
ANALYZE TABLE tbl PERSISTENT FOR ALL;

-- update specific columns and indexes:
ANALYZE TABLE tbl PERSISTENT FOR COLUMNS (col1,col2,...) INDEXES (idx1,idx2,...);

-- empty lists are allowed:
ANALYZE TABLE tbl PERSISTENT FOR COLUMNS (col1,col2,...) INDEXES ();
ANALYZE TABLE tbl PERSISTENT FOR COLUMNS () INDEXES (idx1,idx2,...);

-- the following will only update mysql.table_stats fields:
ANALYZE TABLE tbl PERSISTENT FOR COLUMNS () INDEXES ();

-- when use_stat_tables is set to 'COMPLEMENTARY' or 'PREFERABLY',
-- a simple ANALYZE TABLE  collects engine-independent statistics for all columns and indexes.
SET SESSION use_stat_tables='COMPLEMENTARY';
ANALYZE TABLE tbl;
```

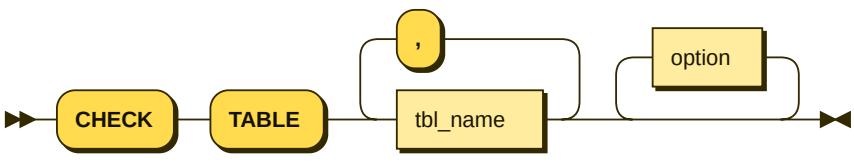
CHECK TABLE

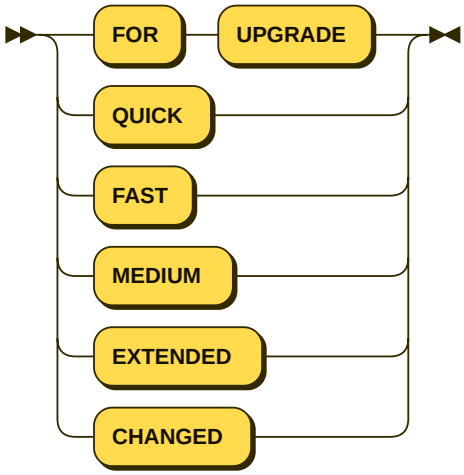
Syntax

```
CHECK TABLE tbl_name [, tbl_name] ... [option] ...

option = {FOR UPGRADE | QUICK | FAST | MEDIUM | EXTENDED | CHANGED}
```



Railroad diagram of CHECK TABLE



Railroad diagram of option

Description

`CHECK TABLE` checks a table or tables for errors. `CHECK TABLE` works for Archive, Aria, CSV, InnoDB, and MyISAM tables. For Aria and MyISAM tables, the key statistics are updated as well. For CSV, see also Checking and Repairing CSV Tables.

From MariaDB 12.0, `CHECK TABLE` also works on sequences. The sequence's underlying storage engine is checked first, then the sequence itself is validated.

As an alternative, myisamchk is a command-line tool for checking MyISAM tables when the tables are not being accessed. For Aria tables, there is a similar tool: aria_chk.

For checking dynamic columns' integrity, COLUMN_CHECK() can be used.

`CHECK TABLE` can also check views for problems, such as tables that are referenced in the view definition that no longer exist.

`CHECK TABLE` is also supported for partitioned tables. You can use `ALTER TABLE ... CHECK PARTITION` to check one or more partitions.

The meaning of the different options is as follows - note that this can vary a bit between storage engines:

Option	Explanation
FOR UPGRADE	Do a very quick check if the storage format for the table has changed so that one needs to do a `REPAIR`. This is only needed when one upgrades between major versions of MariaDB or MySQL. This is usually done by running mariadb-upgrade.
FAST	Only check tables that has not been closed properly or are marked as corrupt. Only supported by the MyISAM and Aria engines. For other engines the table is checked normally
CHANGED	Check only tables that have changed since the last `REPAIR` / `CHECK`. Only supported by the MyISAM and Aria engines. For other engines, the table is checked normally.
QUICK	Do a fast check. For MyISAM and Aria, this means skipping the check of the delete link chain, which may take some time.
MEDIUM	Scan also the data files. Checks the integrity between data and index files with checksums. In most cases, this should find all possible errors.
EXTENDED	Does a full check to verify every possible error. For InnoDB, Aria, and MyISAM, verify for each row that all its keys exist, and for those index keys, they point back to the primary clustered key. This may take a long time on large tables.

> **CURRENT**
>
> The `EXTENDED` option is available to InnoDB, too.
>
> **< 10.9.4 / 10.8.6 / 10.7.7 / 10.6.11**

> The `EXTENDED` option is ignored by InnoDB.

> **CURRENT**
>
> When the `EXTENDED` option is given, MariaDB also checks for referential integrity.
>
> **< 11.8**
>
> MariaDB does not check for referential integrity, even if the `EXTENDED` option is given.

For most cases, running `CHECK TABLE` without options or `MEDIUM` should be good enough.

The Aria storage engine supports progress reporting for this statement.

If you want to know if two tables are identical, take a look at CHECKSUM TABLE.

InnoDB

If `CHECK TABLE` finds an error in an InnoDB table, MariaDB might shut down to prevent the error propagation. In this case, the problem will be reported in the error log. Otherwise, the table or an index might be marked as corrupted, to prevent use. This does not happen with some minor problems, like a wrong number of entries in a secondary index. Those problems are reported in the output of `CHECK TABLE`.

Each tablespace contains a header with metadata. This header is not checked by this statement.

During the execution of `CHECK TABLE`, other threads may be blocked.

Examples

```
CHECK TABLE y EXTENDED;
+--------+-------+----------+----------+
| Table  | Op    | Msg_type | Msg_text |
+--------+-------+----------+----------+
| test.y | check | status   | OK       |
+--------+-------+----------+----------+
```

In newer MariaDB versions, the `EXTENDED` clause provides more information:

```
CHECK TABLE t1 EXTENDED;
+---------+-------+----------+-----------------------------------------------------------------------------+
| Table   | Op    | Msg_type | Msg_text                                                                    |
+---------+-------+----------+-----------------------------------------------------------------------------+
| test.t1 | check | Warning  | No suitable key found for foreign key t2_ibfk_1 in table test.t1    |
+---------+-------+----------+-----------------------------------------------------------------------------+

CHECK TABLE t2 EXTENDED;
+---------+-------+----------+-----------------------------------------------------------------------------------
----------------------+
| Table   | Op    | Msg_type | Msg_text
|
+---------+-------+----------+-----------------------------------------------------------------------------------
----------------------+
| test.t2 | check | status   | Cannot add or update a child row: a foreign key constraint fails (Key:
t2_ibfk_1, record: '2')  |
| test.t2 | check | status   | Cannot add or update a child row: a foreign key constraint fails (Key:
t2_ibfk_1, record: '2')  |
| test.t2 | check | status   | Cannot add or update a child row: a foreign key constraint fails (Key:
t2_ibfk_1, record: '3')  |
| test.t2 | check | error    | Corrupt
|
+---------+-------+----------+-----------------------------------------------------------------------------------
----------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

CHECK VIEW

Syntax

```
CHECK VIEW view_name
```

Description

The `CHECK VIEW` statement checks whether the view algorithm is correct. It is run as part of mariadb-upgrade, and should not normally be required in regular use.

See Also

- REPAIR VIEW

This page is licensed: CC BY-SA / Gnu FDL

CHECKSUM TABLE

Syntax

```
CHECKSUM TABLE tbl_name [, tbl_name] ... [ QUICK | EXTENDED ]
```

Description

`CHECKSUM TABLE` reports a table checksum. This is very useful if you want to know if two tables are the same (for example on a master and a replica).

With `QUICK`, the live table checksum is reported if it is available, or `NULL` otherwise. This is very fast. A live checksum is enabled by specifying the `CHECKSUM=1` table option when you create the table; currently, this is supported only for Aria and MyISAM tables.

With `EXTENDED`, the entire table is read row by row and the checksum is calculated. This can be very slow for large tables.

If neither `QUICK` nor `EXTENDED` is specified, MariaDB returns a live checksum if the table storage engine supports it and scans the table otherwise.

`CHECKSUM TABLE` requires the SELECT privilege for the table.

For a nonexistent table, `CHECKSUM TABLE` returns `NULL` and generates a warning.

The table row format affects the checksum value. If the row format changes, the checksum will change. This means that when a table created with a MariaDB/MySQL version is upgraded to another version, the checksum value will probably change.

Two identical tables should always match to the same checksum value; however, also for non-identical tables there is a very slight chance that they will return the same value as the hashing algorithm is not completely collision-free.

Identical Tables

Identical tables mean that the CREATE statement is identical and that the following variable, which affects the storage formats, was the same when the tables were created:

- mysql56-temporal-format

Differences Between MariaDB and MySQL

`CHECKSUM TABLE` may give a different result as MariaDB doesn't ignore `NULL`s in the columns like MySQL 5.1 does (later MySQL versions should calculate checksums the same way as MariaDB).

> **CURRENT**
>
> You can get the 'old style' checksum in MariaDB by setting old_mode to COMPAT_5_1_CHECKSUM. Note, however, that the MyISAM and Aria storage engines in MariaDB are using the new checksum internally, so if you are using this old mode, the `CHECKSUM` command will be slower as it needs to calculate the checksum row by row.
>
> **< 10.9**
>
> You can get the 'old style' checksum in MariaDB by starting mariadbd with the –old option. Note, however, that the MyISAM and Aria storage engines in MariaDB are using the new checksum internally, so if you are using this old mode, the `CHECKSUM` command will be slower as it needs to calculate the checksum row by row.

REPAIR TABLE

Syntax

> **CURRENT**
>
> ```
> REPAIR [NO_WRITE_TO_BINLOG | LOCAL] TABLE
>     tbl_name [, tbl_name] ...
>     [QUICK] [EXTENDED] [USE_FRM] [FORCE]
> ```
>
> >
>
> *Railroad diagram of REPAIR TABLE — equivalent to the BNF above*
>
> **< 11.5**
>
> ```
> REPAIR [NO_WRITE_TO_BINLOG | LOCAL] TABLE
>     tbl_name [, tbl_name] ...
>     [QUICK] [EXTENDED] [USE_FRM]
> ```

Description

`REPAIR TABLE` repairs a possibly corrupted table. By default, it has the same effect as

```
myisamchk --recover tbl_name
```

or

```
aria_chk --recover tbl_name
```

See aria_chk and myisamchk for more.

`REPAIR TABLE` works for Archive, Aria, CSV, and MyISAM tables. For InnoDB, see recovery modes. For CSV, see also Checking and Repairing CSV Tables. For Archive, this statement also improves compression. If the storage engine does not support this statement, a warning is issued.

This statement requires SELECT and INSERT privileges for the table.

By default, `REPAIR TABLE` statements are written to the binary log and will be replicated. The `NO_WRITE_TO_BINLOG` keyword (`LOCAL` is an alias) will ensure the statement is not written to the binary log.

> **CURRENT**
>
> `REPAIR TABLE` statements are not logged to the binary log if read_only is set. See also Read-Only Replicas.
>
> **< 10.3.19**
>
> `REPAIR TABLE` statements are logged to the binary log.

When an index is recreated, the storage engine may use a configurable buffer in the process. Incrementing the buffer speeds up the index creation. Aria and MyISAM allocate a buffer whose size is defined by aria_sort_buffer_size or myisam_sort_buffer_size, also used for ALTER TABLE.

QUICK

When specified, `REPAIR TABLE` will not modify the data file, only attempting to repair the index file. The same behavior can be achieved with myisamchk –recover –quick.

EXTENDED

Creates the index row by row rather than sorting and creating a single index. Similar to myisamchk –safe-recover.

USE_FRM

For use only when the index file is missing or its header corrupted. MariaDB then attempts to recreate it using the `.frm` file. There is no equivalent myisamchk option.

FORCE

> **CURRENT**
>
> The `FORCE` argument allows to first run internal repair to fix damaged blocks and then follow it up with `ALTER TABLE` (MDEV-33449).
>
> **< 11.5**
>
> The `FORCE` option is not available.

Partitioned Tables

`REPAIR TABLE` is also supported for partitioned tables with the ALTER TABLE … REPAIR PARTITION statement. However, the `USE_FRM` option cannot be used with this statement on a partitioned table. See Repairing Partitions for details.

Progress Reporting

The Aria storage engine supports progress reporting for this statement.

This page is licensed: GPLv2, originally from fill_help_tables.sql

REPAIR VIEW

Syntax

```
REPAIR [NO_WRITE_TO_BINLOG | LOCAL] VIEW  view_name[, view_name] ... [FROM MYSQL]
```

Description

The `REPAIR VIEW` statement checks whether the view algorithm is correct. It is run as part of mariadb-upgrade, and should not normally be required in regular use.

By default it corrects the checksum and if necessary adds the mariadb-version field. If the optional `FROM MYSQL` clause is used, and no mariadb-version field is present, the `MERGE` and `TEMPTABLE` algorithms are toggled.

By default, `REPAIR VIEW` statements are written to the binary log and will be replicated. The `NO_WRITE_TO_BINLOG` keyword (`LOCAL` is an alias) will ensure the statement is not written to the binary log.

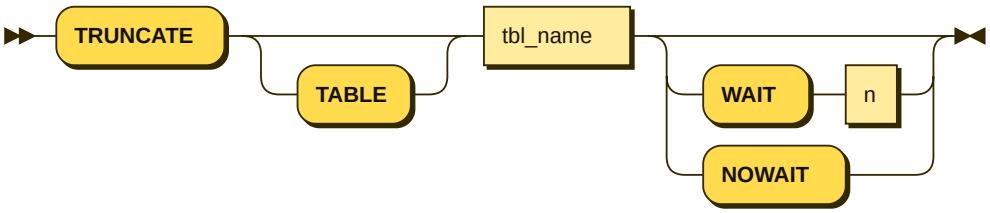
TRUNCATE TABLE

Syntax

```
TRUNCATE [TABLE] tbl_name
  [WAIT n | NOWAIT]
```



Railroad diagram of TRUNCATE TABLE — equivalent to the BNF above

Description

`TRUNCATE TABLE` empties a table completely. It requires the `DROP` privilege. See GRANT.

`tbl_name` can also be specified in the form `db_name.tbl_name` (see Identifier Qualifiers).

Logically, `TRUNCATE TABLE` is equivalent to a DELETE statement that deletes all rows, but there are practical differences under some circumstances.

`TRUNCATE TABLE` will fail for an InnoDB table if any FOREIGN KEY constraints from other tables reference the table, returning the error:

```
ERROR 1701 (42000): Cannot truncate a table referenced in a foreign key constraint
```

Foreign Key constraints between columns in the same table are permitted.

For an InnoDB table, if there are no `FOREIGN KEY` constraints, InnoDB performs fast truncation by dropping the original table and creating an empty one with the same definition, which is much faster than deleting rows one by one. The AUTO_INCREMENT counter is reset by `TRUNCATE TABLE`, regardless of whether there is a `FOREIGN KEY` constraint.

The count of rows affected by `TRUNCATE TABLE` is accurate only when it is mapped to a `DELETE` statement.

For other storage engines, `TRUNCATE TABLE` differs from `DELETE` in the following ways:

- Truncate operations drop and re-create the table, which is much faster than deleting rows one by one, particularly for large tables.
- Truncate operations cause an implicit commit.
- Truncation operations cannot be performed if the session holds an active table lock.
- Truncation operations do not return a meaningful value for the number of deleted rows. The usual result is "0 rows affected," which should be interpreted as "no information."
- As long as the table format file `tbl_name.frm` is valid, the table can be re-created as an empty table with `TRUNCATE TABLE`, even if the data or index files have become corrupted.
- The table handler does not remember the last used AUTO_INCREMENT value, but starts counting from the beginning. This is true even for MyISAM and InnoDB, which normally do not reuse sequence values.
- When used with partitioned tables, `TRUNCATE TABLE` preserves the partitioning; that is, the data and index files are dropped and re-created, while the partition definitions (.par) file is unaffected.
- Since truncation of a table does not make any use of `DELETE`, the `TRUNCATE` statement does not invoke `ON DELETE` triggers.
- `TRUNCATE TABLE` will only reset the values in the Performance Schema summary tables to zero or null, and will not remove the rows.

For the purposes of binary logging and replication, `TRUNCATE TABLE` is treated as DROP TABLE followed by CREATE TABLE (DDL rather than DML).

`TRUNCATE TABLE` does not work on views. It also cannot be used on a system-versioned table, returning the error:

```
ERROR 4137 (HY000): System-versioned tables do not support TRUNCATE TABLE
```

To remove historical records from a system-versioned table, use DELETE HISTORY instead.

WAIT/NOWAIT

Set the lock wait timeout. See WAIT and NOWAIT.

Oracle-mode

Oracle-mode permits the optional keywords `REUSE STORAGE` or `DROP STORAGE` to be used.

```
TRUNCATE [TABLE] tbl_name [{DROP | REUSE} STORAGE] [WAIT n | NOWAIT]
```

These have no effect on the operation.

Performance

`TRUNCATE TABLE` is faster than DELETE, because it drops and re-creates a table.

With InnoDB, `TRUNCATE TABLE` is slower if innodb_file_per_table=ON is set (the default). This is because `TRUNCATE TABLE` unlinks the underlying tablespace file, which can be an expensive operation. See MDEV-8069 for more details.

The performance issues with innodb_file_per_table=ON can be exacerbated in cases where the InnoDB buffer pool is very large and innodb_adaptive_hash_index=ON is set. In that case, using DROP TABLE followed by CREATE TABLE instead of `TRUNCATE TABLE` may perform better. Setting innodb_adaptive_hash_index=OFF can also help.

Setting innodb_adaptive_hash_index=OFF can also improve `TRUNCATE TABLE` performance in general. See MDEV-16796 for more details.

Transactions

See COMMIT.

Commit the current transaction. This statement permanently saves all changes made during the current transaction to the database.

See LOCK TABLES.

Complete LOCK TABLES reference: READ/WRITE/WRITE CONCURRENT lock syntax, table aliases, WAIT n|NOWAIT timeouts, UNLOCK TABLES, and innodb_table_locks behavior.

See Metadata Locking.

Understand how MariaDB manages concurrency. Metadata locks protect the structure of database objects from being modified while they are in use.

See READ COMMITTED.

Set the transaction isolation level to READ COMMITTED. In this mode, each query within a transaction sees only data committed before the query began.

See READ UNCOMMITTED.

Set the transaction isolation level to READ UNCOMMITTED. This lowest isolation level allows dirty reads, where a transaction can see uncommitted changes.

See REPEATABLE READ.

Set the transaction isolation level to REPEATABLE READ. This default InnoDB level ensures consistent results for repeated reads within the same transaction.

See ROLLBACK.

Undo changes in the current transaction. This statement reverts the database to its state before the transaction started or to a specific savepoint.

See SAVEPOINT.

Create a named marker within a transaction. Savepoints allow you to roll back part of a transaction without canceling the entire operation.

See SERIALIZABLE.

Set the transaction isolation level to SERIALIZABLE. This highest level ensures total isolation by converting plain SELECTs to locking reads.

See SQL statements Causing an Implicit Commit.

Identify statements that force a commit. Certain commands, like DDL statements, implicitly commit the current transaction before executing.

See START TRANSACTION.

Complete START TRANSACTION reference: BEGIN/COMMIT/ROLLBACK syntax, WITH CONSISTENT SNAPSHOT option, READ ONLY/WRITE modes, AND [NO] CHAIN/RELEASE modifiers.

See Transaction Timeouts.

Understand how timeouts affect transactions. This section explains system variables that control wait times for locks and transaction duration.

See UNLOCK TABLES.

Release explicit table locks. This statement releases all locks acquired by the current session with LOCK TABLES.

See WAIT and NOWAIT.

Control lock wait behavior. These clauses allow statements to wait for a specific timeout or fail immediately if a lock cannot be acquired.

See XA Transactions.

Manage distributed transactions. This section covers XA statements for coordinating two-phase commits across multiple resources.

This page is licensed: CC BY-SA / Gnu FDL

COMMIT

The `COMMIT` statement ends a transaction, saving any changes to the data so that they become visible to subsequent transactions. Also, unlocks metadata changed by current transaction. If autocommit is set to 1, an implicit commit is performed after each statement. Otherwise, all transactions which don't end with an explicit `COMMIT` are implicitly rollbacked and the changes are lost. The ROLLBACK statement can be used to do this explicitly.

The required syntax for the `COMMIT` statement is as follows:

```
COMMIT [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
```

`COMMIT` is the more important transaction terminator, as well as the more interesting one. The basic form of the `COMMIT` statement is simply the keyword `COMMIT` (the keyword `WORK` is simply noise and can be omitted without changing the effect).

The optional `AND CHAIN` clause is a convenience for initiating a new transaction as soon as the old transaction terminates. If `AND CHAIN` is specified, then there is effectively nothing between the old and new transactions, although they remain separate. The characteristics of the new transaction will be the same as the characteristics of the old one — that is, the new transaction will have the same access mode, isolation level and diagnostics area size (we'll discuss all of these shortly) as the transaction just terminated.

`RELEASE` tells the server to disconnect the client immediately after the current transaction.

There are `NO RELEASE` and `AND NO CHAIN` options. By default, commits do not `RELEASE` or `CHAIN`, but it's possible to change this default behavior with the completion_type server system variable. In this case, the `AND NO CHAIN` and `NO RELEASE` options override the server default.

See Also

- autocommit - server system variable that determines whether statements are automatically committed.
- completion_type - server system variable that determines whether COMMIT's are standard, COMMIT AND CHAIN or COMMIT RELEASE.
- SQL statements that cause an implicit commit

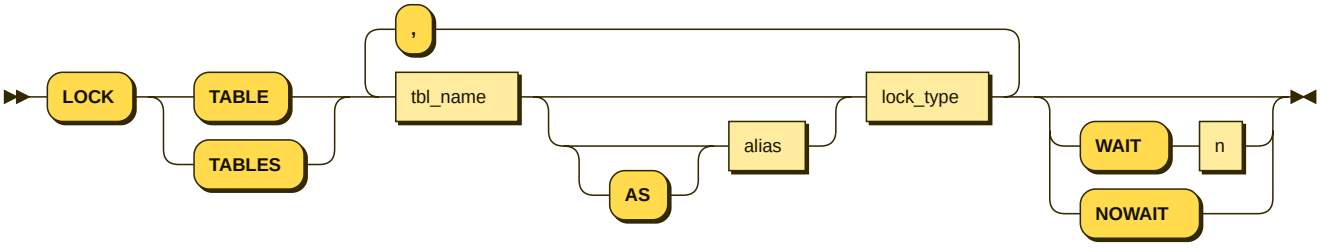
LOCK TABLES

Syntax

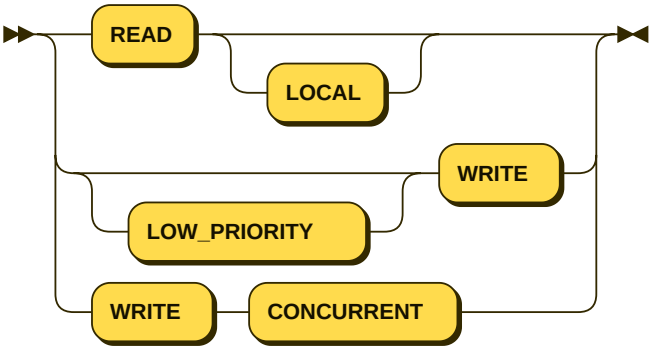
```
LOCK TABLE[S]
    tbl_name [[AS] alias] lock_type
    [, tbl_name [[AS] alias] lock_type] ...
    [WAIT n|NOWAIT]

lock_type:
    READ [LOCAL]
  | [LOW_PRIORITY] WRITE
  | WRITE CONCURRENT

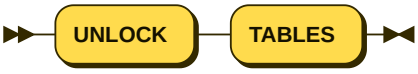
UNLOCK TABLES
```



Railroad diagram of LOCK TABLES



Railroad diagram of lock_type



Railroad diagram of UNLOCK TABLES

Description

The *lock_type* can be one of:

Option	Description
READ	Read lock, no writes allowed
READ LOCAL	Read lock, but allow concurrent inserts

Option	Description
WRITE	Exclusive write lock. No other connections can read or write to this table
LOW_PRIORITY WRITE	Exclusive write lock, but allow new read locks on the table until we get the write lock.
WRITE CONCURRENT	Exclusive write lock, but allow READ LOCAL locks to the table.

MariaDB enables client sessions to acquire table locks explicitly for the purpose of cooperating with other sessions for access to tables, or to prevent other sessions from modifying tables during periods when a session requires exclusive access to them. A session can acquire or release locks only for itself. One session cannot acquire locks for another session or release locks held by another session.

Locks may be used to emulate transactions or to get more speed when updating tables.

`LOCK TABLES` explicitly acquires table locks for the current client session. Table locks can be acquired for base tables or views. To use `LOCK TABLES`, you must have the `LOCK TABLES` privilege, and the `SELECT` privilege for each object to be locked. See GRANT.

For view locking, `LOCK TABLES` adds all base tables used in the view to the set of tables to be locked and locks them automatically. If you lock a table explicitly with `LOCK TABLES`, any tables used in triggers are also locked implicitly, as described in Triggers and Implicit Locks.

UNLOCK TABLES explicitly releases any table locks held by the current session.

Aliases

Aliases need to correspond to the aliases used in prior SQL statements in the session. For example:

```
LOCK TABLE t1 AS t1_alias1 READ;

SELECT * FROM t1;
ERROR 1100 (HY000): Table 't1' was not locked with LOCK TABLES

SELECT * FROM t1 AS t1_alias2;
ERROR 1100 (HY000): Table 't1_alias2' was not locked with LOCK TABLES

SELECT * FROM t1 AS t1_alias1;
```

WAIT/NOWAIT

Set the lock wait timeout. See WAIT and NOWAIT.

Limitations

- `LOCK TABLES` doesn't work when using Galera cluster. You may experience crashes or locks when used with Galera.
- `LOCK TABLES` works on XtraDB/InnoDB tables only if the innodb_table_locks system variable is set to 1 (the default) and autocommit is set to 0 (1 is default). Please note that no error message will be returned on LOCK TABLES with innodb_table_locks = 0.
- `LOCK TABLES` implicitly commits the active transaction, if any. Also, starting a transaction always releases all table locks acquired with LOCK TABLES. This means that there is no way to have table locks and an active transaction at the same time. The only exceptions are the transactions in autocommit mode. To preserve the data integrity between transactional and non-transactional tables, the GET_LOCK() function can be used.
- When using `LOCK TABLES` on a `TEMPORARY` table, it will always be locked with a `WRITE` lock.
- While a connection holds an explicit read lock on a table, it cannot modify it. If you try, the following error will be produced:

```
ERROR 1099 (HY000): Table 'tab_name' was locked with a READ lock and can't be updated
```

- While a connection holds an explicit lock on a table, it cannot access a non-locked table. If you try, the following error will be produced:

```
ERROR 1100 (HY000): Table 'tab_name' was not locked with LOCK TABLES
```

- While a connection holds an explicit lock on a table, it cannot issue the following: INSERT DELAYED, CREATE TABLE, CREATE TABLE … LIKE, and DDL statements involving stored programs and views (except for triggers). If you try, the following error will be produced:

```
ERROR 1192 (HY000): Can't execute the given command because you have active locked tables or an active
transaction
```

- `LOCK TABLES` can not be used in stored routines - if you try, the following error will be produced on creation:

```
ERROR 1314 (0A000): LOCK is not allowed in stored procedures
```

See Also

- UNLOCK TABLES

This page is licensed: GPLv2, originally from fill_help_tables.sql

Metadata Locking

MariaDB supports metadata locking. This means that when a transaction (including XA transactions) uses a table, it locks its metadata until the end of transaction. Non-transactional tables are also locked, as well as views and objects which are related to locked tables/views (stored functions, triggers, etc). When a connection tries to use a DDL statement (like an ALTER TABLE) which modifies a table that is locked, that connection is queued, and has to wait until it's unlocked. Using savepoints and performing a partial rollback does not release metadata locks.

LOCK TABLES … WRITE are also queued. Some wrong statements which produce an error may not need to wait for the lock to be freed.

The metadata lock's timeout is determined by the value of the lock_wait_timeout server system variable (in seconds). However, note that its default value is 31536000 (1 year). If this timeout is exceeded, the following error is returned:

```
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction
```

If the metadata_lock_info plugin is installed, the Information Schema metadata_lock_info table stores information about existing metadata locks.

CURRENT

The Performance Schema metadata_locks table contains metadata lock information.

Example

Let's use the following MEMORY (non-transactional) table:

```
CREATE TABLE t (a INT) ENGINE = MEMORY;
```

Connection 1 starts a transaction, and INSERTs a row into t:

```
START TRANSACTION;

INSERT INTO t SET a=1;
```

`t`'s metadata is now locked by connection 1. Connection 2 tries to alter `t`, but has to wait:

```
ALTER TABLE t ADD COLUMN b INT;
```

Connection 2's prompt is blocked now.

Now connection 1 ends the transaction:

```
COMMIT;
```

…and connection 2 finally gets the output of its command:

```
Query OK, 1 row affected (35.23 sec)
Records: 1  Duplicates: 0  Warnings: 0
```

< 10.5.2

The Performance Schema metadata_locks table does **not** contain metadata lock information.

This page is licensed: CC BY-SA / Gnu FDL

READ COMMITTED

`READ COMMITTED` is one of the transaction isolation levels. Each consistent read, even within the same transaction, sets and reads its own fresh snapshot.

See Isolation Levels for details.

This page is licensed: CC BY-SA / Gnu FDL

READ UNCOMMITTED

`READ UNCOMMITTED` is one of the transaction isolation levels. `SELECT` statements are performed in a non-locking fashion, but a possible earlier version of a row might be used.

See Isolation Levels for details.

This page is licensed: CC BY-SA / Gnu FDL

REPEATABLE READ

`REPEATABLE READ` is one of the transaction isolation levels. All consistent reads within the same transaction read the snapshot established by the first read.

See Isolation Levels for details.

This page is licensed: CC BY-SA / Gnu FDL

ROLLBACK

The `ROLLBACK` statement rolls back (ends) a transaction, destroying any changes to SQL-data so that they never become visible to subsequent transactions. The required syntax for the `ROLLBACK` statement is as follows.

```
ROLLBACK [ WORK ] [ AND [ NO ] CHAIN ]
[ TO [ SAVEPOINT ] {<savepoint name> | <simple target specification>} ]
```

The `ROLLBACK` statement will either end a transaction, destroying all data changes that happened during any of the transaction, or it will just destroy any data changes that happened since you established a savepoint. The basic form

of the `ROLLBACK` statement is just the keyword `ROLLBACK` (the keyword `WORK` is simply noise and can be omitted without changing the effect).

The optional `AND CHAIN` clause is a convenience for initiating a new transaction as soon as the old transaction terminates. If `AND CHAIN` is specified, then there is effectively nothing between the old and new transactions, although they remain separate. The characteristics of the new transaction will be the same as the characteristics of the old one — that is, the new transaction will have the same access mode, isolation level and diagnostics area size (we'll discuss all of these shortly) as the transaction just terminated. The `AND NO CHAIN` option just tells your DBMS to end the transaction — that is, these four SQL statements are equivalent:

```
ROLLBACK;
ROLLBACK WORK;
ROLLBACK AND NO CHAIN;
ROLLBACK WORK AND NO CHAIN;
```

All of them end a transaction without saving any transaction characteristics. The only other options, the equivalent statements …

```
ROLLBACK AND CHAIN;
ROLLBACK WORK AND CHAIN;
```

… both tell your DBMS to end a transaction, but to save that transaction's characteristics for the next transaction.

`ROLLBACK` is much simpler than `COMMIT`: it may involve no more than a few deletions (of Cursors, locks, prepared SQL statements and log-file entries). It's usually assumed that `ROLLBACK` can't fail, although such a thing is conceivable (for example, an encompassing transaction might reject an attempt to `ROLLBACK` because it's lining up for a `COMMIT`).

`ROLLBACK` cancels all effects of a transaction. It does not cancel effects on objects outside the DBMS's control (for example the values in host program variables or the settings made by some SQL/CLI function calls). But in general, it is a convenient statement for those situations when you say "oops, this isn't working" or when you simply don't care whether your temporary work becomes permanent or not.

Here is a moot question. If all you've been doing is `SELECT`s, so that there have been no data changes, should you end the transaction with `ROLLBACK` or `COMMIT`? It shouldn't really matter because both `ROLLBACK` and `COMMIT` do the same transaction-terminating job. However, the popular conception is that `ROLLBACK` implies failure, so after a successful series of `SELECT` statements the convention is to end the transaction with `COMMIT` rather than `ROLLBACK`.

MariaDB (and most other DBMSs) supports rollback of SQL-data change statements, but not of SQL-Schema statements. This means that if you use any of `CREATE`, `ALTER`, `DROP`, `GRANT`, `REVOKE`, you are implicitly committing at execution time.

```
INSERT INTO Table_2 VALUES(5);
DROP TABLE Table_3 CASCADE;
ROLLBACK;
```

The result will be that both the `INSERT` and the `DROP` will go through as separate transactions so the `ROLLBACK` will have no effect.

- Flashback, rollback transactions in binary log

This page is licensed: CC BY-SA / Gnu FDL

SAVEPOINT

Syntax

```
SAVEPOINT identifier
ROLLBACK [WORK] TO [SAVEPOINT] identifier
RELEASE SAVEPOINT identifier
```

Description

InnoDB supports the SQL statements `SAVEPOINT`, `ROLLBACK TO SAVEPOINT`, `RELEASE SAVEPOINT` and the optional `WORK` keyword for `ROLLBACK`.

Each savepoint must have a legal MariaDB identifier. A savepoint is a named sub-transaction.

Normally ROLLBACK undoes the changes performed by the whole transaction. When used with the `TO` clause, it undoes the changes performed after the specified savepoint, and erases all subsequent savepoints. However, all locks that have been acquired after the save point will survive. `RELEASE SAVEPOINT` does not rollback or commit any changes, but removes the specified savepoint.

When the execution of a trigger or a stored function begins, it is not possible to use statements which reference a savepoint which was defined from out of that stored program.

When a COMMIT (including implicit commits) or a `ROLLBACK` statement (with no `TO` clause) is performed, they act on the whole transaction, and all savepoints are removed.

Errors

If `COMMIT` or `ROLLBACK` is issued and no transaction was started, no error is reported.

If `SAVEPOINT` is issued and no transaction was started, no error is reported but no savepoint is created. When `ROLLBACK TO SAVEPOINT` or `RELEASE SAVEPOINT` is called for a savepoint that does not exist, an error like this is issued:

```
ERROR 1305 (42000): SAVEPOINT svp_name does not exist
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

SERIALIZABLE

`SERIALIZABLE` is one of the transaction isolation levels. Similar to `REPEATABLE READ`, but InnoDB implicitly converts all plain `SELECT` statements to `SELECT ... LOCK IN SHARE MODE` if autocommit is disabled.

See Isolation Levels for details.

This page is licensed: CC BY-SA / Gnu FDL

SQL statements Causing an Implicit Commit

Some SQL statements cause an implicit commit. As a rule of thumb, such statements are DDL statements. The same statements (except for SHUTDOWN) produce a 1400 error (SQLSTATE 'XAE09') if a XA transaction is in effect.

Here is the list:

```
ALTER DATABASE ... UPGRADE DATA DIRECTORY NAME
ALTER EVENT
ALTER FUNCTION
ALTER PROCEDURE
ALTER SEQUENCE
ALTER SERVER
ALTER TABLE
ALTER VIEW
ANALYZE TABLE
BEGIN
CACHE INDEX
CHANGE MASTER TO
CHECK TABLE
CREATE DATABASE
CREATE EVENT
CREATE FUNCTION
CREATE INDEX
CREATE PROCEDURE
CREATE ROLE
CREATE SEQUENCE
CREATE SERVER
CREATE TABLE
CREATE TRIGGER
CREATE USER
CREATE VIEW
DROP DATABASE
DROP EVENT
DROP FUNCTION
DROP INDEX
DROP PROCEDURE
DROP ROLE
DROP SEQUENCE
DROP SERVER
DROP TABLE
DROP TRIGGER
DROP USER
DROP VIEW
FLUSH
GRANT
LOAD INDEX INTO CACHE
LOCK TABLES
OPTIMIZE TABLE
RENAME TABLE
RENAME USER
REPAIR TABLE
RESET
REVOKE
SET PASSWORD
SHUTDOWN
START SLAVE
START TRANSACTION
STOP SLAVE
TRUNCATE TABLE
```

`SET autocommit = 1` causes an implicit commit if the value was 0.

All these statements cause an implicit commit before execution. This means that, even if the statement fails with an error, the transaction is committed. Some of them, like `CREATE TABLE ... SELECT`, also cause a commit immediately after execution. Such statements couldn't be rollbacked in any case.

If you are not sure whether a statement has implicitly committed the current transaction, you can query the in_transaction server system variable.

Note that when a transaction starts (not in autocommit mode), all locks acquired with LOCK TABLES are released. And acquiring such locks always commits the current transaction. To preserve the data integrity between transactional and non-transactional tables, the GET_LOCK() function can be used.

Exceptions

These statements do not cause an implicit commit in the following cases:

- CREATE TABLE and DROP TABLE, when the `TEMPORARY` keyword is used.
  - However, TRUNCATE TABLE causes an implicit commit even when used on a temporary table.
- CREATE FUNCTION and DROP FUNCTION, when used to create a UDF (instead of a stored function). However, CREATE INDEX and DROP INDEX cause commits even when used with temporary tables.
- UNLOCK TABLES causes a commit only if a LOCK TABLES was used on non-transactional tables.

This page is licensed: CC BY-SA / Gnu FDL

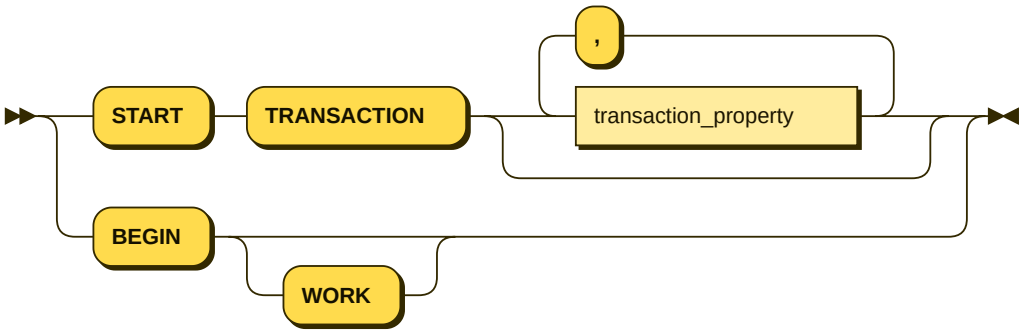
START TRANSACTION

Syntax

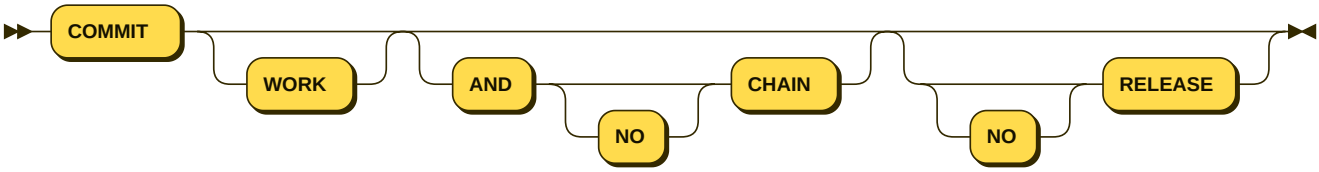
```
START TRANSACTION [transaction_property [, transaction_property] ...] | BEGIN [WORK]
COMMIT [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
ROLLBACK [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
SET autocommit = {0 | 1}

transaction_property:
    WITH CONSISTENT SNAPSHOT
  | READ WRITE
  | READ ONLY
```

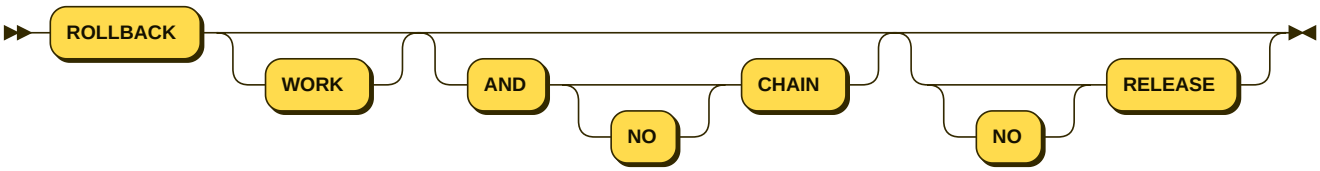
The BNF above documents four related statements together; each gets its own diagram below.



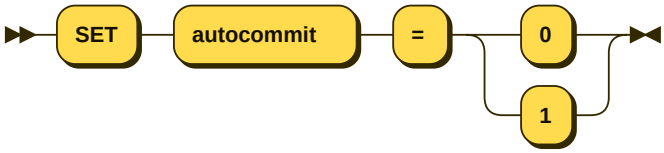
Railroad diagram of START TRANSACTION / BEGIN



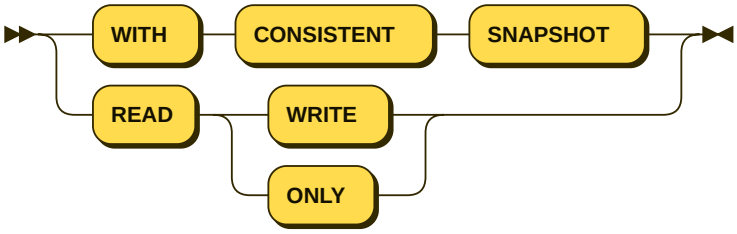
Railroad diagram of COMMIT



Railroad diagram of ROLLBACK



Railroad diagram of SET autocommit



Railroad diagram of transaction_property

Description

The `START TRANSACTION` or `BEGIN` statement begins a new transaction. COMMIT commits the current transaction, making its changes permanent. ROLLBACK rolls back the current transaction, canceling its changes. The SET autocommit statement disables or enables the default autocommit mode for the current session.

`START TRANSACTION` and `SET` autocommit = 1 implicitly commit the current transaction, if there is one.

The optional `WORK` keyword is supported for `COMMIT` and `ROLLBACK`, as are the `CHAIN` and `RELEASE` clauses. `CHAIN` and `RELEASE` can be used for additional control over transaction completion. The value of the completion_type system variable determines the default completion behavior.

The `AND CHAIN` clause causes a new transaction to begin as soon as the current one ends, and the new transaction has the same isolation level as the just-terminated transaction. The `RELEASE` clause causes the server to disconnect the current client session after terminating the current transaction. Including the `NO` keyword suppresses `CHAIN` or `RELEASE` completion, which can be useful if the completion_type system variable is set to cause chaining or release completion by default.

Access Mode

> **CURRENT**
>
> The access mode specifies whether the transaction is allowed to write data or not. By default, transactions are in `READ WRITE` mode (see the tx_read_only system variable). `READ ONLY` mode allows the storage engine to apply optimizations that cannot be used for transactions which write data. Note that, unlike the global read_only mode, the READ_ONLY ADMIN privilege doesn't allow writes and DDL statements on temporary tables are not allowed either.
>
> **< 10.11**
>
> The access mode specifies whether the transaction is allowed to write data or not. By default, transactions are in `READ WRITE` mode (see the tx_read_only system variable). `READ ONLY` mode allows the storage engine to apply optimizations that cannot be used for transactions which write data. Note that, unlike the global read_only mode, the SUPER privilege doesn't allow writes and DDL statements on temporary tables are not allowed either.

It is not permitted to specify both `READ WRITE` and `READ ONLY` in the same statement.

`READ WRITE` and `READ ONLY` can also be specified in the SET TRANSACTION statement, in which case the specified mode is valid for all sessions, or for all subsequent transaction used by the current session.

autocommit

By default, MariaDB runs with autocommit mode enabled. This means that as soon as you execute a statement that updates (modifies) a table, MariaDB stores the update on disk to make it permanent. To disable autocommit mode, use the following statement:

```
SET autocommit=0;
```

After disabling autocommit mode by setting the autocommit variable to zero, changes to transaction-safe tables (such as those for InnoDB or `NDBCLUSTER`) are not made permanent immediately. You must use `COMMIT` to store your changes to disk or `ROLLBACK` to ignore the changes.

To disable autocommit mode for a single series of statements, use the `START TRANSACTION` statement.

DDL Statements

DDL statements (`CREATE`, `ALTER`, `DROP`) and administrative statements (`FLUSH`, `RESET`, `OPTIMIZE`, `ANALYZE`, `CHECK`, `REPAIR`, `CACHE INDEX`), transaction management statements (`BEGIN`, `START TRANSACTION`) and `LOAD DATA INFILE`, cause an implicit `COMMIT` and start a new transaction. An exception to this rule are the DDL that operate on temporary tables: you can `CREATE`, `ALTER` and `DROP` them without causing any `COMMIT`, but those actions cannot be rolled back. This means that if you call `ROLLBACK`, the temporary tables you created in the transaction will remain, while the rest of the transaction will be rolled back.

Transactions cannot be used in Stored Functions or Triggers. In Stored Procedures and Events `BEGIN` is not allowed, so you should use `START TRANSACTION` instead.

A transaction acquires a metadata lock on every table it accesses to prevent other connections from altering their structure. The lock is released at the end of the transaction. This happens even with non-transactional storage engines (like MEMORY or CONNECT), so it makes sense to use transactions with non-transactional tables.

in_transaction

The in_transaction system variable is a session-only, read-only variable that returns `1` inside a transaction, and `0` if not in a transaction.

WITH CONSISTENT SNAPSHOT

The `WITH CONSISTENT SNAPSHOT` option starts a consistent read for storage engines such as InnoDB that can do so, the same as if a `START TRANSACTION` followed by a `SELECT` from any InnoDB table was issued.

See Enhancements for START TRANSACTION WITH CONSISTENT SNAPSHOT.

Examples

```
START TRANSACTION;
SELECT @A:=SUM(salary) FROM table1 WHERE type=1;
UPDATE table2 SET summary=@A WHERE type=1;
COMMIT;
```

- Enhancements for START TRANSACTION WITH CONSISTENT SNAPSHOT
- MyRocks and START TRANSACTION WITH CONSISTENT SNAPSHOT

This page is licensed: GPLv2, originally from fill_help_tables.sql

Transaction Timeouts

MariaDB has always had the wait_timeout and interactive_timeout settings, which close connections after a certain period of inactivity.

However, these are by default set to a long wait period. In situations where transactions may be started, but not committed or rolled back, more granular control and a shorter timeout may be desirable so as to avoid locks being held for too long.

> **CURRENT**
>
> These variables help handle this situation:
>
> - idle_transaction_timeout (all transactions)
> - idle_write_transaction_timeout (write transactions)
> - idle_readonly_transaction_timeout (read transactions)
>
> **< 10.3**
>
> There is no variables for more granular control.

These accept a time in seconds to time out, by closing the connection, transactions that are idle for longer than this period. By default all are set to zero, or no timeout.

idle_transaction_timeout affects all transactions, idle_write_transaction_timeout affects write transactions only and idle_readonly_transaction_timeout affects read transactions only. The latter two variables work independently. However, if either is set along with idle_transaction_timeout, the settings for idle_write_transaction_timeout or idle_readonly_transaction_timeout will take precedence.

Examples

```
SET SESSION idle_transaction_timeout=2;
BEGIN;
SELECT * FROM t;
Empty set (0.000 sec)
## wait 3 seconds
SELECT * FROM t;
ERROR 2006 (HY000): MySQL server has gone away
```

```
SET SESSION idle_write_transaction_timeout=2;
BEGIN;
SELECT * FROM t;
Empty set (0.000 sec)
## wait 3 seconds
SELECT * FROM t;
Empty set (0.000 sec)
INSERT INTO t VALUES(1);
## wait 3 seconds
SELECT * FROM t;
ERROR 2006 (HY000): MySQL server has gone away
```

```
SET SESSION idle_transaction_timeout=2, SESSION idle_readonly_transaction_timeout=10;
BEGIN;
SELECT * FROM t;
Empty set (0.000 sec)
 ## wait 3 seconds
SELECT * FROM t;
Empty set (0.000 sec)
## wait 11 seconds
SELECT * FROM t;
ERROR 2006 (HY000): MySQL server has gone away
```

This page is licensed: CC BY-SA / Gnu FDL

UNLOCK TABLES

Syntax

```
UNLOCK TABLES
```

Description

`UNLOCK TABLES` explicitly releases any table locks held by the current session. See LOCK TABLES for more information.

In addition to releasing table locks acquired by the LOCK TABLES statement, the `UNLOCK TABLES` statement also releases the global read lock acquired by the `FLUSH TABLES WITH READ LOCK` statement. The `FLUSH TABLES WITH READ LOCK` statement is very useful for performing backups. See FLUSH for more information about `FLUSH TABLES WITH READ LOCK`.

This page is licensed: CC BY-SA / Gnu FDL

WAIT and NOWAIT

Extended syntax so that it is possible to set innodb_lock_wait_timeout and lock_wait_timeout for the following statements:

Syntax

```
ALTER TABLE tbl_name [WAIT n|NOWAIT] ...
CREATE ... INDEX ON tbl_name (index_col_name, ...) [WAIT n|NOWAIT] ...
DROP INDEX ... [WAIT n|NOWAIT]
DROP TABLE tbl_name [WAIT n|NOWAIT] ...
LOCK TABLE ... [WAIT n|NOWAIT]
OPTIMIZE TABLE tbl_name [WAIT n|NOWAIT]
RENAME TABLE tbl_name [WAIT n|NOWAIT] ...
SELECT ... FOR UPDATE [WAIT n|NOWAIT]
SELECT ... LOCK IN SHARE MODE [WAIT n|NOWAIT]
TRUNCATE TABLE tbl_name [WAIT n|NOWAIT]
```

Description

The lock wait timeout can be explicitly set in the statement by using either `WAIT n` (to set the wait in seconds) or `NOWAIT`, in which case the statement will immediately fail if the lock cannot be obtained. `WAIT 0` is equivalent to `NOWAIT`.

XA Transactions

Overview

The MariaDB XA implementation is based on the X/Open CAE document Distributed Transaction Processing: The XA Specification. This document is published by The Open Group and available at c193.htm.

XA transactions are designed to allow distributed transactions, where a transaction manager (the application) controls a transaction which involves multiple resources. Such resources are usually DBMSs, but could be resources of any type. The whole set of required transactional operations is called a global transaction. Each subset of operations which involve a single resource is called a local transaction. XA used a 2-phases commit (2PC). With the first commit, the transaction manager tells each resource to prepare an effective commit, and waits for a confirm message. The changes are not still made effective at this point. If any of the resources encountered an error, the transaction manager will rollback the global transaction. If all resources communicate that the first commit is successful, the transaction manager can require a second commit, which makes the changes effective.

In MariaDB, XA transactions can only be used with storage engines that support them. At least InnoDB, SPIDER and MyRocks support them. XA transactions are always supported.

Like regular transactions, XA transactions create metadata locks on accessed tables.

XA transactions require REPEATABLE READ as a minimum isolation level. However, distributed transactions should always use SERIALIZABLE.

Trying to start more than one XA transaction at the same time produces a 1400 error (SQLSTATE 'XAE09'). The same error is produced when attempting to start an XA transaction while a regular transaction is in effect. Trying to start a regular transaction while an XA transaction is in effect produces a 1399 error (SQLSTATE 'XAE07').

The statements that cause an implicit COMMIT for regular transactions produce a 1400 error (SQLSTATE 'XAE09') if a XA transaction is in effect.

Internal XA vs External XA

XA transactions are an overloaded term in MariaDB. If a storage engine is XA-capable, it can mean one or both of these:

- It supports MariaDB's internal two-phase commit API. This is transparent to the user. Sometimes this is called "internal XA", since MariaDB's internal transaction coordinator log can handle coordinating these transactions.
- It supports XA transactions, with the `XA START`, `XA PREPARE`, `XA COMMIT`, etc. statements. Sometimes this is called "external XA", since it requires the use of an external transaction coordinator to use this feature properly.

Transaction Coordinator Log

If you have two or more XA-capable storage engines enabled, then a transaction coordinator log must be available.

There are currently two implementations of the transaction coordinator log:

- Binary log-based transaction coordinator log
- Memory-mapped file-based transaction coordinator log

If the binary log is enabled on a server, then the server will use the binary log-based transaction coordinator log. Otherwise, it will use the memory-mapped file-based transaction coordinator log.

See Transaction Coordinator Log for more information.

Syntax

```
XA {START|BEGIN} xid [JOIN|RESUME]

XA END xid [SUSPEND [FOR MIGRATE]]

XA PREPARE xid

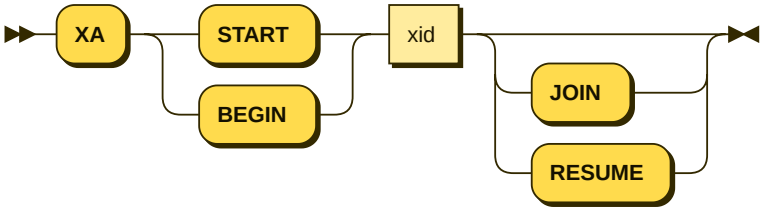
XA COMMIT xid [ONE PHASE]

XA ROLLBACK xid

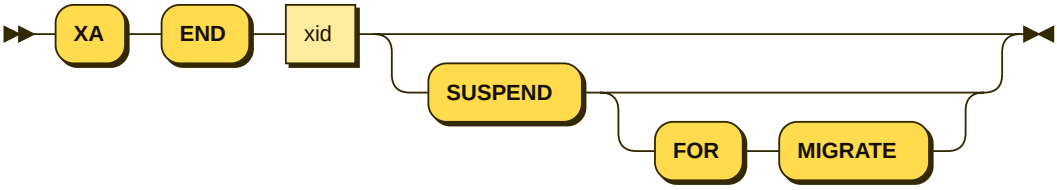
XA RECOVER [FORMAT=['RAW'|'SQL']]

xid: gtrid [, bqual [, formatID ]]
```

The BNF documents six XA statements together; each gets its own diagram.

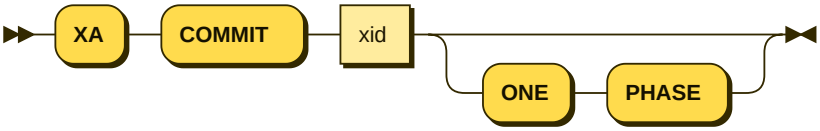


Railroad diagram of XA START / XA BEGIN



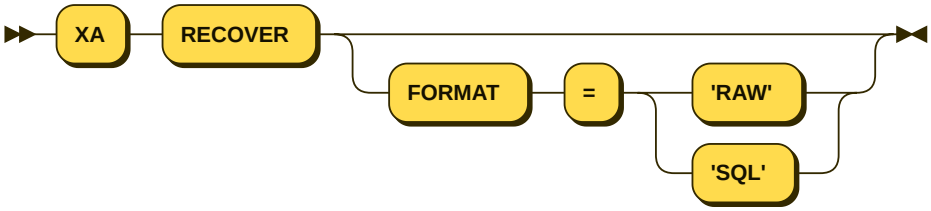
Railroad diagram of XA END

Railroad diagram of XA PREPARE

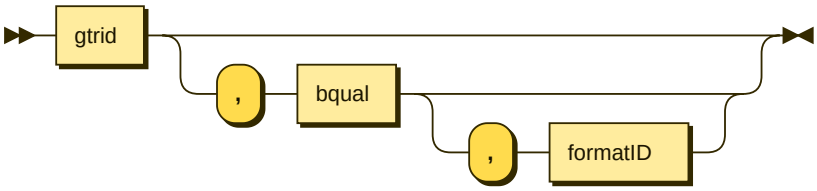


Railroad diagram of XA COMMIT

Railroad diagram of XA ROLLBACK



Railroad diagram of XA RECOVER



Railroad diagram of xid

The interface to XA transactions is a set of SQL statements starting with `XA`. Each statement changes a transaction's state, determining which actions it can perform. A transaction which does not exist is in the `NON-EXISTING` state.

When trying to execute an operation which is not allowed for the transaction's current state, an error is produced:

```
XA COMMIT 'test' ONE PHASE;
ERROR 1399 (XAE07): XAER_RMFAIL: The command cannot be executed when global transaction is in the  ACTIVE
state

XA COMMIT 'test2';
ERROR 1399 (XAE07): XAER_RMFAIL: The command cannot be executed when global transaction is in the  NON-
EXISTING state
```

XA START

```
XA {START|BEGIN} xid [JOIN|RESUME]
```

`XA START` (or `BEGIN`) starts a transaction and defines its `xid` (a transaction identifier). The new transaction will be in `ACTIVE` state.

The `xid` can have 3 components, though only the first one is mandatory. `gtrid` is a quoted string representing a global transaction identifier. `bqual` is a quoted string representing a local transaction identifier. `formatID` is an unsigned integer indicating the format used for the first two components; if not specified, defaults to 1. MariaDB does not interpret in any way these components, and only uses them to identify a transaction. `xid`s of transactions in effect must be unique.

Using the `JOIN` or `RESUME` keywords will currently cause an error to be returned.

```
XA START 'test' RESUME;
ERROR 1398 (XAE05): XAER_INVAL: Invalid arguments (or unsupported command)
XA START 'test' JOIN;
ERROR 1398 (XAE05): XAER_INVAL: Invalid arguments (or unsupported command)
```

An exception to this is that `XA START xid RESUME` will resume the transaction if the `xid` is the same as the previous `xid` used in `XA END xid`. This simply undoes the `XA END` and moves it from the `IDLE` state back into `ACTIVE`.

```
XA START 'test';
INSERT INTO t VALUES (1,2);
XA END 'test';
XA START 'test' RESUME; -- This reverts the XA END and continues the transaction
INSERT INTO t VALUES (3,4);
XA END 'test';
XA PREPARE 'test';
XA COMMIT 'test';
```

XA END

```
XA END xid [SUSPEND [FOR MIGRATE]]
```

`XA END` declares that the specified `ACTIVE` transaction is finished and it changes its state to `IDLE`. `SUSPEND [FOR MIGRATE]` has no effect.

XA PREPARE

```
XA PREPARE xid
```

`XA PREPARE` prepares an `IDLE` transaction for commit, changing its state to `PREPARED`. Prepared transactions are stored persistently and will survive disconnects and server crashes, and must be explicitly committed or rolled back.

> **CURRENT**
>
> Prepared transactions were automatically rolled back on client disconnect, but were not rolled back if the server was crashed or killed. This violated XA guarantees and could have caused inconsistent data, if the transaction in question was already irrevocably committed in another XA participant.
>
> **< 10.5**
>
> Prepared transactions are automatically rolled back on client disconnect, but are not rolled back if the server was crashed or killed. This violated XA guarantees and can cause inconsistent data, if the transaction in question was already irrevocably committed in another XA participant.

XA COMMIT

```
XA COMMIT xid [ONE PHASE]
```

`XA COMMIT` definitely commits and terminates a transaction which has already been `PREPARED`. If the `ONE PHASE` clause is specified, this statements performs a 1-phase commit on an `IDLE` transaction.

XA ROLLBACK

```
XA ROLLBACK xid
```

`XA ROLLBACK` rolls back and terminates an `IDLE` or `PREPARED` transaction.

XA RECOVER

```
XA RECOVER [FORMAT=['RAW'|'SQL']]
```

The `XA RECOVER` statement shows information about all transactions which are in the `PREPARED` state. It does not matter which connection created the transaction: if it has been `PREPARED`, it appears. But this does not mean that a connection can commit or rollback a transaction which was started by another connection. Note that transactions using a 1-phase commit are never in the `PREPARED` state, so they cannot be shown by `XA RECOVER`.

`XA RECOVER` produces four columns:

```
XA RECOVER;
+----------+--------------+--------------+------+
| formatID | gtrid_length | bqual_length | data |
+----------+--------------+--------------+------+
|        1 |            4 |            0 | test |
+----------+--------------+--------------+------+
```

You can use `XA RECOVER FORMAT='SQL'` to get the data in a human readable form that can be directly copy-pasted into `XA COMMIT` or `XA ROLLBACK`. This is particularly useful for binary `xid` generated by some transaction coordinators.

`formatID` is the `formatID` part of `xid`.

`data` are the `gtrid` and `bqual` parts of `xid`, concatenated.

`gtrid_length` and `bqual_length` are the lengths of `gtrid` and `bqual`, respectively.

Examples

2-phases commit:

```
XA START 'test';

INSERT INTO t VALUES (1,2);

XA END 'test';

XA PREPARE 'test';

XA COMMIT 'test';
```

1-phase commit:

```
XA START 'test';

INSERT INTO t VALUES (1,2);

XA END 'test';

XA COMMIT 'test' ONE PHASE;
```

Human-readable:

```
xa start '12\r34\t67\v78', 'abc\ndef', 3;

INSERT t1 values (40);

xa end '12\r34\t67\v78', 'abc\ndef', 3;

xa prepare '12\r34\t67\v78', 'abc\ndef', 3;

xa recover format='RAW';
+----------+--------------+--------------+--------------------+
| formatID | gtrid_length | bqual_length | data               |
+----------+--------------+--------------+--------------------+
34      67v78abc       11 |            7 | 12
def |
+----------+--------------+--------------+--------------------+

xa recover format='SQL';
+----------+--------------+--------------+-----------------------------------------------+
| formatID | gtrid_length | bqual_length | data                                          |
+----------+--------------+--------------+-----------------------------------------------+
|        3 |           11 |            7 | X'31320d3334093637763738',X'6162630a646566',3 |
+----------+--------------+--------------+-----------------------------------------------+

xa rollback X'31320d3334093637763738',X'6162630a646566',3;
```

Known Issues

MariaDB Galera Cluster

MariaDB Galera Cluster does not support XA transactions.

However, MariaDB Galera Cluster builds include a built-in plugin called `wsrep`. Consequently, these MariaDB Galera Cluster builds have multiple XA-capable storage engines by default, even if the only “real” storage engine that supports external XA transactions enabled on these builds by default is InnoDB. Therefore, when using one these builds MariaDB would be forced to use a transaction coordinator log by default, which could have performance implications.

See Transaction Coordinator Log Overview: MariaDB Galera Cluster for more information.

Incompatibility with XA behavior

> **Warning:**
>
> From MariaDB 10.5, `XA PREPARE` persists the XA transaction following the XA Specification. If an existing application relies on the previous behavior, upgrading to 10.5 or later can leave XA transactions in the `PREPARE`d state indefinitely after disconnect, causing such applications to no longer function correctly.

As a work-around, the variable legacy_xa_rollback_at_disconnect can be set to TRUE to re-enable the old behavior and roll back XA transactions in the `PREPARE`d state at disconnect. This is non-standard behaviour, and is not recommended for new applications. If rollback-at-disconnect is desired, it is better to use a normal (non-XA) transaction.

SQL Functions

See Functions & Operators.

Comprehensive reference of all SQL functions and operators. This index lists built-in functions for string manipulation, math, date/time, and more.

See Aggregate Functions.

Perform calculations on multiple rows to return a single value. Includes standard SQL functions like SUM, AVG, COUNT, MIN, and MAX, often used with GROUP BY.

See Control Flow Functions.

Learn about control flow functions in MariaDB Server. This section details SQL functions like IF, CASE, and NULLIF, which enable conditional logic within your queries and stored routines.

See Date & Time Functions.

Complete MariaDB date and time functions guide. Complete reference for formatting, calculations, conversions, time zones, and operations for production use.

See Numeric Functions.

Learn about numeric functions in MariaDB Server. This section details SQL functions for performing mathematical calculations, rounding, and manipulating numeric values in your queries.

See Pseudo Columns.

MariaDB has pseudo columns that can be used for different purposes.

See Secondary Functions.

Explore secondary functions in MariaDB Server. This section details various SQL functions that support specialized operations, enhancing data manipulation and analysis beyond core functionalities.

See Special Functions.

Explore special functions in MariaDB Server. This section details unique SQL functions that provide specialized capabilities, often related to server internals, diagnostics, or specific data handling.

See String Functions.

Learn about string functions in MariaDB Server. This section details SQL functions for manipulating, searching, and formatting text strings, essential for data cleansing and presentation.

See Vector Functions.

Explore vector functions. This section details SQL functions for manipulating and querying vector data types, enabling efficient similarity search and AI/ML applications within your database.

Functions & Operators

Name	Description	Added
+	Addition operator	
/	Division operator	
*	Multiplication operator	
%	Modulo operator. Returns the remainder of N divided by M	
-	Subtraction operator	
!=	Not equals	
<	Less than	
<=	Less than or equal	
<=>	NULL-safe equal	
=	Equal	
>	Greater than	
>=	Greater than or equal	
&	Bitwise AND	
<<	Shift left	
>>	Shift right	
^	Bitwise XOR	
!	Logical NOT	
&&	Logical AND	
XOR	Logical XOR	
|	Bitwise OR	
:=	Assignment operator	
=	Assignment and comparison operator	
~	Bitwise NOT	
ABS	Returns an absolute value	
ACOS	Returns an arc cosine	
ADD_MONTHS	Add months to a date	
ADDDATE	Add days or another interval to a date	
ADDTIME	Adds a time to a time or datetime	

Name	Description	Added
AES_DECRYPT	Decryption data encrypted with AES_ENCRYPT	
AES_ENCRYPT	Encrypts a string with the AES algorithm	
AREA	Synonym for ST_AREA	
AsBinary	Synonym for ST_AsBinary	
ASCII	Numeric ASCII value of leftmost character	
ASIN	Returns the arc sine	
AsText	Synonym for ST_AsText	
AsWKB	Synonym for ST_AsBinary	
AsWKT	Synonym for ST_AsText	
ATAN	Returns the arc tangent	
ATAN2	Returns the arc tangent of two variables	
AVG	Returns the average value	
BENCHMARK	Executes an expression repeatedly	
BETWEEN AND	True if expression between two values	
BIN	Returns binary value	
BINARY OPERATOR	Casts to a binary string	
BINLOG_GTID_POS	Returns a string representation of the corresponding GTID position	
BIT_AND	Bitwise AND	
BIT_COUNT	Returns the number of set bits	
BIT_LENGTH	Returns the length of a string in bits	
BIT_OR	Bitwise OR	
BIT_XOR	Bitwise XOR	
BOUNDARY	Synonym for ST_BOUNDARY	
BUFFER	Synonym for ST_BUFFER	
CASE	Returns the result where value=compare_value or for the first condition that is true	
CAST	Casts a value of one type to another type	
CEIL	Synonym for CEILING()	
CEILING	Returns the smallest integer not less than X	
CENTROID	Synonym for ST_CENTROID	
CHAR Function	Returns string based on the integer values for the individual characters	
CHARACTER_LENGTH	Synonym for CHAR_LENGTH()	
CHAR_LENGTH	Length of the string in characters	
CHARSET	Returns the character set	
CHR	Returns a string consisting of the character given by the code values of the integer	
COALESCE	Returns the first non-NULL parameter	
COERCIBILITY	Returns the collation coercibility value	
COLLATION	Collation of the string argument	

Name	Description	Added
COLUMN_ADD	Adds or updates dynamic columns	
COLUMN_CHECK	Checks if a dynamic column blob is valid	
COLUMN_CREATE	Returns a dynamic columns blob	
COLUMN_DELETE	Deletes a dynamic column	
COLUMN_EXISTS	Checks is a column exists	
COLUMN_GET	Gets a dynamic column value by name	
COLUMN_JSON	Returns a JSON representation of dynamic column blob data	
COLUMN_LIST	Returns comma-separated list	
COMPRESS	Returns a binary, compressed string	
CONCAT	Returns concatenated string	
CONCAT_WS	Concatenate with separator	
CONNECTION_ID	Connection thread ID	
CONTAINS	Whether one geometry contains another	
CONVERT	Convert a value from one type to another type	
CONV	Converts numbers between different number bases	
CONVERT_TZ	Converts a datetime from on time zone to another	
CONVEXHULL	Synonym for ST_CONVEXHULL	
COS	Returns the cosine	
COT	Returns the cotangent	
COUNT	Returns count of non-null values	
COUNT DISTINCT	Returns count of number of different non-NULL values	
CRC32	Computes a cyclic redundancy check value	
CRC32C	Computes a cyclic redundancy check value	MariaDB 10.8
CROSSES	Whether two geometries spatially cross	
CUME_DIST	Window function that returns the cumulative distribution of a given row	
CURDATE	Returns the current date	
CURRENT_DATE	Synonym for CURDATE()	
CURRENT_ROLE	Current role name	
CURRENT_TIME	Synonym for CURTIME()	
CURRENT_TIMESTAMP	Synonym for NOW()	
CURRENT_USER	Username/host that authenticated the current client	
CURTIME	Returns the current time	
DATABASE	Current default database	
DATE FUNCTION	Extracts the date portion of a datetime	
DATEDIFF	Difference in days between two date/time values	
DATE_ADD	Date arithmetic - addition	
DATE_FORMAT	Formats the date value according to the format string	
DATE_SUB	Date arithmetic - subtraction	
DAY	Synonym for DAYOFMONTH()	

Name	Description	Added
DAYNAME	Return the name of the weekday	
DAYOFMONTH	Returns the day of the month	
DAYOFWEEK	Returns the day of the week index	
DAYOFYEAR	Returns the day of the year	
DECODE	Decrypts a string encoded with ENCODE()	
DECODE_HISTOGRAM	Returns comma separated numerics corresponding to a probability distribution represented by a histogram	
DEFAULT	Returns column default	
DEGREES	Converts from radians to degrees	
DENSE_RANK	Rank of a given row with identical values receiving the same result, no skipping	
DES_DECRYPT	Decrypts a string encrypted with DES_ENCRYPT()	
DES_ENCRYPT	Encrypts a string using the Triple-DES algorithm	
DIMENSION	Synonym for ST_DIMENSION	
DISJOINT	Whether the two elements do not intersect	
DIV	Integer division	
ELT	Returns the N'th element from a set of strings	
ENCODE	Encrypts a string	
ENCRYPT	Encrypts a string with Unix crypt()	
ENDPOINT	Synonym for ST_ENDPOINT	
ENVELOPE	Synonym for ST_ENVELOPE	
EQUALS	Indicates whether two geometries are spatially equal	
EXP	e raised to the power of the argument	
EXPORT_SET	Returns an on string for every bit set, an off string for every bit not set	
ExteriorRing	Synonym for ST_ExteriorRing	
EXTRACT	Extracts a portion of the date	
EXTRACTVALUE	Returns the text of the first text node matched by the XPath expression	
FIELD	Returns the index position of a string in a list	
FIND_IN_SET	Returns the position of a string in a set of strings	
FLOOR	Largest integer value not greater than the argument	
FORMAT	Formats a number	
FORMAT_BYTES	Given a byte count, returns a string consisting of a value and the units in a human-readable format.	MariaDB 11.8
FORMAT_PICO_TIME	Given a time in picoseconds, returns a human-readable time value and unit indicator	MariaDB 11.0.2
FOUND_ROWS	Number of (potentially) returned rows	
FROM_BASE64	Given a base-64 encoded string, returns the decoded result as a binary string	
FROM_DAYS	Returns a date given a day	
FROM_UNIXTIME	Returns a datetime from a Unix timestamp	

Name	Description	Added
GeomCollFromText	Synonym for ST_GeomCollFromText	
GeomCollFromWKB	Synonym for ST_GeomCollFromWKB	
GEOMETRYCOLLECTION	Constructs a WKB GeometryCollection	
GeometryCollectionFromText	Synonym for ST_GeomCollFromText	
GeometryCollectionFromWKB	Synonym for ST_GeomCollFromWKB	
GeometryFromText	Synonym for ST_GeomFromText	
GeometryFromWKB	Synonym for ST_GeomFromWKB	
GeomFromText	Synonym for ST_GeomFromText	
GeomFromWKB	Synonym for ST_GeomFromWKB	
GeometryN	Synonym for ST_GeometryN	
GeometryType	Synonym for ST_GeometryType	
GET_FORMAT	Returns a format string	
GET_LOCK	Obtain LOCK	
GLENGTH	Length of a LineString value	
GREATEST	Returns the largest argument	
GROUP_CONCAT	Returns string with concatenated values from a group	
HEX	Returns hexadecimal value	
HOUR	Returns the hour	
IF	If expr1 is TRUE, returns expr2; otherwise returns expr3	
IFNULL	Check whether an expression is NULL	
IN	True if expression equals any of the values in the list	
INTERVAL	Index of the argument that is less than the first argument	
INET6_ATON	Given an IPv6 or IPv4 network address, returns a VARBINARY numeric value	
INET6_NTOA	Given an IPv6 or IPv4 network address, returns the address as a nonbinary string	
INET_ATON	Returns numeric value of IPv4 address	
INET_NTOA	Returns dotted-quad representation of IPv4 address	
INSERT Function	Replaces a part of a string with another string	
INSTR	Returns the position of a string within a string	
InteriorRingN	Synonym for ST_InteriorRingN	
INTERSECTS	Indicates whether two geometries spatially intersect	
IS	Tests whether a boolean is TRUE, FALSE, or UNKNOWN	
IsClosed	Synonym for ST_IsClosed	
IsEmpty	Synonym for ST_IsEmpty	
IS_FREE_LOCK	Checks whether lock is free to use	
IS_IPV4	Whether or not an expression is a valid IPv4 address	
IS_IPV4_COMPAT	Whether or not an IPv6 address is IPv4-compatible	

Name	Description	Added
IS_IPV4_MAPPED	Whether an IPv6 address is a valid IPv4-mapped address	
IS_IPV6	Whether or not an expression is a valid IPv6 address	
IS NOT	Tests whether a boolean value is not TRUE, FALSE, or UNKNOWN	
IS NOT NULL	Tests whether a value is not NULL	
IS NULL	Tests whether a value is NULL	
ISNULL	Checks if an expression is NULL	
IsRing	Synonym for ST_IsRing	
IsSimple	Synonym for ST_IsSimple	
IS_USED_LOCK	Check if lock is in use	
JSON_ARRAY	Returns a JSON array containing the listed values	
JSON_ARRAYAGG	Returns a JSON array containing an element for each value in a given set of JSON or SQL values.	
JSON_ARRAY_INTERSECT		MariaDB 11.2.0
JSON_ARRAY_APPEND	Appends values to the end of the given arrays within a JSON document	
JSON_ARRAY_INSERT	Inserts a value into a JSON document	
JSON_COMPACT	Removes all unnecessary spaces so the json document is as short as possible	
JSON_CONTAINS	Whether a value is found in a given JSON document or at a specified path within the document	
JSON_CONTAINS_PATH	Indicates whether the given JSON document contains data at the specified path or paths	
JSON_DEPTH	Maximum depth of a JSON document	
JSON_DETAILED	Represents JSON in the most understandable way emphasizing nested structures	
JSON_EQUALS	Check for equality between JSON objects.	MariaDB 10.7
JSON_EXISTS	Determines whether a specified JSON value exists in the given data	
JSON_EXTRACT	Extracts data from a JSON document.	
JSON_INSERT	Inserts data into a JSON document	
JSON_KEY_VALUE	Extracts key/value pairs from a JSON object	MariaDB 11.2
JSON_KEYS	Returns keys from top-level value of a JSON object or top-level keys from the path	
JSON_LENGTH	Returns the length of a JSON document, or the length of a value within the document	
JSON_LOOSE	Adds spaces to a JSON document to make it look more readable	
JSON_MERGE	Merges the given JSON documents	
JSON_MERGE_PATCH	RFC 7396-compliant merge of the given JSON documents	
JSON_MERGE_PRESERVE	Synonym for JSON_MERGE_PATCH.	

Name	Description	Added
JSON_NORMALIZE	Recursively sorts keys and removes spaces, allowing comparison of json documents for equality	
JSON_OBJECT	Returns a JSON object containing the given key/value pairs	
JSON_OBJECT_FILTER_KEYS		MariaDB 11.2.0
JSON_OBJECT_TO_ARRAY		MariaDB 11.2.0
JSON_OBJECTAGG	Returns a JSON object containing key-value pairs	
JSON_OVERLAPS	Compares two json documents for overlaps	MariaDB 10.9
JSON_PRETTY	Alias for json_detailed	MariaDB 10.10.3, MariaDB 10.9.5, MariaDB 10.8.7, MariaDB 10.7.8, MariaDB 10.6.12
JSON_QUERY	Given a JSON document, returns an object or array specified by the path	
JSON_QUOTE	Quotes a string as a JSON value	
JSON_REMOVE	Removes data from a JSON document	
JSON_REPLACE	Replaces existing values in a JSON document	
JSON_SCHEMA_VALID	Validates a JSON schema	MariaDB 11.1.0
JSON_SEARCH	Returns the path to the given string within a JSON document	
JSON_SET	Updates or inserts data into a JSON document	
JSON_TABLE	Returns a representation of a JSON document as a relational table	MariaDB 10.6
JSON_TYPE	Returns the type of a JSON value	
JSON_UNQUOTE	Unquotes a JSON value, returning a string	
JSON_VALID	Whether a value is a valid JSON document or not	
JSON_VALUE	Given a JSON document, returns the specified scalar	
KDF	Key derivation function	MariaDB 11.3.0
LAST_DAY	Returns the last day of the month	
LAST_INSERT_ID	Last inserted autoinc value	
LAST_VALUE	Returns the last value in a list	
LASTVAL	Get last value generated from a sequence	
LCASE	Synonym for [LOWER()	
LEAST	Returns the smallest argument	
LEFT	Returns the leftmost characters from a string	
LENGTH	Length of the string in bytes	
LIKE	Whether expression matches a pattern	
LineFromText	Synonym for ST_LineFromText	
LineFromWKB	Synonym for ST_LineFromWKB	
LINESTRING	Constructs a WKB LineString value from a number of WKB Point arguments	
LineStringFromText	Synonym for ST_LineFromText	
LineStringFromWKB	Synonym for ST_LineFromWKB	
LN	Returns natural logarithm	

Name	Description	Added
LOAD_FILE	Returns file contents as a string	
LOCALTIME	Synonym for NOW()	
LOCALTIMESTAMP	Synonym for NOW()	
LOCATE	Returns the position of a substring in a string	
LOG	Returns the natural logarithm	
LOG10	Returns the base-10 logarithm	
LOG2	Returns the base-2 logarithm	
LOWER	Returns a string with all characters changed to lowercase	
LPAD	Returns the string left-padded with another string to a given length	
LTRIM	Returns the string with leading space characters removed	
MAKE_SET	Make a set of strings that matches a bitmask	
MAKEDATE	Returns a date given a year and day	
MAKETIME	Returns a time	
MASTER_GTID_WAIT	Wait until slave reaches the GTID position	
MASTER_POS_WAIT	Blocks until the slave has applied all specified updates	
MATCH AGAINST	Perform a fulltext search on a fulltext index	
MAX	Returns the maximum value	
MBRContains	Whether one Minimum Bounding Rectangle contains another.	
MBRCoveredBy	Whether one Minimum Bounding Rectangle is covered by another.	MariaDB 11.8
MBRDisjoint	Whether the Minimum Bounding Rectangles of two geometries are disjoint	
MBREqual	Whether the Minimum Bounding Rectangles of two geometries are the same.	
MBREquals	Synonym for MBREqual.	
MBRIntersects	Indicates whether the Minimum Bounding Rectangles of the two geometries intersect	
MBROverlaps	Whether the Minimum Bounding Rectangles of two geometries overlap	
MBRTouches	Whether the Minimum Bounding Rectangles of two geometries touch.	
MBRWithin	Indicates whether one Minimum Bounding Rectangle is within another	
MD5	MD5 checksum	
MEDIAN	Window function that returns the median value of a range of values	
MICROSECOND	Returns microseconds from a date or datetime	
MID	Synonym for SUBSTRING(str,pos,len)	
MIN	Returns the minimum value	
MINUTE	Returns a minute from 0 to 59	
MLineFromText	Constructs MULTILINESTRING using its WKT representation and SRID	

Name	Description	Added
MLineFromWKB	Constructs a MULTILINESTRING	
MOD	Modulo operation. Remainder of N divided by M	
MONTH	Returns a month from 1 to 12	
MONTHNAME	Returns the full name of the month	
MPointFromText	Constructs a MULTIPOINT value using its WKT and SRID	
MPointFromWKB	Constructs a MULTIPOINT value using its WKB representation and SRID	
MPolyFromText	Constructs a MULTIPOLYGON value	
MPolyFromWKB	Constructs a MULTIPOLYGON value using its WKB representation and SRID	
MULTILINESTRING	Constructs a MultiLineString value	
MultiLineStringFromText	Synonym for MLineFromText	
MultiLineStringFromWKB	A synonym for MLineFromWKB	
MULTIPOINT	Constructs a WKB MultiPoint value	
MultiPointFromText	Synonym for MPointFromText	
MultiPointFromWKB	Synonym for MPointFromWKB	
MULTIPOLYGON	Constructs a WKB MultiPolygon	
MultiPolygonFromText	Synonym for MPolyFromText	
MultiPolygonFromWKB	Synonym for MPolyFromWKB	
NAME_CONST	Returns the given value	
NATURAL_SORT_KEY	Sorting that is more similar to natural human sorting	
NOT LIKE	Same as NOT(expr LIKE pat [ESCAPE ‘escape_char’])	
NOT REGEXP	Same as NOT (expr REGEXP pat)	
NULLIF	Returns NULL if expr1 = expr2	
NEXTVAL	Generate next value for sequence	
NOT BETWEEN	Same as NOT (expr BETWEEN min AND max)	
NOT IN	Same as NOT (expr IN (value,…))	
NOW	Returns the current date and time	
NTILE	Returns an integer indicating which group a given row falls into	
NumGeometries	Synonym for ST_NumGeometries	
NumInteriorRings	Synonym for NumInteriorRings	
NumPoints	Synonym for ST_NumPoints	
OCT	Returns octal value	
OCTET_LENGTH	Synonym for LENGTH()	
OLD_PASSWORD	Pre MySQL 4.1 password implementation	
ORD	Return ASCII or character code	
OVERLAPS	Indicates whether two elements spatially overlap	
PASSWORD	Calculates a password string	
PERCENT_RANK	Window function that returns the relative percent rank of a given row	

Name	Description	Added
PERCENTILE_CONT	Returns a value which corresponds to the given fraction in the sort order.	
PERCENTILE_DISC	Returns the first value in the set whose ordered position is the same or more than the specified fraction.	
PERIOD_ADD	Add months to a period	
PERIOD_DIFF	Number of months between two periods	
PI	Returns the value of π (pi)	
POINT	Constructs a WKB Point	
PointFromText	Synonym for ST_PointFromText	
PointFromWKB	Synonym for PointFromWKB	
PointN	Synonym for PointN	
PointOnSurface	Synonym for ST_PointOnSurface	
POLYGON	Constructs a WKB Polygon value from a number of WKB LineString arguments	
PolyFromText	Synonym for ST_PolyFromText	
PolyFromWKB	Synonym for ST_PolyFromWKB	
PolygonFromText	Synonym for ST_PolyFromText	
PolygonFromWKB	Synonym for ST_PolyFromWKB	
POSITION	Returns the position of a substring in a string	
POW	Returns X raised to the power of Y	
POWER	Synonym for POW()	
QUARTER	Returns year quarter from 1 to 4	
QUOTE	Returns quoted, properly escaped string	
RADIANS	Converts from degrees to radians	
RAND	Random floating-point value	
RANK	Rank of a given row with identical values receiving the same result	
REGEXP	Performs pattern matching	
REGEXP_INSTR	Position of the first appearance of a regex	
REGEXP_REPLACE	Replaces all occurrences of a pattern	
REGEXP_SUBSTR	Returns the matching part of a string	
RELEASE_LOCK	Releases lock obtained with GET_LOCK()	
REPEAT Function	Returns a string repeated a number of times	
REPLACE Function	Replace occurrences of a string	
REVERSE	Reverses the order of a string	
RIGHT	Returns the rightmost N characters from a string	
RLIKE	Synonym for REGEXP()	
RPAD	Returns the string right-padded with another string to a given length	
ROUND	Rounds a number	
ROW_COUNT	Number of rows affected by previous statement	

Name	Description	Added
ROW_NUMBER	Row number of a given row with identical values receiving a different result	
RTRIM	Returns the string with trailing space characters removed	
SCHEMA	Synonym for DATABASE()	
SECOND	Returns the second of a time	
SEC_TO_TIME	Converts a second to a time	
SETVAL	Set the next value to be returned by a sequence	
SESSION_USER	Synonym for USER()	
sha	Synonym for SHA1()	
SHA1	Calculates an SHA-1 checksum	
SHA2	Calculates an SHA-2 checksum	
SIGN	Returns 1, 0 or -1	
SIN	Returns the sine	
SLEEP	Pauses for the given number of seconds	
SOUNDEX	Returns a string based on how the string sounds	
SOUNDS LIKE	SOUNDEX(expr1) = SOUNDEX(expr2)	
SPACE	Returns a string of space characters	
SPIDER_BG_DIRECT_SQL	Background SQL execution	
SPIDER_COPY_TABLES	Copy table data	
SPIDER_DIRECT_SQL	Execute SQL on the remote server	
SPIDER_FLUSH_TABLE_MON_CACHE	Refreshing Spider monitoring server information	
SQRT	Square root	
SRID	Synonym for ST_SRID	
ST_AREA	Area of a Polygon	
ST_AsBinary	Converts a value to its WKB representation	
ST_AsGeoJson	Returns a GeoJSON element from a given geometry.	
ST_AsText	Converts a value to its WKT-Definition	
ST_AsWKB	Synonym for ST_AsBinary	
ST_ASWKT	Synonym for ST_ASTEXT()	
ST_BOUNDARY	Returns a geometry that is the closure of a combinatorial boundary	
ST_BUFFER	A new geometry with a buffer added to the original geometry	
ST_CENTROID	The mathematical centroid (geometric center) for a MultiPolygon	
ST_Collect	Returns the aggregation of the distinct geometry arguments	MariaDB 11.8
ST_CONTAINS	Whether one geometry is contained by another	
ST_CONVEXHULL	The minimum convex geometry enclosing all geometries within the set	
ST_CROSSES	Whether two geometries spatially cross	
ST_DIFFERENCE	Point set difference	

Name	Description	Added
ST_DIMENSION	Inherent dimension of a geometry value	
ST_DISJOINT	Whether one geometry is spatially disjoint from another	
ST_DISTANCE	The distance between two geometries	
ST_DISTANCE_SPHERE	The spherical distance between two geometries	
ST_ENDPOINT	Returns the endpoint of a LineString	
ST_ENVELOPE	Returns the Minimum Bounding Rectangle for a geometry value	
ST_EQUALS	Whether two geometries are spatoially equal	
ST_ExteriorRing	Returns the exterior ring of a Polygon as a LineString	
ST_GeoHash	Returns a geohash.	MariaDB 11.8
ST_GeomCollFromText	Constructs a GEOMETRYCOLLECTION value	
ST_GeomCollFromWKB	Constructs a GEOMETRYCOLLECTION value from a WKB	
ST_GeometryCollectionFromText	Synonym for ST_GeomCollFromText	
ST_GeometryCollectionFromWKB	Synonym for ST_GeomCollFromWKB	
ST_GeometryFromText	Synonym for ST_GeomFromText	
ST_GeometryFromWKB	Synonym for ST_GeomFromWKB	
ST_GEOMETRYN	Returns the N-th geometry in a GeometryCollection	
ST_GEOMETRYTYPE	Returns name of the geometry type of which a given geometry instance is a member	
ST_GeomFromGeoJSON	Returns a geometry object from a GeoJSON input	
ST_GeomFromText	Constructs a geometry value using its WKT and SRID	
ST_GeomFromWKB	Constructs a geometry value using its WKB representation and SRID	
ST_InteriorRingN	Returns the N-th interior ring for a Polygon	
ST_INTERSECTION	The intersection, or shared portion, of two geometries	
ST_INTERSECTS	Whether two geometries spatially intersect	
ST_ISCLOSED	Returns true if a given LINESTRING's start and end points are the same	
ST_ISEMPTY	Indicated validity of geometry value	
ST_IsRing	Returns true if a given LINESTRING is both ST_IsClosed and ST_IsSimple	
ST_IsSimple	Returns true if the given Geometry has no anomalous geometric points	
ST_IsValid	Returns 1 if the argument is geometrically valid, 0 if not.	MariaDB 11.8
ST_LatFromGeoHash	Returns a latitude from the given geohash.	MariaDB 11.8
ST_LongFromGeoHash	Returns a longitude from the given geohash.	MariaDB 11.8
ST_LENGTH	Length of a LineString value	
ST_LineFromText	Creates a linestring value	
ST_LineFromWKB	Constructs a LINESTRING using its WKB and SRID	
ST_LineStringFromText	Synonym for ST_LineFromText	

Name	Description	Added
ST_LineStringFromWKB	Synonym for ST_LineFromWKB	
ST_MLineFromText	Synonym for ST_GeomFromText	
ST_MLineFromWKB	Synonym for ST_GeomFromWKB	
ST_MPointFromText	Synonym for ST_GeomFromText	
ST_MPointFromWKB	Synonym for ST_GeomFromWKB	
ST_MPolyFromText	Synonym for ST_GeomFromText	
ST_MPolyFromWKB	Synonym for ST_GeomFromWKB	
ST_MultiLineStringFromText	Synonym for ST_GeomFromText	
ST_MultiLineStringFromWKB	Synonym for ST_GeomFromWKB	
ST_MultiPointFromText	Synonym for ST_GeomFromText	
ST_MultiPolygonFromText	Synonym for ST_GeomFromText	
ST_MultiPolygonFromWKB	Synonym for ST_GeomFromWKB	
ST_MultiPointFromWKB	Synonym for ST_GeomFromWKB	
ST_NUMGEOMETRIES	Number of geometries in a GeometryCollection	
ST_NumInteriorRings	Number of interior rings in a Polygon	
ST_NUMPOINTS	Returns the number of Point objects in a LineString	
ST_OVERLAPS	Whether two geometries overlap	
ST_PointFromGeoHash	Returns a point from the given geohash.	MariaDB 11.8
ST_PointFromText	Constructs a POINT value	
ST_PointFromWKB	Constructs POINT using its WKB and SRID	
ST_POINTN	Returns the N-th Point in the LineString	
ST_POINTONSURFACE	Returns a POINT guaranteed to intersect a surface	
ST_PolyFromText	Constructs a POLYGON value	
ST_PolyFromWKB	Constructs POLYGON value using its WKB representation and SRID	
ST_PolygonFromText	Synonym for ST_PolyFromText	
ST_PolygonFromWKB	Synonym for ST_PolyFromWKB	
ST_RELATE	Returns true if two geometries are related	
ST_Simplify	Applies the Ramer–Douglas–Peucker algorithm to provide generalized simplifications.	MariaDB 11.8
ST_SRID	Returns a Spatial Reference System ID	
ST_STARTPOINT	Returns the start point of a LineString	
ST_SYMDIFFERENCE	Portions of two geometries that don't intersect	
ST_TOUCHES	Whether one geometry g1 spatially touches another	
ST_UNION	Union of two geometries	
ST_Validate	Whether a geometry is compliant with the WKB format and SRID syntax, and is geometrically valid.	MariaDB 11.8
ST_WITHIN	Whether one geometry is within another	
ST_X	X-coordinate value for a point	

Name	Description	Added
ST_Y	Y-coordinate for a point	
STARTPOINT	Synonym for ST_StartPoint	
STD	Population standard deviation	
STDDEV	Population standard deviation	
STDDEV_POP	Returns the population standard deviation	
STDDEV_SAMP	Standard deviation	
STR_TO_DATE	Converts a string to date	
STRCMP	Compares two strings in sort order	
SUBDATE	Subtract a date unit or number of days	
SUBSTR	Returns a substring from string starting at a given position	
SUBSTRING	Returns a substring from string starting at a given position	
SUBSTRING_INDEX	Returns the substring from string before count occurrences of a delimiter	
SUBTIME	Subtracts a time from a date/time	
SUM	Sum total	
SYS.EXTRACT_SCHEMA_FROM_FILE_NAME	Given a file path, returns the schema (database) name	MariaDB 10.6
SYS.EXTRACT_TABLE_FROM_FILE_NAME	Given a file path, returns the table name	MariaDB 10.6
SYS.FORMAT_BYTES	Returns a string consisting of a value and the units in a human-readable format	MariaDB 10.6
SYS.FORMAT_PATH	Returns a modified path after replacing subpaths matching the values of various system variables with the variable name	MariaDB 10.6
SYS.FORMAT_STATEMENT	Returns a reduced length string	MariaDB 10.6
SYS.FORMAT_TIME	Returns a human-readable time value and unit indicator	MariaDB 10.6
SYS.LIST_ADD	Adds a value to a given list	MariaDB 10.6
SYS.LIST_DROP	Drops a value from a given list	MariaDB 10.6
SYS.PS_IS_ACCOUNT_ENABLED	Whether Performance Schema instrumentation for the given account is enabled	MariaDB 10.6
SYS.PS_IS_CONSUMER_ENABLED	Whether Performance Schema instrumentation for the given consumer is enabled	MariaDB 10.6
SYS.PS_IS_INSTRUMENT_DEFAULT_ENABLED	Whether a given Performance Schema instrument is enabled by default	MariaDB 10.6
SYS.PS_IS_INSTRUMENT_DEFAULT_TIMED	Returns whether a given Performance Schema instrument is timed by default	MariaDB 10.6
SYS.PS_IS_THREAD_INSTRUMENTED	Returns whether or not Performance Schema instrumentation for the given connection_id is enabled	MariaDB 10.6
SYS.PS_THREAD_ACCOUNT	Returns the account (username@hostname) associated with the given thread_id	MariaDB 10.6
SYS.PS_THREAD_ID	Returns the thread_id associated with the given connection_id	MariaDB 10.6
SYS.PS_THREAD_STACK	Returns all statements, stages, and events within the Performance Schema for a given thread_id	MariaDB 10.6

Name	Description	Added
SYS.PS_THREAD_TRX_INFO	Returns a JSON object with information about the thread specified by the given thread_id	MariaDB 10.6
SYS.QUOTE_IDENTIFIER	Quotes a string to produce a result that can be used as an identifier in an SQL statement	MariaDB 10.6
SYS.SYS_GET_CONFIG	Returns a configuration option value from the sys_config table	MariaDB 10.6
SYS.VERSION_MAJOR	Returns the MariaDB Server major release version	MariaDB 10.6
SYS.VERSION_MINOR	Returns the MariaDB Server minor release version	MariaDB 10.6
SYS.VERSION_PATCH	Returns the MariaDB Server patch release version	MariaDB 10.6
SYS_GUID	Generates a globally unique identifier	
SYSDATE	Returns the current date and time	
SYSTEM_USER	Synonym for USER()	
TAN	Returns the tangent	
TIME function	Extracts the time	
TIMEDIFF	Returns the difference between two date/times	
TIMESTAMP FUNCTION	Return the datetime, or add a time to a date/time	
TIMESTAMPADD	Add interval to a date or datetime	
TIMESTAMPDIFF	Difference between two datetimes	
TIME_FORMAT	Formats the time value according to the format string	
TIME_TO_SEC	Returns the time argument, converted to seconds	
TO_BASE64	Converts a string to its base-64 encoded form	
TO_CHAR	Converts a date/time type to a char	
TO_DAYS	Number of days since year 0	
TO_NUMBER	Converts and expression to NUMERIC	MariaDB 12.2
TO_SECONDS	Number of seconds since year 0	
TOUCHES	Whether two geometries spatially touch	
TRIM	Returns a string with all given prefixes or suffixes removed	
TRUNC	Returns a DATETIME truncated according to a given format.	MariaDB 12.2
TRUNCATE	Truncates X to D decimal places	
UCASE	Synonym for UPPER]]()	
UNHEX	Interprets pairs of hex digits as a number and converts to the character represented by the number	
UNCOMPRESS	Uncompresses string compressed with COMPRESS()	
UNCOMPRESSED_LENGTH	Returns length of a string before being compressed with COMPRESS()	
UNIX_TIMESTAMP	Returns a Unix timestamp	
UPDATEXML	Replace XML	
UPPER	Changes string to uppercase	
USER	Current user/host	
UTC_DATE	Returns the current UTC date	
UTC_TIME	Returns the current UTC time	
UTC_TIMESTAMP	Returns the current UTC date and time	

Name	Description	Added
UUID	Returns a Universal Unique Identifier v1	
UUIDv4	Returns a Universal Unique Identifier v4	MariaDB 11.7
UUIDv7	Returns a Universal Unique Identifier v7	MariaDB 11.7
UUID_SHORT	Return short universal identifier	
VALUES or VALUE	Refer to columns in INSERT … ON DUPLICATE KEY UPDATE	
VAR_POP	Population standard variance	
VAR_SAMP	Returns the sample variance	
VARIANCE	Population standard variance	
VEC_DISTANCE	Calculates either a Euclidean or Cosine distance between two vectors.	MariaDB 11.8
VEC_DISTANCE_COSINE	Calculates a Cosine distance between two vectors.	MariaDB 11.7
VEC_DISTANCE_EUCLIDEAN	Calculates a Euclidean (L2) distance between two points.	MariaDB 11.7
VEC_FromText	Converts a text representation of the vector to a vector.	MariaDB 11.6.0 Vector
VEC_ToText	Converts a binary vector into a json array of numbers (floats).	MariaDB 11.6.0 Vector
VERSION	MariaDB server version	
WEEK	Returns the week number	
WEEKDAY	Returns the weekday index	
WEEKOFYEAR	Returns the calendar week of the date as a number in the range from 1 to 53	
WEIGHT_STRING	Weight of the input string	
WITHIN	Indicate whether a geographic element is spacially within another	
WSREP_LAST_SEEN_GTID	Returns the Global Transaction ID of the most recent write transaction observed by the client.	
WSREP_LAST_WRITTEN_GTID	Returns the Global Transaction ID of the most recent write transaction performed by the client.	
WSREP_SYNC_WAIT_UPTO_GTID	Blocks the client until the transaction specified by the given Global Transaction ID is applied and committed by the node	
X	Synonym for ST_X	
Y	Synonym for ST_Y	
YEAR	Returns the year for the given date	
YEARWEEK	Returns year and week for a date

Aggregate Functions

See Stored Aggregate Functions.

Stored Aggregate Functions allow users to create custom aggregate functions that process a sequence of rows and return a single summary result. This page provides a general overview.

See AVG.

Calculate the average value. This function computes the arithmetic mean of a numeric expression, ignoring `NULL` values.

See BIT_AND.

Perform a bitwise `AND` operation. This function returns the result of performing a bitwise `AND` on all values in a given expression.

See BIT_OR.

Perform a bitwise `OR` operation. This function returns the result of performing a bitwise `OR` on all values in a given expression.

See BIT_XOR.

Perform a bitwise `XOR` operation. This function returns the result of performing a bitwise `XOR` on all values in a given expression.

See COUNT DISTINCT.

Count unique values. This function returns the number of distinct, non-`NULL` values found in the specified column or expression.

See COUNT.

Complete `COUNT()` function reference: `COUNT(*)` and `COUNT(expr)` syntax, `COUNT(DISTINCT)` usage, `GROUP BY` aggregation, and `OVER(PARTITION BY)` window syntax.

See GROUP_CONCAT.

Complete `GROUP_CONCAT` reference for MariaDB. Complete function guide with syntax, parameters, return values, and usage examples for production use.

See JSON_ARRAYAGG.

Aggregate values into a JSON array. This function aggregates a result set column into a single JSON array.

See JSON_OBJECTAGG.

Aggregate key-value pairs into a JSON object. This function aggregates two columns or expressions into a single JSON object.

See MAX.

Find the maximum value. This function returns the highest value in a set of values, applicable to numbers, strings, and dates.

See MIN.

Find the minimum value. This function returns the lowest value in a set of values, applicable to numbers, strings, and dates.

See STD.

Calculate population standard deviation. This function returns the square root of the population variance. It is a synonym for `STDDEV_POP()`.

See STDDEV.

Calculate population standard deviation. This function is a synonym for `STD()` and `STDDEV_POP()`, returning the square root of the population variance.

See STDDEV_POP.

Calculate population standard deviation. This function computes the standard deviation assuming the set of values represents the entire population.

See STDDEV_SAMP.

Calculate sample standard deviation. This function computes the standard deviation assuming the set of values represents a sample of the population.

See SUM.

Calculate the total sum. This function returns the sum of all values in a numeric expression, ignoring `NULL` values.

See VAR_POP.

Calculate population variance. This function computes the statistical variance for a set of values assumed to be the entire population.

See VAR_SAMP.

Calculate sample variance. This function computes the statistical variance for a set of values assumed to be a sample of the population.

See VARIANCE.

Calculate population variance. This function is a synonym for VAR_POP() and returns the variance of a set of values.

This page is licensed: CC BY-SA / Gnu FDL

AVG

Syntax

```
AVG([DISTINCT] expr)
```

Description

Returns the average value of expr. The DISTINCT option can be used to return the average of the distinct values of expr. NULL values are ignored. It is an aggregate function, and so can be used with the GROUP BY clause.

AVG() returns NULL if there were no matching rows.

AVG() can be used as a window function.

Examples

```
CREATE TABLE sales (sales_value INT);

INSERT INTO sales VALUES(10),(20),(20),(40);

SELECT AVG(sales_value) FROM sales;
+------------------+
| AVG(sales_value) |
+------------------+
|          22.5000 |
+------------------+

SELECT AVG(DISTINCT(sales_value)) FROM sales;
+---------------------------+
| AVG(DISTINCT(sales_value)) |
+---------------------------+
|                   23.3333 |
+---------------------------+
```

Commonly, AVG() is used with a GROUP BY clause:

```
CREATE TABLE student (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student VALUES
  ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
  ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
  ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
  ('Tatiana', 'SQL', 87), ('Tatiana', 'Tuning', 83);

SELECT name, AVG(score) FROM student GROUP BY name;
+---------+------------+
| name    | AVG(score) |
+---------+------------+
| Chun    |    74.0000 |
| Esben   |    37.0000 |
| Kaolin  |    72.0000 |
| Tatiana |    85.0000 |
+---------+------------+
```

Be careful to avoid this common mistake, not grouping correctly and returning mismatched data:

```
SELECT name,test,AVG(score) FROM student;
+------+------+------------+
| name | test | MIN(score) |
+------+------+------------+
| Chun | SQL  |         31 |
+------+------+------------+
```

As a window function:

```
CREATE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87), ('Tatiana', 'Tuning', 83);

SELECT name, test, score, AVG(score) OVER (PARTITION BY test)
    AS average_by_test FROM student_test;
+---------+--------+-------+-----------------+
| name    | test   | score | average_by_test |
+---------+--------+-------+-----------------+
| Chun    | SQL    |    75 |         65.2500 |
| Chun    | Tuning |    73 |         68.7500 |
| Esben   | SQL    |    43 |         65.2500 |
| Esben   | Tuning |    31 |         68.7500 |
| Kaolin  | SQL    |    56 |         65.2500 |
| Kaolin  | Tuning |    88 |         68.7500 |
| Tatiana | SQL    |    87 |         65.2500 |
| Tatiana | Tuning |    83 |         68.7500 |
+---------+--------+-------+-----------------+
```

BIT_AND

Syntax

```
BIT_AND(expr) [over_clause]
```

Description

Returns the bitwise AND of all bits in *expr*. The calculation is performed with 64-bit (BIGINT) precision. It is an aggregate function, and so can be used with the GROUP BY clause.

If no rows match, `BIT_AND` will return a value with all bits set to 1. NULL values have no effect on the result unless all results are NULL, which is treated as no match.

`BIT_AND` can be used as a window function with the addition of the *over_clause*.

Examples

```
CREATE TABLE vals (x INT);

INSERT INTO vals VALUES(111),(110),(100);

SELECT BIT_AND(x), BIT_OR(x), BIT_XOR(x) FROM vals;
+------------+-----------+------------+
| BIT_AND(x) | BIT_OR(x) | BIT_XOR(x) |
+------------+-----------+------------+
|        100 |       111 |        101 |
+------------+-----------+------------+
```

As an aggregate function:

```
CREATE TABLE vals2 (category VARCHAR(1), x INT);

INSERT INTO vals2 VALUES
  ('a',111),('a',110),('a',100),
  ('b','000'),('b',001),('b',011);

SELECT category, BIT_AND(x), BIT_OR(x), BIT_XOR(x)
  FROM vals GROUP BY category;
+----------+------------+-----------+------------+
| category | BIT_AND(x) | BIT_OR(x) | BIT_XOR(x) |
+----------+------------+-----------+------------+
| a        |        100 |       111 |        101 |
| b        |          0 |        11 |         10 |
+----------+------------+-----------+------------+
```

No match:

```
SELECT BIT_AND(NULL);
+----------------------+
| BIT_AND(NULL)        |
+----------------------+
| 18446744073709551615 |
+----------------------+
```

See Also

- BIT_OR
- BIT_XOR

This page is licensed: GPLv2, originally from fill_help_tables.sql

BIT_OR

Syntax

```
BIT_OR(expr) [over_clause]
```

Description

Returns the bitwise OR of all bits in `expr`. The calculation is performed with 64-bit (BIGINT) precision. It is an aggregate function, and so can be used with the GROUP BY clause.

If no rows match, `BIT_OR` will return a value with all bits set to `0`. NULL values have no effect on the result unless all results are NULL, which is treated as no match.

`BIT_OR` can be used as a window function with the addition of the *over_clause*.

Examples

```
CREATE TABLE vals (x INT);

INSERT INTO vals VALUES(111),(110),(100);

SELECT BIT_AND(x), BIT_OR(x), BIT_XOR(x) FROM vals;
+------------+-----------+------------+
| BIT_AND(x) | BIT_OR(x) | BIT_XOR(x) |
+------------+-----------+------------+
|        100 |       111 |        101 |
+------------+-----------+------------+
```

As an aggregate function:

```
CREATE TABLE vals2 (category VARCHAR(1), x INT);

INSERT INTO vals2 VALUES
  ('a',111),('a',110),('a',100),
  ('b','000'),('b',001),('b',011);

SELECT category, BIT_AND(x), BIT_OR(x), BIT_XOR(x)
  FROM vals GROUP BY category;
+----------+------------+-----------+------------+
| category | BIT_AND(x) | BIT_OR(x) | BIT_XOR(x) |
+----------+------------+-----------+------------+
| a        |        100 |       111 |        101 |
| b        |          0 |        11 |         10 |
+----------+------------+-----------+------------+
```

No match:

```
SELECT BIT_OR(NULL);
+--------------+
| BIT_OR(NULL) |
+--------------+
|            0 |
+--------------+
```

See Also

- BIT_AND
- BIT_XOR

This page is licensed: GPLv2, originally from fill_help_tables.sql

BIT_XOR

Syntax

```
BIT_XOR(expr) [over_clause]
```

Description

Returns the bitwise XOR of all bits in `expr`. The calculation is performed with 64-bit (BIGINT) precision. It is an aggregate function, and so can be used with the GROUP BY clause.

If no rows match, `BIT_XOR` will return a value with all bits set to `0`. NULL values have no effect on the result unless all results are NULL, which is treated as no match.

`BIT_XOR` can be used as a window function with the addition of the *over_clause*.

Examples

```
CREATE TABLE vals (x INT);

INSERT INTO vals VALUES(111),(110),(100);

SELECT BIT_AND(x), BIT_OR(x), BIT_XOR(x) FROM vals;
+------------+-----------+------------+
| BIT_AND(x) | BIT_OR(x) | BIT_XOR(x) |
+------------+-----------+------------+
|        100 |       111 |        101 |
+------------+-----------+------------+
```

As an aggregate function:

```
CREATE TABLE vals2 (category VARCHAR(1), x INT);

INSERT INTO vals2 VALUES
  ('a',111),('a',110),('a',100),
  ('b','000'),('b',001),('b',011);

SELECT category, BIT_AND(x), BIT_OR(x), BIT_XOR(x)
  FROM vals GROUP BY category;
+----------+------------+-----------+------------+
| category | BIT_AND(x) | BIT_OR(x) | BIT_XOR(x) |
+----------+------------+-----------+------------+
| a        |        100 |       111 |        101 |
| b        |          0 |        11 |         10 |
+----------+------------+-----------+------------+
```

No match:

```
SELECT BIT_XOR(NULL);
+---------------+
| BIT_XOR(NULL) |
+---------------+
|             0 |
+---------------+
```

See Also

- BIT_AND
- BIT_OR

This page is licensed: GPLv2, originally from fill_help_tables.sql

COUNT DISTINCT

Syntax

```
COUNT(DISTINCT expr,[expr...])
```

Description

Returns a count of the number of different non-NULL values.

COUNT(DISTINCT) returns 0 if there were no matching rows.

Examples

```
CREATE TABLE student (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student VALUES
  ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
  ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
  ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
  ('Tatiana', 'SQL', 87), ('Tatiana', 'Tuning', 83);

SELECT COUNT(*) FROM student;
+----------+
| COUNT(*) |
+----------+
|        8 |
+----------+

SELECT COUNT(DISTINCT (name)) FROM student;
+------------------------+
| COUNT(DISTINCT (name)) |
+------------------------+
|                      4 |
+------------------------+
```

See Also

- SELECT
- COUNT

This page is licensed: GPLv2, originally from fill_help_tables.sql

COUNT

Syntax

```
COUNT(expr)
```

Description

Returns a count of the number of non-NULL values of expr in the rows retrieved by a SELECT statement. The result is a BIGINT value. It is an aggregate function, and so can be used with the GROUP BY clause.

COUNT(*) counts the total number of rows in a table.

COUNT() returns 0 if there were no matching rows.

COUNT() can be used as a window function.

Examples

```
CREATE TABLE student (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student VALUES
  ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
  ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
  ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
  ('Tatiana', 'SQL', 87), ('Tatiana', 'Tuning', 83);

SELECT COUNT(*) FROM student;
+----------+
| COUNT(*) |
+----------+
|        8 |
+----------+
```

COUNT(DISTINCT) example:

```
SELECT COUNT(DISTINCT (name)) FROM student;
+------------------------+
| COUNT(DISTINCT (name)) |
+------------------------+
|                      4 |
+------------------------+
```

As a window function

```
CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87);

SELECT name, test, score, COUNT(score) OVER (PARTITION BY name)
    AS tests_written FROM student_test;
+---------+--------+-------+---------------+
| name    | test   | score | tests_written |
+---------+--------+-------+---------------+
| Chun    | SQL    |    75 |             2 |
| Chun    | Tuning |    73 |             2 |
| Esben   | SQL    |    43 |             2 |
| Esben   | Tuning |    31 |             2 |
| Kaolin  | SQL    |    56 |             2 |
| Kaolin  | Tuning |    88 |             2 |
| Tatiana | SQL    |    87 |             1 |
+---------+--------+-------+---------------+
```

GROUP_CONCAT

Syntax

```
GROUP_CONCAT(expr)
```

Description

This function returns a string result with the concatenated non-NULL values from a group. If any expr in GROUP_CONCAT evaluates to NULL, that tuple is not present in the list returned by GROUP_CONCAT.

It returns NULL if all arguments are NULL, or there are no matching rows.

The maximum returned length in bytes is determined by the group_concat_max_len server system variable, which defaults to 1M.

If group_concat_max_len <= 512, the return type is VARBINARY or VARCHAR; otherwise, the return type is BLOB or TEXT. The choice between binary or non-binary types depends from the input.

The full syntax is as follows:

```
GROUP_CONCAT([DISTINCT] expr [,expr ...]
             [ORDER BY {unsigned_integer | col_name | expr}
                 [ASC | DESC] [,col_name ...]]
             [SEPARATOR str_val]
             [LIMIT {[offset,] row_count | row_count OFFSET offset}])
```

`DISTINCT` eliminates duplicate values from the output string.

ORDER BY determines the order of returned values.

`SEPARATOR` specifies a separator between the values. The default separator is a comma (`,`). It is possible to avoid using a separator by specifying an empty string.

LIMIT

The LIMIT clause can be used with `GROUP_CONCAT`.

Examples

```
SELECT student_name,
       GROUP_CONCAT(test_score)
       FROM student
       GROUP BY student_name;
```

Get a readable list of MariaDB users from the mysql.user table:

```
SELECT GROUP_CONCAT(DISTINCT User ORDER BY User SEPARATOR '\n')
   FROM mysql.user;
```

In the former example, `DISTINCT` is used because the same user may occur more than once. The new line () used as a `SEPARATOR` makes the results easier to read.

Get a readable list of hosts from which each user can connect:

```
SELECT User, GROUP_CONCAT(Host ORDER BY Host SEPARATOR ', ')
   FROM mysql.user GROUP BY User ORDER BY User;
```

The former example shows the difference between the `GROUP_CONCAT`'s ORDER BY (which sorts the concatenated hosts), and the `SELECT`'s ORDER BY (which sorts the rows).

LIMIT can be used with `GROUP_CONCAT`, so, for example, given the following table:

```
CREATE TABLE d (dd DATE, cc INT);

INSERT INTO d VALUES ('2017-01-01',1);
INSERT INTO d VALUES ('2017-01-02',2);
INSERT INTO d VALUES ('2017-01-04',3);
```

the following query:

```
SELECT SUBSTRING_INDEX(GROUP_CONCAT(CONCAT_WS(":",dd,cc)
ORDER BY cc DESC),",",1) FROM d;
+-----------------------------------------------------------------------------+
| SUBSTRING_INDEX(GROUP_CONCAT(CONCAT_WS(":",dd,cc) ORDER BY cc DESC),",",1) |
+-----------------------------------------------------------------------------+
| 2017-01-04:3                                                                |
+-----------------------------------------------------------------------------+
```

can be more simply rewritten as:

```
SELECT GROUP_CONCAT(CONCAT_WS(":",dd,cc) ORDER BY cc DESC LIMIT 1) FROM d;
+-------------------------------------------------------------+
| GROUP_CONCAT(CONCAT_WS(":",dd,cc) ORDER BY cc DESC LIMIT 1) |
+-------------------------------------------------------------+
| 2017-01-04:3                                                |
+-------------------------------------------------------------+
```

NULLS:

```
CREATE OR REPLACE TABLE t1 (a int, b char);

INSERT INTO t1 VALUES (1, 'a'), (2, NULL);

SELECT GROUP_CONCAT(a, b) FROM t1;
+--------------------+
| GROUP_CONCAT(a, b) |
+--------------------+
| 1a                 |
+--------------------+
```

JSON_ARRAYAGG

> **Note:**
>
> `JSON_ARRAYAGG` is available from MariaDB 10.5.

Syntax

```
JSON_ARRAYAGG(column_or_expression)
```

Description

`JSON_ARRAYAGG` returns a JSON array containing an element for each value in a given set of JSON or SQL values. It acts on a column or an expression that evaluates to a single value.

The maximum returned length in bytes is determined by the group_concat_max_len server system variable.

Returns `NULL` in the case of an error, or if the result contains no rows.

`JSON_ARRAYAGG` cannot currently be used as a window function.

The full syntax is as follows:

```
JSON_ARRAYAGG([DISTINCT] expr
             [ORDER BY {unsigned_integer | col_name | expr}
                 [ASC | DESC] [,col_name ...]]
             [LIMIT {[offset,] row_count | row_count OFFSET offset}])
```

Examples

```
CREATE TABLE t1 (a INT, b INT);

INSERT INTO t1 VALUES (1, 1),(2, 1), (1, 1),(2, 1), (3, 2),(2, 2),(2, 2),(2, 2);

SELECT JSON_ARRAYAGG(a), JSON_ARRAYAGG(b) FROM t1;
+-------------------+-------------------+
| JSON_ARRAYAGG(a)  | JSON_ARRAYAGG(b)  |
+-------------------+-------------------+
| [1,2,1,2,3,2,2,2] | [1,1,1,1,2,2,2,2] |
+-------------------+-------------------+

SELECT JSON_ARRAYAGG(a), JSON_ARRAYAGG(b) FROM t1 GROUP BY b;
+------------------+------------------+
| JSON_ARRAYAGG(a) | JSON_ARRAYAGG(b) |
+------------------+------------------+
| [1,2,1,2]        | [1,1,1,1]        |
| [3,2,2,2]        | [2,2,2,2]        |
+------------------+------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

JSON_OBJECTAGG

Note:

`JSON_OBJECTAGG` is available from MariaDB 10.5.

Syntax

```
JSON_OBJECTAGG(key, value)
```

Description

`JSON_OBJECTAGG` returns a JSON object containing key-value pairs. It takes two expressions that evaluate to a single value, or two column names, as arguments, the first used as a key, and the second as a value.

The maximum returned length in bytes is determined by the group_concat_max_len server system variable.

Returns `NULL` in the case of an error, or if the result contains no rows.

`JSON_OBJECTAGG` cannot currently be used as a window function.

Examples

```
SELECT * FROM t1;
+------+-------+
| a    | b     |
+------+-------+
|    1 | Hello |
|    1 | World |
|    2 | This  |
+------+-------+

SELECT JSON_OBJECTAGG(a, b) FROM t1;
+----------------------------------------+
| JSON_OBJECTAGG(a, b)                   |
+----------------------------------------+
| {"1":"Hello", "1":"World", "2":"This"} |
+----------------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

MAX

Syntax

```
MAX([DISTINCT] expr)
```

Description

Returns the largest, or maximum, value of *`expr`*. `MAX()` can also take a string argument in which case it returns the maximum string value. The `DISTINCT` keyword can be used to find the maximum of the distinct values of *`expr`*, however, this produces the same result as omitting `DISTINCT`.

Note that SET and ENUM fields are currently compared by their string value rather than their relative position in the set, so MAX() may produce a different highest result than ORDER BY DESC.

It is an aggregate function, and so can be used with the GROUP BY clause.

MAX() can be used as a window function.

`MAX()` returns `NULL` if there were no matching rows.

> **CURRENT**
>
> Not only ascending, but also descending indexes can be used to optimize `MAX`.
>
> **< 11.4**
>
> Only ascending indexes can be used to optimize `MAX`.

Examples

```
CREATE TABLE student (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student VALUES
  ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
  ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
  ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
  ('Tatiana', 'SQL', 87), ('Tatiana', 'Tuning', 83);

SELECT name, MAX(score) FROM student GROUP BY name;
+---------+------------+
| name    | MAX(score) |
+---------+------------+
| Chun    |         75 |
| Esben   |         43 |
| Kaolin  |         88 |
| Tatiana |         87 |
+---------+------------+
```

`MAX` string:

```
SELECT MAX(name) FROM student;
+-----------+
| MAX(name) |
+-----------+
| Tatiana   |
+-----------+
```

Be careful to avoid this common mistake, not grouping correctly and returning mismatched data:

```
SELECT name,test,MAX(SCORE) FROM student;
+------+------+------------+
| name | test | MAX(SCORE) |
+------+------+------------+
| Chun | SQL  |         88 |
+------+------+------------+
```

Difference between `ORDER BY DESC` and `MAX()`:

```
CREATE TABLE student2(name CHAR(10),grade ENUM('b','c','a'));

INSERT INTO student2 VALUES('Chun','b'),('Esben','c'),('Kaolin','a');

SELECT MAX(grade) FROM student2;
+------------+
| MAX(grade) |
+------------+
| c          |
+------------+

SELECT grade FROM student2 ORDER BY grade DESC LIMIT 1;
+-------+
| grade |
+-------+
| a     |
+-------+
```

As a window function:

```
CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);
INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87);

SELECT name, test, score, MAX(score)
  OVER (PARTITION BY name) AS highest_score FROM student_test;
+---------+--------+-------+---------------+
| name    | test   | score | highest_score |
+---------+--------+-------+---------------+
| Chun    | SQL    |    75 |            75 |
| Chun    | Tuning |    73 |            75 |
| Esben   | SQL    |    43 |            43 |
| Esben   | Tuning |    31 |            43 |
| Kaolin  | SQL    |    56 |            88 |
| Kaolin  | Tuning |    88 |            88 |
| Tatiana | SQL    |    87 |            87 |
+---------+--------+-------+---------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

MIN

Syntax

```
MIN([DISTINCT] expr)
```

Description

Returns the minimum value of *expr*. `MIN()` may take a string argument, in which case it returns the minimum string value. The `DISTINCT` keyword can be used to find the minimum of the distinct values of *expr*, however, this produces the same result as omitting `DISTINCT`.

Note that SET and ENUM fields are currently compared by their string value rather than their relative position in the set, so MIN() may produce a different lowest result than ORDER BY ASC.

It is an aggregate function, and so can be used with the GROUP BY clause.

`MIN()` can be used as a window function.

`MIN()` returns `NULL` if there were no matching rows.

> **CURRENT**
>
> Not only ascending, but also descending indexes can be used to optimize `MIN`.
>
> **< 11.4**
>
> Only ascending indexes can be used to optimize `MIN`.

Examples

```
CREATE TABLE student (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student VALUES
  ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
  ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
  ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
  ('Tatiana', 'SQL', 87), ('Tatiana', 'Tuning', 83);

SELECT name, MIN(score) FROM student GROUP BY name;
+---------+------------+
| name    | MIN(score) |
+---------+------------+
| Chun    |         73 |
| Esben   |         31 |
| Kaolin  |         56 |
| Tatiana |         83 |
+---------+------------+
```

`MIN()` with a string:

```
SELECT MIN(name) FROM student;
+-----------+
| MIN(name) |
+-----------+
| Chun      |
+-----------+
```

Be careful to avoid this common mistake, not grouping correctly and returning mismatched data:

```
SELECT name,test,MIN(score) FROM student;
+------+------+------------+
| name | test | MIN(score) |
+------+------+------------+
| Chun | SQL  |         31 |
+------+------+------------+
```

Difference between `ORDER BY ASC` and `MIN()`:

```
CREATE TABLE student2(name CHAR(10),grade ENUM('b','c','a'));

INSERT INTO student2 VALUES('Chun','b'),('Esben','c'),('Kaolin','a');

SELECT MIN(grade) FROM student2;
+------------+
| MIN(grade) |
+------------+
| a          |
+------------+

SELECT grade FROM student2 ORDER BY grade ASC LIMIT 1;
+-------+
| grade |
+-------+
| b     |
+-------+
```

As a window function:

```
CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);
INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87);

SELECT name, test, score, MIN(score)
  OVER (PARTITION BY name) AS lowest_score FROM student_test;
+---------+--------+-------+--------------+
| name    | test   | score | lowest_score |
+---------+--------+-------+--------------+
| Chun    | SQL    |    75 |           73 |
| Chun    | Tuning |    73 |           73 |
| Esben   | SQL    |    43 |           31 |
| Esben   | Tuning |    31 |           31 |
| Kaolin  | SQL    |    56 |           56 |
| Kaolin  | Tuning |    88 |           56 |
| Tatiana | SQL    |    87 |           87 |
+---------+--------+-------+--------------+
```

See Also

- MAX (maximum)
- SUM (sum total)
- LEAST() returns the smallest value from a list.

This page is licensed: GPLv2, originally from fill_help_tables.sql

STD

Syntax

```
STD(expr)
```

Description

Returns the population standard deviation of `expr`. This is an extension to standard SQL. The standard SQL function STDDEV_POP() can be used instead.

It is an aggregate function, and so can be used with the GROUP BY clause.

`STD()` can be used as a window function.

This function returns `NULL` if there were no matching rows.

Examples

As an aggregate function:

```
CREATE OR REPLACE TABLE stats (category VARCHAR(2), x INT);

INSERT INTO stats VALUES
  ('a',1),('a',2),('a',3),
  ('b',11),('b',12),('b',20),('b',30),('b',60);

SELECT category, STDDEV_POP(x), STDDEV_SAMP(x), VAR_POP(x)
  FROM stats GROUP BY category;
+----------+--------------+----------------+------------+
| category | STDDEV_POP(x) | STDDEV_SAMP(x) | VAR_POP(x) |
+----------+--------------+----------------+------------+
| a        |        0.8165 |         1.0000 |     0.6667 |
| b        |       18.0400 |        20.1693 |   325.4400 |
+----------+--------------+----------------+------------+
```

As a window function:

```
CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87);

SELECT name, test, score, STDDEV_POP(score)
  OVER (PARTITION BY test) AS stddev_results FROM student_test;
+---------+--------+-------+----------------+
| name    | test   | score | stddev_results |
+---------+--------+-------+----------------+
| Chun    | SQL    |    75 |        16.9466 |
| Chun    | Tuning |    73 |        24.1247 |
| Esben   | SQL    |    43 |        16.9466 |
| Esben   | Tuning |    31 |        24.1247 |
| Kaolin  | SQL    |    56 |        16.9466 |
| Kaolin  | Tuning |    88 |        24.1247 |
| Tatiana | SQL    |    87 |        16.9466 |
+---------+--------+-------+----------------+
```

See Also

- STDDEV_POP (equivalent, standard SQL)
- STDDEV (equivalent, Oracle-compatible non-standard SQL)
- VAR_POP (variance)
- STDDEV_SAMP (sample standard deviation)

This page is licensed: GPLv2, originally from fill_help_tables.sql

STDDEV

Syntax

```
STDDEV(expr)
```

Description

Returns the population standard deviation of `expr`. This function is provided for compatibility with Oracle. The standard SQL function STDDEV_POP() can be used instead.

It is an aggregate function, and so can be used with the GROUP BY clause.

`STDDEV()` can be used as a window function.

This function returns `NULL` if there were no matching rows.

Examples

As an aggregate function:

```
CREATE OR REPLACE TABLE stats (category VARCHAR(2), x INT);

INSERT INTO stats VALUES
  ('a',1),('a',2),('a',3),
  ('b',11),('b',12),('b',20),('b',30),('b',60);

SELECT category, STDDEV_POP(x), STDDEV_SAMP(x), VAR_POP(x)
  FROM stats GROUP BY category;
+----------+---------------+----------------+------------+
| category | STDDEV_POP(x) | STDDEV_SAMP(x) | VAR_POP(x) |
+----------+---------------+----------------+------------+
| a        |        0.8165 |         1.0000 |     0.6667 |
| b        |       18.0400 |        20.1693 |   325.4400 |
+----------+---------------+----------------+------------+
```

As a window function:

```
CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87);

SELECT name, test, score, STDDEV_POP(score)
  OVER (PARTITION BY test) AS stddev_results FROM student_test;
+---------+--------+-------+----------------+
| name    | test   | score | stddev_results |
+---------+--------+-------+----------------+
| Chun    | SQL    |    75 |        16.9466 |
| Chun    | Tuning |    73 |        24.1247 |
| Esben   | SQL    |    43 |        16.9466 |
| Esben   | Tuning |    31 |        24.1247 |
| Kaolin  | SQL    |    56 |        16.9466 |
| Kaolin  | Tuning |    88 |        24.1247 |
| Tatiana | SQL    |    87 |        16.9466 |
+---------+--------+-------+----------------+
```

See Also

- STDDEV_POP (equivalent, standard SQL)
- STD (equivalent, non-standard SQL)
- VAR_POP (variance)
- STDDEV_SAMP (sample standard deviation)

This page is licensed: GPLv2, originally from fill_help_tables.sql

STDDEV_POP

Syntax

```
STDDEV_POP(expr)
```

Description

Returns the population standard deviation of *`expr`* (the square root of VAR_POP()). You can also use STD() or STDDEV(), which are equivalent but not standard SQL.

It is an aggregate function, and so can be used with the GROUP BY clause.

`STDDEV_POP()` can be used as a window function.

`STDDEV_POP()` returns `NULL` if there were no matching rows.

Examples

As an aggregate function:

```
CREATE OR REPLACE TABLE stats (category VARCHAR(2), x INT);

INSERT INTO stats VALUES
  ('a',1),('a',2),('a',3),
  ('b',11),('b',12),('b',20),('b',30),('b',60);

SELECT category, STDDEV_POP(x), STDDEV_SAMP(x), VAR_POP(x)
  FROM stats GROUP BY category;
+----------+---------------+----------------+------------+
| category | STDDEV_POP(x) | STDDEV_SAMP(x) | VAR_POP(x) |
+----------+---------------+----------------+------------+
| a        |        0.8165 |         1.0000 |     0.6667 |
| b        |       18.0400 |        20.1693 |   325.4400 |
+----------+---------------+----------------+------------+
```

As a window function:

```
CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87);

SELECT name, test, score, STDDEV_POP(score)
  OVER (PARTITION BY test) AS stddev_results FROM student_test;
+---------+--------+-------+----------------+
| name    | test   | score | stddev_results |
+---------+--------+-------+----------------+
| Chun    | SQL    |    75 |        16.9466 |
| Chun    | Tuning |    73 |        24.1247 |
| Esben   | SQL    |    43 |        16.9466 |
| Esben   | Tuning |    31 |        24.1247 |

- STD (equivalent, non-standard SQL)
- STDDEV (equivalent, Oracle-compatible non-standard SQL)
- VAR_POP (variance)
- STDDEV_SAMP (sample standard deviation)

This page is licensed: GPLv2, originally from fill_help_tables.sql

STDDEV_SAMP

Syntax

```
STDDEV_SAMP(expr)
```

Description

Returns the sample standard deviation of `expr` (the square root of VAR_SAMP()).

It is an aggregate function, and so can be used with the GROUP BY clause.

`STDDEV_SAMP()` can be used as a window function.

`STDDEV_SAMP()` returns `NULL` if there were no matching rows.

This page is licensed: GPLv2, originally from fill_help_tables.sql

SUM

Syntax

```
SUM([DISTINCT] expr)
```

Description

Returns the sum of *`expr`*. If the return set has no rows, `SUM()` returns `NULL`. The `DISTINCT` keyword can be used to sum only the distinct values of `expr`.

`SUM()` can be used as a window function, although not with the `DISTINCT` specifier.

Examples

```
CREATE TABLE sales (sales_value INT);
INSERT INTO sales VALUES(10),(20),(20),(40);

SELECT SUM(sales_value) FROM sales;
+------------------+
| SUM(sales_value) |
+------------------+
|               90 |
+------------------+

SELECT SUM(DISTINCT(sales_value)) FROM sales;
+----------------------------+
| SUM(DISTINCT(sales_value)) |
+----------------------------+
|                         70 |
+----------------------------+
```

Commonly, `SUM` is used with a GROUP BY clause:

```
CREATE TABLE sales (name CHAR(10), month CHAR(10), units INT);

INSERT INTO sales VALUES
  ('Chun', 'Jan', 75), ('Chun', 'Feb', 73),
  ('Esben', 'Jan', 43), ('Esben', 'Feb', 31),
  ('Kaolin', 'Jan', 56), ('Kaolin', 'Feb', 88),
  ('Tatiana', 'Jan', 87), ('Tatiana', 'Feb', 83);

SELECT name, SUM(units) FROM sales GROUP BY name;
+---------+------------+
| name    | SUM(units) |
+---------+------------+
| Chun    |        148 |
| Esben   |         74 |
| Kaolin  |        144 |
| Tatiana |        170 |
+---------+------------+
```

The GROUP BY clause is required when using an aggregate function along with regular column data, otherwise the result will be a mismatch, as in the following common type of mistake:

```
SELECT name,SUM(units) FROM sales
;+------+------------+
| name | SUM(units) |
+------+------------+
| Chun |        536 |
+------+------------+
```

As a window function:

```
CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);
INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87);

SELECT name, test, score, SUM(score) OVER (PARTITION BY name) AS total_score FROM student_test;
+---------+--------+-------+-------------+
| name    | test   | score | total_score |
+---------+--------+-------+-------------+
| Chun    | SQL    |    75 |         148 |
| Chun    | Tuning |    73 |         148 |
| Esben   | SQL    |    43 |          74 |
| Esben   | Tuning |    31 |          74 |
| Kaolin  | SQL    |    56 |         144 |
| Kaolin  | Tuning |    88 |         144 |
| Tatiana | SQL    |    87 |          87 |
+---------+--------+-------+-------------+
```

See Also

- AVG (average)
- MAX (maximum)
- MIN (minimum)

This page is licensed: GPLv2, originally from fill_help_tables.sql

VAR_POP

Syntax

```
VAR_POP(expr)
```

Description

Returns the population standard variance of `expr`. It considers rows as the whole population, not as a sample, so it has the number of rows as the denominator. You can also use VARIANCE(), which is equivalent but is not standard SQL.

Variance is calculated by

- working out the mean for the set;
- for each number, subtracting the mean and squaring the result;
- calculating the average of the resulting differences.

It is an aggregate function, and so can be used with the GROUP BY clause.

`VAR_POP()` can be used as a window function.

`VAR_POP()` returns `NULL` if there were no matching rows.

Examples

```
CREATE TABLE v(i tinyint);

INSERT INTO v VALUES(101),(99);

SELECT VAR_POP(i) FROM v;
+------------+
| VAR_POP(i) |
+------------+
|     1.0000 |
+------------+

INSERT INTO v VALUES(120),(80);

SELECT VAR_POP(i) FROM v;
+------------+
| VAR_POP(i) |
+------------+
|   200.5000 |
+------------+
```

As an aggregate function:

```
CREATE OR REPLACE TABLE stats (category VARCHAR(2), x INT);

INSERT INTO stats VALUES
  ('a',1),('a',2),('a',3),
  ('b',11),('b',12),('b',20),('b',30),('b',60);

SELECT category, STDDEV_POP(x), STDDEV_SAMP(x), VAR_POP(x)
  FROM stats GROUP BY category;
+----------+---------------+----------------+------------+
| category | STDDEV_POP(x) | STDDEV_SAMP(x) | VAR_POP(x) |
+----------+---------------+----------------+------------+
| a        |        0.8165 |         1.0000 |     0.6667 |
| b        |       18.0400 |        20.1693 |   325.4400 |
+----------+---------------+----------------+------------+
```

As a window function:

```
CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87);

SELECT name, test, score, VAR_POP(score)
  OVER (PARTITION BY test) AS variance_results FROM student_test;
+---------+--------+-------+------------------+
| name    | test   | score | variance_results |
+---------+--------+-------+------------------+
| Chun    | SQL    |    75 |         287.1875 |
| Esben   | SQL    |    43 |         287.1875 |
| Kaolin  | SQL    |    56 |         287.1875 |
| Tatiana | SQL    |    87 |         287.1875 |
| Chun    | Tuning |    73 |         582.0000 |
| Esben   | Tuning |    31 |         582.0000 |
| Kaolin  | Tuning |    88 |         582.0000 |
+---------+--------+-------+------------------+
```

See Also

- VARIANCE (equivalent, non-standard SQL)
- STDDEV_POP (population standard deviation)
- STDDEV_SAMP (sample standard deviation)

This page is licensed: GPLv2, originally from fill_help_tables.sql

VAR_SAMP

Syntax

```
VAR_SAMP(expr)
```

Description

Returns the sample variance of *`expr`*. That is, the denominator is the number of rows minus one.

It is an aggregate function, and so can be used with the GROUP BY clause.

VAR_SAMP() can be used as a window function.

VAR_SAMP() returns `NULL` if there were no matching rows.

Examples

As an aggregate function:

```
CREATE OR REPLACE TABLE stats (category VARCHAR(2), x INT);

INSERT INTO stats VALUES
  ('a',1),('a',2),('a',3),
  ('b',11),('b',12),('b',20),('b',30),('b',60);

SELECT category, STDDEV_POP(x), STDDEV_SAMP(x), VAR_POP(x)
  FROM stats GROUP BY category;
+----------+--------------+---------------+------------+
| category | STDDEV_POP(x) | STDDEV_SAMP(x) | VAR_POP(x) |
+----------+--------------+---------------+------------+
| a        |       0.8165 |        1.0000 |     0.6667 |
| b        |      18.0400 |       20.1693 |   325.4400 |
+----------+--------------+---------------+------------+
```

As a window function:

```
CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87);

SELECT name, test, score, VAR_SAMP(score)
  OVER (PARTITION BY test) AS variance_results FROM student_test;
+---------+--------+-------+------------------+
| name    | test   | score | variance_results |
+---------+--------+-------+------------------+
| Chun    | SQL    |    75 |         382.9167 |
| Chun    | Tuning |    73 |         873.0000 |
| Esben   | SQL    |    43 |         382.9167 |
| Esben   | Tuning |    31 |         873.0000 |
| Kaolin  | SQL    |    56 |         382.9167 |
| Kaolin  | Tuning |    88 |         873.0000 |
| Tatiana | SQL    |    87 |         382.9167 |
+---------+--------+-------+------------------+
```

See Also

- VAR_POP (variance)
- STDDEV_POP (population standard deviation)

This page is licensed: GPLv2, originally from fill_help_tables.sql

VARIANCE

Syntax

```
VARIANCE(expr)
```

Description

Returns the population standard variance of `expr`. This is an extension to standard SQL. The standard SQL function VAR_POP() can be used instead.

Variance is calculated by

- working out the mean for the set;
- for each number, subtracting the mean and squaring the result;
- calculating the average of the resulting differences.

It is an aggregate function, and so can be used with the GROUP BY clause.

`VARIANCE()` can be used as a window function.

`VARIANCE()` returns `NULL` if there were no matching rows.

Examples

```
CREATE TABLE v(i tinyint);

INSERT INTO v VALUES(101),(99);

SELECT VARIANCE(i) FROM v;
+-------------+
| VARIANCE(i) |
+-------------+
|      1.0000 |
+-------------+

INSERT INTO v VALUES(120),(80);

SELECT VARIANCE(i) FROM v;
+-------------+
| VARIANCE(i) |
+-------------+
|    200.5000 |
+-------------+
```

As an aggregate function:

```
CREATE OR REPLACE TABLE stats (category VARCHAR(2), x INT);

INSERT INTO stats VALUES
  ('a',1),('a',2),('a',3),
  ('b',11),('b',12),('b',20),('b',30),('b',60);

SELECT category, STDDEV_POP(x), STDDEV_SAMP(x), VAR_POP(x)
  FROM stats GROUP BY category;
+----------+---------------+----------------+------------+
| category | STDDEV_POP(x) | STDDEV_SAMP(x) | VAR_POP(x) |
+----------+---------------+----------------+------------+
| a        |        0.8165 |         1.0000 |     0.6667 |
| b        |       18.0400 |        20.1693 |   325.4400 |
+----------+---------------+----------------+------------+
```

As a window function:

```
CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87);

SELECT name, test, score, VAR_POP(score)
  OVER (PARTITION BY test) AS variance_results FROM student_test;
+---------+--------+-------+------------------+
| name    | test   | score | variance_results |
+---------+--------+-------+------------------+
| Chun    | SQL    |    75 |         287.1875 |
| Chun    | Tuning |    73 |         582.0000 |
| Esben   | SQL    |    43 |         287.1875 |
| Esben   | Tuning |    31 |         582.0000 |
| Kaolin  | SQL    |    56 |         287.1875 |
| Kaolin  | Tuning |    88 |         582.0000 |
| Tatiana | SQL    |    87 |         287.1875 |
+---------+--------+-------+------------------+
```

- VAR_POP (equivalent, standard SQL)
- STDDEV_POP (population standard deviation)
- STDDEV_SAMP (sample standard deviation)

This page is licensed: GPLv2, originally from fill_help_tables.sql

Control Flow Functions

See CASE OPERATOR.

Implement conditional logic in SQL queries. This operator evaluates conditions and returns a specific value when the first true condition is met.

See DECODE_ORACLE.

Compare a value against a list of conditions. This Oracle-compatible function returns a corresponding result when a match is found, or a default value otherwise.

See IF Function.

Complete IF() function reference: IF(expr1,expr2,expr3) conditional syntax, TRUE/NULL evaluation rules, return type context (numeric/string), and examples.

See IFNULL.

Replace NULL values with a fallback. This function returns the first argument if it's not NULL; otherwise, it returns the specified replacement value.

See NULLIF.

Compare two expressions and return NULL if they are equal. If the expressions differ, the function returns the first expression.

See NVL.

Synonym for IFNULL. This Oracle-compatible function returns the first argument if it is not NULL, or the second argument if the first is NULL.

See NVL2.

Return values based on NULL status. This function returns the second argument if the first is not NULL, and the third argument if the first is NULL.

This page is licensed: CC BY-SA / Gnu FDL

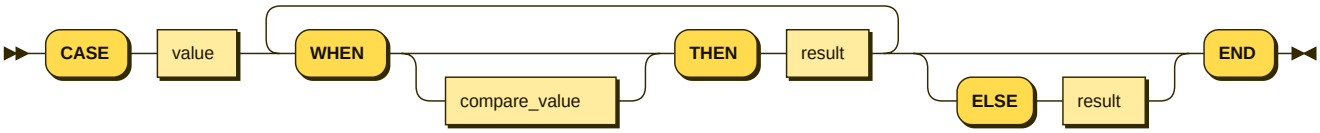
CASE OPERATOR

Syntax

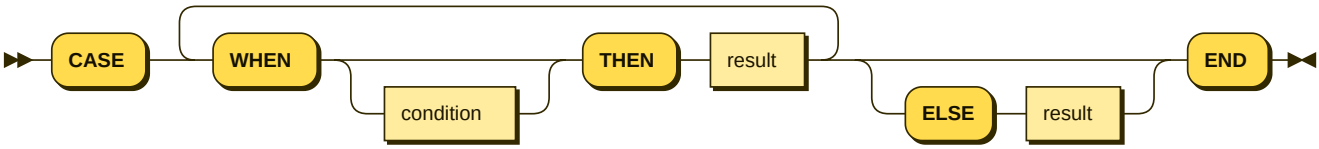
```
CASE value WHEN [compare_value] THEN result [WHEN [compare_value] THEN
result ...] [ELSE result] END

CASE WHEN [condition] THEN result [WHEN [condition] THEN result ...]
[ELSE result] END
```

The BNF documents the two CASE-operator forms (simple and searched); each gets its own diagram.



Railroad diagram of the simple CASE form



Railroad diagram of the searched CASE form

Description

The first version returns the result for the first `value=compare_value` comparison that is true. The second version returns the result for the first condition that is true. If there was no matching result value, the result after ELSE is returned, or NULL if there is no ELSE part.

There is also a CASE statement, which differs from the CASE operator described here.

Examples

```
SELECT CASE 1 WHEN 1 THEN 'one' WHEN 2 THEN 'two' ELSE 'more' END;
+-------------------------------------------------------------+
| CASE 1 WHEN 1 THEN 'one' WHEN 2 THEN 'two' ELSE 'more' END |
+-------------------------------------------------------------+
| one                                                         |
+-------------------------------------------------------------+

SELECT CASE WHEN 1>0 THEN 'true' ELSE 'false' END;
+----------------------------------------+
| CASE WHEN 1>0 THEN 'true' ELSE 'false' END |
+----------------------------------------+
| true                                   |
+----------------------------------------+

SELECT CASE BINARY 'B' WHEN 'a' THEN 1 WHEN 'b' THEN 2 END;
+-----------------------------------------------+
| CASE BINARY 'B' WHEN 'a' THEN 1 WHEN 'b' THEN 2 END |
+-----------------------------------------------+
|                                          NULL |
+-----------------------------------------------+
```

Only the first matching condition is processed:

```
SELECT
  CASE true
     WHEN (1=1) THEN '1=1' -- result is returned
     WHEN (1=1 OR 2=2) THEN '1=1 OR 2=2' -- condition not processed
     ELSE 'else'
  END
;
+-------------------------------------------------------------------------------------+
| CASE true WHEN (1=1) THEN '1=1' WHEN (1=1 OR 2=2) THEN '1=1 OR 2=2' ELSE 'else' END |
+-------------------------------------------------------------------------------------+
+ 1=1                                                                                 +
+-------------------------------------------------------------------------------------+
```

See Also

- The CASE statement, which differs from the CASE operator described above.
- The IF() function.
- Operator Precedence

This page is licensed: GPLv2, originally from fill_help_tables.sql

DECODE_ORACLE

`DECODE_ORACLE` is a synonym for the Oracle mode version of the DECODE function, and is available in all modes.

This page is licensed: CC BY-SA / Gnu FDL

IF Function

Syntax

```
IF(expr1,expr2,expr3)
```

Description

If `expr1` is `TRUE` (`expr1 <> 0` and `expr1 <> NULL`) then `IF()` returns `expr2`; otherwise it returns `expr3`. `IF()` returns a numeric or string value, depending on the context in which it is used.

Note: There is also an IF statement which differs from the `IF()` function described here.

Examples

```
SELECT IF(1>2,2,3);
+-------------+
| IF(1>2,2,3) |
+-------------+
|           3 |
+-------------+
```

```
SELECT IF(1<2,'yes','no');
+--------------------+
| IF(1<2,'yes','no') |
+--------------------+
| yes                |
+--------------------+
```

```
SELECT IF(STRCMP('test','test1'),'no','yes');
+---------------------------------------+
| IF(STRCMP('test','test1'),'no','yes') |
+---------------------------------------+
| no                                    |
+---------------------------------------+
```

See Also

There is also an IF statement, which differs from the `IF()` function described above.

This page is licensed: GPLv2, originally from fill_help_tables.sql

IFNULL

Syntax

```
IFNULL(expr1,expr2)
NVL(expr1,expr2)
```

Description

If *`expr1`* is not `NULL`, `IFNULL()` returns *`expr1`*; otherwise it returns_ `expr2` _. `IFNULL()` returns a numeric or string value, depending on the context in which it is used.

`NVL()` is an alias for `IFNULL()`.

Examples

```
SELECT IFNULL(1,0);
+-------------+
| IFNULL(1,0) |
+-------------+
|           1 |
+-------------+

SELECT IFNULL(NULL,10);
+-----------------+
| IFNULL(NULL,10) |
+-----------------+
|              10 |
+-----------------+

SELECT IFNULL(1/0,10);
+----------------+
| IFNULL(1/0,10) |
+----------------+
|        10.0000 |
+----------------+

SELECT IFNULL(1/0,'yes');
+-------------------+
| IFNULL(1/0,'yes') |
+-------------------+
| yes               |
+-------------------+
```

See Also

- NULL values
- IS NULL operator
- IS NOT NULL operator

- COALESCE function
- NULLIF function
- CONNECT data types

This page is licensed: GPLv2, originally from fill_help_tables.sql

NULLIF

Syntax

```
NULLIF(expr1,expr2)
```

Description

Returns `NULL` if expr1 = expr2 is true, otherwise returns expr1. This is the same as CASE `WHEN` expr1 = expr2 `THEN NULL ELSE` expr1 `END`.

Examples

```
SELECT NULLIF(1,1);
+-------------+
| NULLIF(1,1) |
+-------------+
|        NULL |
+-------------+

SELECT NULLIF(1,2);
+-------------+
| NULLIF(1,2) |
+-------------+
|           1 |
+-------------+
```

See Also

- NULL values
- IS NULL operator
- IS NOT NULL operator
- COALESCE function
- IFNULL function
- CONNECT data types

This page is licensed: GPLv2, originally from fill_help_tables.sql

NVL

`NVL` is a synonym for IFNULL.

This page is licensed: CC BY-SA / Gnu FDL

NVL2

Syntax

```
NVL2(expr1,expr2,expr3)
```

Description

The `NVL2` function returns a value based on whether a specified expression is `NULL` or not. If *expr1* is not `NULL`, then `NVL2` returns *expr2*. If *expr1* is `NULL`, then `NVL2` returns *expr3*.

Examples

```
SELECT NVL2(NULL,1,2);
+----------------+
| NVL2(NULL,1,2) |
+----------------+
|              2 |
+----------------+

SELECT NVL2('x',1,2);
+---------------+
| NVL2('x',1,2) |
+---------------+
|             1 |
+---------------+
```

Date & Time Functions

See Date and Time Units.

Reference keywords for date arithmetic. These units, such as DAY, HOUR, and MINUTE, specify the interval type used in functions like DATE_ADD and EXTRACT.

See ADD_MONTHS.

Add a specific number of months to a date. This Oracle-compatible function simplifies date calculations involving monthly intervals.

See ADDDATE.

Add a time interval to a date. This function performs date arithmetic, adding a specified value like days or hours to a starting date.

See ADDTIME.

Add a time value to a date or time expression. This function sums two time arguments, returning a new time or datetime result.

See CONVERT_TZ.

Convert a datetime value between time zones. This function shifts a timestamp from a source time zone to a target time zone.

See CURDATE.

Return the current date. This function outputs today's date as a value in 'YYYY-MM-DD' or YYYYMMDD format, depending on the context.

See CURRENT_DATE.

Synonym for CURDATE(). Returns the current date as a value in 'YYYY-MM-DD' or YYYYMMDD format.

See CURRENT_TIME.

Synonym for CURTIME(). Returns the current time as a value in ‘HH:MM:SS’ or HHMMSS format.

See CURRENT_TIMESTAMP.

Synonym for NOW(). Returns the current date and time as a value in ‘YYYY-MM-DD HH:MM:SS’ or YYYYMMDDHHMMSS format.

See CURTIME.

Return the current time. This function outputs the current time of day as a value in ‘HH:MM:SS’ or HHMMSS format.

See DATE FUNCTION.

Extract the date part from a datetime expression. This function returns the year, month, and day portions, discarding the time component.

See DATE_ADD.

Complete DATE_ADD() reference: DATE_ADD(date, INTERVAL expr unit) syntax, negative interval support, unit keywords (DAY/MONTH/YEAR), and return types.

See DATE_FORMAT.

Complete DATE_FORMAT reference for MariaDB. Complete function guide with syntax, parameters, return values, and usage examples with comprehensive examples.

See DATE_SUB.

Subtract a time interval from a date. This function calculates a past date by subtracting a specified unit, such as days, from a starting value.

See DATEDIFF.

Complete DATEDIFF() reference: DATEDIFF(expr1,expr2) syntax, date vs datetime expression handling, time component ignore, and positive/negative results.

See DAY.

Synonym for DAYOFMONTH(). Returns the day of the month (1-31) for a given date.

See DAYNAME.

Return the name of the weekday. This function returns the full name of the day, such as ‘Monday’ or ‘Sunday’, for a given date.

See DAYOFMONTH.

Return the day of the month. This function extracts the day portion of a date, returning a number from 1 to 31.

See DAYOFWEEK.

Return the weekday index. This function returns a number from 1 (Sunday) to 7 (Saturday) representing the day of the week.

See DAYOFYEAR.

Return the day of the year. This function returns a number from 1 to 366 indicating the day’s position within the year.

See EXTRACT.

Extract a specific part of a date. This function retrieves components like YEAR, MONTH, DAY, or HOUR from a date or datetime expression.

See FORMAT_PICO_TIME.

Format a time in picoseconds. This function converts a numeric picosecond value into a human-readable string with units like ps, ns, us, ms, s, m, h, or d.

See FROM_DAYS.

Convert a day number to a date. This function returns a DATE value corresponding to the number of days since year 0.

See FROM_UNIXTIME.

Convert a Unix timestamp to a datetime. This function formats a Unix timestamp as a date string or number in the current time zone.

See GET_FORMAT.

Return a format string. This function provides standard format strings for DATE_FORMAT and STR_TO_DATE based on regions like 'USA' or 'EUR'.

See HOUR.

Extract the hour. This function returns the hour portion of a time or datetime value as a number from 0 to 23.

See LAST_DAY.

Return the last day of the month. This function calculates the date of the final day for the month containing the given date.

See LOCALTIME.

Synonym for NOW(). Returns the current date and time in the session time zone.

See LOCALTIMESTAMP.

Synonym for NOW(). Returns the current date and time in the session time zone as a datetime value.

See MAKEDATE.

Create a date from a year and day of year. This function constructs a DATE value given a year and the day number within that year.

See MAKETIME.

Create a time from hour, minute, and second. This function constructs a TIME value from three numeric arguments.

See MICROSECOND.

Extract microseconds. This function returns the microsecond part of a time or datetime expression as a number from 0 to 999999.

See Microseconds in MariaDB.

Understand microsecond precision. This concept page explains how MariaDB stores and handles fractional seconds in time data types.

See MINUTE.

Extract the minute. This function returns the minute portion of a time or datetime value as a number from 0 to 59.

See MONTH.

Extract the month. This function returns the month portion of a date as a number from 1 (January) to 12 (December).

See MONTHNAME.

Return the name of the month. This function returns the full name of the month, such as ‘January’ or ‘December’, for a given date.

See MONTHS_BETWEEN.

Calculate the difference between two months.

See NOW.

Complete NOW() function reference: NOW(precision) and CURRENT_TIMESTAMP synonyms, TIMESTAMP vs DATETIME types, timezone/DST handling, and fractional seconds.

See PERIOD_ADD.

Add months to a period. This function adds a specified number of months to a period formatted as YYMM or YYYYMM.

See PERIOD_DIFF.

Calculate the difference between periods. This function returns the number of months between two periods formatted as YYMM or YYYYMM.

See QUARTER.

Return the quarter of the year. This function returns a number from 1 to 4 indicating the quarter for a given date.

See SEC_TO_TIME.

Convert seconds to time. This function returns a TIME value corresponding to the number of seconds elapsed from the start of the day.

See SECOND.

Extract the second. This function returns the second portion of a time or datetime value as a number from 0 to 59.

See STR_TO_DATE.

Complete STR_TO_DATE() reference: parse strings to DATE/TIME/DATETIME, format specifiers (%Y %m %d %H %i %s), invalid input handling, and SQL_MODE errors.

See SUBDATE.

Subtract a time interval from a date. This synonym for DATE_SUB calculates a past date by subtracting a specified unit from a starting value.

See SUBTIME.

Subtract a time value. This function subtracts one time or datetime expression from another and returns the result.

See SYSDATE.

Return the time of execution. Unlike NOW(), which returns the start time of the statement, SYSDATE() returns the time it executes.

See TIME.

Extract the time portion. This function returns the time part of a time or datetime expression.

See TIME_FORMAT.

Format a time. This function formats a time value according to a format string, similar to DATE_FORMAT but for time values.

See TIME_TO_SEC.

TIME_TO_SEC() converts a time value to the number of seconds, returning a DOUBLE that preserves microseconds.

See TIMEDIFF.

Subtract two time values. This function calculates the difference between two time or datetime expressions.

See TIMESTAMP.

Convert to datetime or add time. With one argument, it returns a datetime; with two, it adds a time expression to a date or datetime.

See TIMESTAMPADD.

Add an interval to a timestamp. This function adds a specified integer number of units (like MONTH or SECOND) to a datetime expression.

See TIMESTAMPDIFF.

Calculate the difference between timestamps. This function returns the difference between two datetime expressions in the specified unit.

See TO_DATE.

TO_DATE() converts a string to a date using a specified format, with optional handling for conversion errors.

See TO_DAYS.

Convert a date to a day number. This function returns the number of days between year 0 and the given date.

See TO_SECONDS.

Convert a date to seconds. This function returns the number of seconds from year 0 to the given date or datetime.

See TRUNC.

Truncate a date. In Oracle mode, this function truncates a date value to a specified unit of measure.

See UNIX_TIMESTAMP.

Return a Unix timestamp. This function returns the number of seconds since the Unix Epoch (‘1970-01-01 00:00:00’ UTC).

See UTC_DATE.

Return the current UTC date. This function returns the current Coordinated Universal Time date in ‘YYYY-MM-DD’ or YYYYMMDD format.

See UTC_TIME.

Return the current UTC time. This function returns the current Coordinated Universal Time in ‘HH:MM:SS’ or HHMMSS format.

See UTC_TIMESTAMP.

Return the current UTC timestamp. This function returns the current Coordinated Universal Time date and time.

See WEEK.

Return the week number. This function returns the week number for a date, with an optional mode to define the start of the week.

See WEEKDAY.

Return the weekday index. This function returns the index of the day of the week (0=Monday, 6=Sunday).

See WEEKOFYEAR.

Return the calendar week. This function returns the week number of the date (1-53), equivalent to WEEK(date, 3).

See YEAR.

Extract the year. This function returns the year portion of a date as a number from 1000 to 9999.

See YEARWEEK.

Return the year and week. This function returns the year and week number for a date, useful for grouping results by week.

Date and Time Units

The `INTERVAL` keyword can be used to add or subtract a time interval of time to a DATETIME, DATE or TIME value.

The syntax is:

```
INTERVAL time_quantity time_unit
```

For example, the `SECOND` unit is used below by the DATE_ADD() function:

```
SELECT '2008-12-31 23:59:59' + INTERVAL 1 SECOND;
+----------------------------------------+
| '2008-12-31 23:59:59' + INTERVAL 1 SECOND |
+----------------------------------------+
| 2009-01-01 00:00:00                    |
+----------------------------------------+
```

The following units are valid:

Unit	Description
MICROSECOND	Microseconds
SECOND	Seconds
MINUTE	Minutes
HOUR	Hours
DAY	Days
WEEK	Weeks
MONTH	Months
QUARTER	Quarters
YEAR	Years
SECOND_MICROSECOND	Seconds.Microseconds
MINUTE_MICROSECOND	Minutes.Seconds.Microseconds
MINUTE_SECOND	Minutes.Seconds
HOUR_MICROSECOND	Hours.Minutes.Seconds.Microseconds
HOUR_SECOND	Hours.Minutes.Seconds
HOUR_MINUTE	Hours.Minutes
DAY_MICROSECOND	Days Hours.Minutes.Seconds.Microseconds
DAY_SECOND	Days Hours.Minutes.Seconds
DAY_MINUTE	Days Hours.Minutes

Unit	Description
DAY_HOUR	Days Hours
YEAR_MONTH	Years-Months

The time units containing an underscore are composite; that is, they consist of multiple base time units. For base time units, `time_quantity` is an integer number. For composite units, the quantity must be expressed as a string with multiple integer numbers separated by any punctuation character.

Example of composite units:

```
INTERVAL '2:2' YEAR_MONTH
INTERVAL '1:30:30' HOUR_SECOND
INTERVAL '1!30!30' HOUR_SECOND -- same as above
```

Time units can be used in the following contexts:

- after a + or a - operator;
- with the following `DATE` or `TIME` functions: ADDDATE(), SUBDATE(), DATE_ADD(), DATE_SUB(), TIMESTAMPADD(), TIMESTAMPDIFF(), EXTRACT();
- in the `ON SCHEDULE` clause of CREATE EVENT and ALTER EVENT;
- when defining a partitioning `BY SYSTEM_TIME` .

ADD_MONTHS

> **Note:**
>
> `ADD_MONTHS` is available from MariaDB 10.6.1.

The `ADD_MONTHS` function was introduced to enhance Oracle compatibility. Similar functionality can be achieved with the DATE_ADD function.

Syntax

```
ADD_MONTHS(date, months)
```

Description

`ADD_MONTHS` adds an integer *months* to a given *date* (DATE, DATETIME or TIMESTAMP), returning the resulting date.

`months` can be positive or negative. If months is not a whole number, it is rounded to the nearest whole number (not truncated).

The resulting day component will remain the same as that specified in *date*, unless the resulting month has fewer days than the day component of the given date, in which case the day will be the last day of the resulting month.

Returns `NULL` if given an invalid date or a `NULL` argument.

Examples

```
SELECT ADD_MONTHS('2012-01-31', 2);
+----------------------------+
| ADD_MONTHS('2012-01-31', 2) |
+----------------------------+
| 2012-03-31                 |
+----------------------------+

SELECT ADD_MONTHS('2012-01-31', -5);
+-----------------------------+
| ADD_MONTHS('2012-01-31', -5) |
+-----------------------------+
| 2011-08-31                  |
+-----------------------------+

SELECT ADD_MONTHS('2011-01-31', 1);
+----------------------------+
| ADD_MONTHS('2011-01-31', 1) |
+----------------------------+
| 2011-02-28                 |
+----------------------------+

SELECT ADD_MONTHS('2012-01-31', 1);
+----------------------------+
| ADD_MONTHS('2012-01-31', 1) |
+----------------------------+
| 2012-02-29                 |
+----------------------------+

SELECT ADD_MONTHS('2012-01-31', 2);
+----------------------------+
| ADD_MONTHS('2012-01-31', 2) |
+----------------------------+
| 2012-03-31                 |
+----------------------------+

SELECT ADD_MONTHS('2012-01-31', 3);
+----------------------------+
| ADD_MONTHS('2012-01-31', 3) |
+----------------------------+
| 2012-04-30                 |
+----------------------------+

SELECT ADD_MONTHS('2011-01-15', 2.5);
+-----------------------------+
| ADD_MONTHS('2011-01-15', 2.5) |
+-----------------------------+
| 2011-04-15                  |
+-----------------------------+
1 row in set (0.001 sec)

SELECT ADD_MONTHS('2011-01-15', 2.6);
+-----------------------------+
| ADD_MONTHS('2011-01-15', 2.6) |
+-----------------------------+
| 2011-04-15                  |
+-----------------------------+
1 row in set (0.001 sec)

SELECT ADD_MONTHS('2011-01-15', 2.1);
+-----------------------------+
| ADD_MONTHS('2011-01-15', 2.1) |
+-----------------------------+
| 2011-03-15                  |
+-----------------------------+
1 row in set (0.004 sec)
```

ADDDATE

Syntax

```
ADDDATE(date,INTERVAL expr unit), ADDDATE(expr,days)
```

Description

When invoked with the `INTERVAL` form of the second argument, `ADDDATE()` is a synonym for DATE_ADD(). The related function SUBDATE() is a synonym for DATE_SUB(). For information on the `INTERVAL` unit argument, see the discussion for DATE_ADD().

When invoked with the days form of the second argument, MariaDB treats it as an integer number of days to be added to *expr*.

Examples

```
SELECT DATE_ADD('2008-01-02', INTERVAL 31 DAY);
+----------------------------------------+
| DATE_ADD('2008-01-02', INTERVAL 31 DAY) |
+----------------------------------------+
| 2008-02-02                             |
+----------------------------------------+

SELECT ADDDATE('2008-01-02', INTERVAL 31 DAY);
+----------------------------------------+
| ADDDATE('2008-01-02', INTERVAL 31 DAY) |
+----------------------------------------+
| 2008-02-02                             |
+----------------------------------------+
```

```
SELECT ADDDATE('2008-01-02', 31);
+---------------------------+
| ADDDATE('2008-01-02', 31) |
+---------------------------+
| 2008-02-02                |
+---------------------------+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
SELECT d, ADDDATE(d, 10) from t1;
+---------------------+---------------------+
| d                   | ADDDATE(d, 10)      |
+---------------------+---------------------+
| 2007-01-30 21:31:07 | 2007-02-09 21:31:07 |
| 1983-10-15 06:42:51 | 1983-10-25 06:42:51 |
| 2011-04-21 12:34:56 | 2011-05-01 12:34:56 |
| 2011-10-30 06:31:41 | 2011-11-09 06:31:41 |
| 2011-01-30 14:03:25 | 2011-02-09 14:03:25 |
| 2004-10-07 11:19:34 | 2004-10-17 11:19:34 |
+---------------------+---------------------+

SELECT d, ADDDATE(d, INTERVAL 10 HOUR) from t1;
+---------------------+-----------------------------+
| d                   | ADDDATE(d, INTERVAL 10 HOUR) |
+---------------------+-----------------------------+
| 2007-01-30 21:31:07 | 2007-01-31 07:31:07          |
| 1983-10-15 06:42:51 | 1983-10-15 16:42:51          |
| 2011-04-21 12:34:56 | 2011-04-21 22:34:56          |
| 2011-10-30 06:31:41 | 2011-10-30 16:31:41          |
| 2011-01-30 14:03:25 | 2011-01-31 00:03:25          |
| 2004-10-07 11:19:34 | 2004-10-07 21:19:34          |
+---------------------+-----------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ADDTIME

Syntax

```
ADDTIME(expr1,expr2)
```

Description

`ADDTIME()` adds *expr2* to *expr1* and returns the result. *expr1* is a time or datetime expression, and *expr2* is a time expression.

Examples

```
SELECT ADDTIME('2007-12-31 23:59:59.999999', '1 1:1:1.000002');
+----------------------------------------------------------+
| ADDTIME('2007-12-31 23:59:59.999999', '1 1:1:1.000002') |
+----------------------------------------------------------+
| 2008-01-02 01:01:01.000001                               |
+----------------------------------------------------------+

SELECT ADDTIME('01:00:00.999999', '02:00:00.999998');
+---------------------------------------------+
| ADDTIME('01:00:00.999999', '02:00:00.999998') |
+---------------------------------------------+
| 03:00:01.999997                             |
+---------------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

CONVERT_TZ

Syntax

```
CONVERT_TZ(dt,from_tz,to_tz)
```

Description

`CONVERT_TZ()` converts a datetime value *dt* from the time zone given by *from_tz* to the time zone given by *to_tz* and returns the resulting value.

In order to use named time zones, such as GMT, MET or Africa/Johannesburg, the `time_zone` tables must be loaded (see mysql_tzinfo_to_sql).

No conversion takes place if the value falls outside of the supported `TIMESTAMP` range when converted from *from_tz* to UTC.

> **CURRENT**
>
> The supported range is `1970-01-01 00:00:00` to `2106-02-07 06:28:15` UTC.
>
> **< 11.5**
>
> The supported range is `1970-01-01 00:00:01` to `2038-01-19 05:14:07` UTC.

This function returns `NULL` if the arguments are invalid (or named time zones have not been loaded).

See time zones for more information.

Examples

```
SELECT CONVERT_TZ('2016-01-01 12:00:00','+00:00','+10:00');
+---------------------------------------------------+
| CONVERT_TZ('2016-01-01 12:00:00','+00:00','+10:00') |
+---------------------------------------------------+
| 2016-01-01 22:00:00                               |
+---------------------------------------------------+
```

Using named time zones (with the time zone tables loaded):

```
SELECT CONVERT_TZ('2016-01-01 12:00:00','GMT','Africa/Johannesburg');
+-------------------------------------------------------------+
| CONVERT_TZ('2016-01-01 12:00:00','GMT','Africa/Johannesburg') |
+-------------------------------------------------------------+
| 2016-01-01 14:00:00                                         |
+-------------------------------------------------------------+
```

The value is out of the `TIMESTAMP` range, so no conversion takes place:

```
SELECT CONVERT_TZ('1969-12-31 22:00:00','+00:00','+10:00');
+---------------------------------------------------+
| CONVERT_TZ('1969-12-31 22:00:00','+00:00','+10:00') |
+---------------------------------------------------+
| 1969-12-31 22:00:00                               |
+---------------------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

CURDATE

Syntax

```
CURDATE()
CURRENT_DATE
CURRENT_DATE()
```

Description

`CURDATE` returns the current date as a value in `YYYY-MM-DD` or `YYYYMMDD` format, depending on whether the function is used in a string or numeric context.

`CURRENT_DATE` and `CURRENT_DATE()` are synonyms.

Examples

```
SELECT CURDATE();
+------------+
| CURDATE()  |
+------------+
| 2019-03-05 |
+------------+
```

In a numeric context (note this is not performing date calculations):

```
SELECT CURDATE() +0;
+--------------+
| CURDATE() +0 |
+--------------+
|     20190305 |
+--------------+
```

Date calculation:

```
SELECT CURDATE() - INTERVAL 5 DAY;
+----------------------------+
| CURDATE() - INTERVAL 5 DAY |
+----------------------------+
| 2019-02-28                 |
+----------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

CURRENT_DATE

Syntax

```
CURRENT_DATE, CURRENT_DATE()
```

Description

`CURRENT_DATE` and `CURRENT_DATE()` are synonyms for CURDATE().

This page is licensed: GPLv2, originally from fill_help_tables.sql

CURRENT_TIME

Syntax

```
CURRENT_TIME
CURRENT_TIME([precision])
```

Description

`CURRENT_TIME` and `CURRENT_TIME()` are synonyms for CURTIME().

See Also

- Microseconds in MariaDB

This page is licensed: GPLv2, originally from fill_help_tables.sql

CURRENT_TIMESTAMP

Syntax

```
CURRENT_TIMESTAMP
CURRENT_TIMESTAMP([precision])
```

Description

`CURRENT_TIMESTAMP` and `CURRENT_TIMESTAMP()` are synonyms for NOW().

See Also

- Microseconds in MariaDB
- The TIMESTAMP data type

This page is licensed: GPLv2, originally from fill_help_tables.sql

CURTIME

Syntax

```
CURTIME([precision])
```

Description

Returns the current time as a value in `HH:MM:SS` or `HHMMSS.uuuuuu` format, depending on whether the function is used in a string or numeric context. The value is expressed in the current time zone.

The optional *precision* determines the microsecond precision. See Microseconds in MariaDB.

Examples

```
SELECT CURTIME();
+-----------+
| CURTIME() |
+-----------+
| 12:45:39  |
+-----------+

SELECT CURTIME() + 0;
+---------------+
| CURTIME() + 0 |
+---------------+
| 124545.000000 |
+---------------+
```

With precision:

```
SELECT CURTIME(2);
+-------------+
| CURTIME(2)  |
+-------------+
| 09:49:08.09 |
+-------------+
```

See Also

- Microseconds in MariaDB

This page is licensed: GPLv2, originally from fill_help_tables.sql

DATE FUNCTION

Syntax

```
DATE(expr)
```

Description

Extracts the date part of the date or datetime expression *expr*. Returns NULL and throws a warning when passed an invalid date.

Examples

```
SELECT DATE('2013-07-18 12:21:32');
+----------------------------+
| DATE('2013-07-18 12:21:32') |
+----------------------------+
| 2013-07-18                 |
+----------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

DATE_ADD

Syntax

```
DATE_ADD(date,INTERVAL expr unit)
```

Description

Performs date arithmetic. The *date* argument specifies the starting date or datetime value. *expr* is an expression specifying the interval value to be added to the starting date. *expr* is a string; it may start with a "`-`" for negative intervals. For composite interval units (such as DAY_HOUR, MINUTE_SECOND, and SECOND_MICROSECOND), *expr* can contain multiple components separated by spaces or punctuation. For example:

- '1 10' DAY_HOUR represents 1 day and 10 hours
- '1:1' MINUTE_SECOND represents 1 minute and 1 second
- '1.999999' SECOND_MICROSECOND represents seconds and microseconds

The exact format of *expr* depends on the *unit* specified.

unit is a keyword indicating the units in which the expression should be interpreted. See Date and Time Units for a complete list of permitted units.

The result type of `DATE_ADD()` is determined as follows:

- if the first argument is of the type `DATETIME`, the function returns `DATETIME`;
- if the first argument is `DATE` and the interval uses `HOUR` or smaller units, the function returns `DATETIME`;
- if the first argument is `DATE` and the interval uses `DAY` or larger units, the function returns `DATE`;
- similarly, if the first argument is `TIME` and the interval uses `DAY` or smaller units the function returns `TIME`, if the interval uses anything larger, the function returns `DATETIME`;

- if the first argument isn't a temporal type, the function returns a string.

Examples

```
SELECT '2008-12-31 23:59:59' + INTERVAL 1 SECOND;
+-----------------------------------------+
| '2008-12-31 23:59:59' + INTERVAL 1 SECOND |
+-----------------------------------------+
| 2009-01-01 00:00:00                     |
+-----------------------------------------+
```

```
SELECT INTERVAL 1 DAY + '2008-12-31';
+-------------------------------+
| INTERVAL 1 DAY + '2008-12-31' |
+-------------------------------+
| 2009-01-01                    |
+-------------------------------+
```

```
SELECT '2005-01-01' - INTERVAL 1 SECOND;
+---------------------------------+
| '2005-01-01' - INTERVAL 1 SECOND |
+---------------------------------+
| 2004-12-31 23:59:59             |
+---------------------------------+
```

```
SELECT DATE_ADD('2000-12-31 23:59:59', INTERVAL 1 SECOND);
+-------------------------------------------------+
| DATE_ADD('2000-12-31 23:59:59', INTERVAL 1 SECOND) |
+-------------------------------------------------+
| 2001-01-01 00:00:00                             |
+-------------------------------------------------+
```

```
SELECT DATE_ADD('2010-12-31 23:59:59', INTERVAL 1 DAY);
+----------------------------------------------+
| DATE_ADD('2010-12-31 23:59:59', INTERVAL 1 DAY) |
+----------------------------------------------+
| 2011-01-01 23:59:59                          |
+----------------------------------------------+
```

```
SELECT DATE_ADD('2100-12-31 23:59:59', INTERVAL '1:1' MINUTE_SECOND);
+---------------------------------------------------------------+
| DATE_ADD('2100-12-31 23:59:59', INTERVAL '1:1' MINUTE_SECOND) |
+---------------------------------------------------------------+

DATE_FORMAT

Syntax

```
DATE_FORMAT(date, format[, locale])
```

Description

Formats the date value according to the format string.

The language used for the names is controlled by the value of the lc_time_names system variable. See server locale for more on the supported locales.

Date Formatting Options

The options that can be used by `DATE_FORMAT()`, as well as its inverse STR_TO_DATE() and the FROM_UNIXTIME() function, are:

Option	Description
%a	Short weekday name in current locale (Variable lc_time_names).
%b	Short form month name in current locale. For locale `en_US` this is one of: Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, or Dec.
%c	Month with 1 or 2 digits.
%D	Day with English suffix ‘th’, ‘nd’, ‘st’ or ‘rd’’. (1st, 2nd, 3rd…).
%d	Day with 2 digits.
%e	Day with 1 or 2 digits.
%f	Microseconds 6 digits.
%H	Hour with 2 digits between 00-23.
%h	Hour with 2 digits between 01-12.
%I	Hour with 2 digits between 01-12.
%i	Minute with 2 digits.
%j	Day of the year (001-366)
%k	Hour with 1 digits between 0-23.
%l	Hour with 1 digits between 1-12.
%M	Full month name in current locale (Variable lc_time_names).
%m	Month with 2 digits.
%p	AM/PM according to current locale (Variable lc_time_names).
%r	Time in 12 hour format, followed by AM/PM. Short for ‘%I:%i:%S %p’.
%S	Seconds with 2 digits.
%s	Seconds with 2 digits.
%T	Time in 24 hour format. Short for ‘%H:%i:%S’.

Option	Description
%U	Week number (00-53), when first day of the week is Sunday.
%u	Week number (00-53), when first day of the week is Monday.
%V	Week number (01-53), when first day of the week is Sunday. Used with %X.
%v	Week number (01-53), when first day of the week is Monday. Used with %x.
%W	Full weekday name in current locale (Variable lc_time_names).
%w	Day of the week. 0 = Sunday, 6 = Saturday.
%X	Year with 4 digits when first day of the week is Sunday. Used with %V.
%x	Year with 4 digits when first day of the week is Monday. Used with %v.
%Y	Year with 4 digits.
%y	Year with 2 digits.
%Z	Timezone abbreviation. From MariaDB 11.3.0.
%z	Numeric timezone +hhmm or -hhmm presenting the hour and minute offset from UTC. From MariaDB 11.3.0.
%#	For str_to_date(), skip all numbers.
%.	For str_to_date(), skip all punctuation characters.
%@	For str_to_date(), skip all alpha characters.
%%	A literal % character.

To get a date in one of the standard formats, GET_FORMAT() can be used.

Examples

```
SELECT DATE_FORMAT('2009-10-04 22:23:00', '%W %M %Y');
+-----------------------------------------------+
| DATE_FORMAT('2009-10-04 22:23:00', '%W %M %Y') |
+-----------------------------------------------+
| Sunday October 2009                           |
+-----------------------------------------------+

SELECT DATE_FORMAT('2007-10-04 22:23:00', '%H:%i:%s');
+-----------------------------------------------+
| DATE_FORMAT('2007-10-04 22:23:00', '%H:%i:%s') |
+-----------------------------------------------+
| 22:23:00                                      |
+-----------------------------------------------+

SELECT DATE_FORMAT('1900-10-04 22:23:00', '%D %y %a %d %m %b %j');
+------------------------------------------------------------+
| DATE_FORMAT('1900-10-04 22:23:00', '%D %y %a %d %m %b %j') |
+------------------------------------------------------------+
| 4th 00 Thu 04 10 Oct 277                                   |
+------------------------------------------------------------+

SELECT DATE_FORMAT('1997-10-04 22:23:00', '%H %k %I %r %T %S %w');
+------------------------------------------------------------+
| DATE_FORMAT('1997-10-04 22:23:00', '%H %k %I %r %T %S %w') |
+------------------------------------------------------------+
| 22 22 10 10:23:00 PM 22:23:00 00 6                         |
+------------------------------------------------------------+

SELECT DATE_FORMAT('1999-01-01', '%X %V');
+-----------------------------------+
| DATE_FORMAT('1999-01-01', '%X %V') |
+-----------------------------------+
| 1998 52                           |
+-----------------------------------+

SELECT DATE_FORMAT('2006-06-00', '%d');
+---------------------------------+
| DATE_FORMAT('2006-06-00', '%d') |
+---------------------------------+
| 00                              |
+---------------------------------+
```

Optionally, the locale can be explicitly specified as the third `DATE_FORMAT()` argument. Doing so makes the function independent from the session settings, and the three argument version of `DATE_FORMAT()` can be used in virtual indexed and persistent generated-columns:

```
SELECT DATE_FORMAT('2006-01-01', '%W', 'el_GR');
+-----------------------------------------+
| DATE_FORMAT('2006-01-01', '%W', 'el_GR') |
+-----------------------------------------+
| Κυριακή                                 |
+-----------------------------------------+
```

Format the current date and time in German date-time format:

```
SELECT DATE_FORMAT(NOW(),'%W, %e. %M %Y, %k:%i Uhr (%Z)','de_DE');
+------------------------------------------------------------+
| DATE_FORMAT(NOW(),'%W, %e. %M %Y, %k:%i Uhr (%Z)','de_DE') |
+------------------------------------------------------------+
| Donnerstag, 5. February 2026, 20:50 Uhr (CET)              |
+------------------------------------------------------------+
```

> **Note:**
>
> Timezone information from MariaDB 11.3:

```
SELECT DATE_FORMAT(NOW(), '%W %d %M %Y %H:%i:%s %Z %z');
+-------------------------------------------------+
| DATE_FORMAT(NOW(), '%W %d %M %Y %H:%i:%s %Z %z') |
+-------------------------------------------------+
| Wednesday 20 September 2023 15:00:23 SAST +0200  |
+-------------------------------------------------+
```

- STR_TO_DATE()
- FROM_UNIXTIME()

This page is licensed: GPLv2, originally from fill_help_tables.sql

DATE_SUB

Syntax

```
DATE_SUB(date,INTERVAL expr unit)
```

Description

Performs date arithmetic. The *date* argument specifies the starting date or datetime value. *expr* is an expression specifying the interval value to be subtracted from the starting date. *expr* is a string; it may start with a "`-`" for negative intervals. *unit* is a keyword indicating the units in which the expression should be interpreted. See Date and Time Units for a complete list of permitted units.

See also DATE_ADD().

Examples

```
SELECT DATE_SUB('1998-01-02', INTERVAL 31 DAY);
+----------------------------------------+
| DATE_SUB('1998-01-02', INTERVAL 31 DAY) |
+----------------------------------------+
| 1997-12-02                             |
+----------------------------------------+
```

```
SELECT DATE_SUB('2005-01-01 00:00:00', INTERVAL '1 1:1:1' DAY_SECOND);
+-----------------------------------------------------------------+
| DATE_SUB('2005-01-01 00:00:00', INTERVAL '1 1:1:1' DAY_SECOND) |
+-----------------------------------------------------------------+
| 2004-12-30 22:58:59                                             |
+-----------------------------------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

DATEDIFF

Syntax

```
DATEDIFF(expr1,expr2)
```

Description

`DATEDIFF()` returns (*expr1* – *expr2*) expressed as a value in days from one date to the other. *expr1* and *expr2* are date or date-and-time expressions. Only the date parts of the values are used in the calculation.

Examples

```
SELECT DATEDIFF('2007-12-31 23:59:59','2007-12-30');
+----------------------------------------------+
| DATEDIFF('2007-12-31 23:59:59','2007-12-30') |
+----------------------------------------------+
|                                            1 |
+----------------------------------------------+

SELECT DATEDIFF('2010-11-30 23:59:59','2010-12-31');
+----------------------------------------------+
| DATEDIFF('2010-11-30 23:59:59','2010-12-31') |
+----------------------------------------------+
|                                          -31 |
+----------------------------------------------+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
SELECT NOW();
+---------------------+
| NOW()               |
+---------------------+
| 2011-05-23 10:56:05 |
+---------------------+

SELECT d, DATEDIFF(NOW(),d) FROM t1;
+---------------------+-------------------+
| d                   | DATEDIFF(NOW(),d) |
+---------------------+-------------------+
| 2007-01-30 21:31:07 |              1574 |
| 1983-10-15 06:42:51 |             10082 |
| 2011-04-21 12:34:56 |                32 |
| 2011-10-30 06:31:41 |              -160 |
| 2011-01-30 14:03:25 |               113 |
| 2004-10-07 11:19:34 |              2419 |
+---------------------+-------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

DAY

Syntax

```
DAY(date)
```

Description

`DAY()` is a synonym for DAYOFMONTH().

This page is licensed: GPLv2, originally from fill_help_tables.sql

DAYNAME

Syntax

```
DAYNAME(date)
```

Description

Returns the name of the weekday for date. The language used for the name is controlled by the value of the lc_time_names system variable. See server locale for more on the supported locales.

Examples

```
SELECT DAYNAME('2007-02-03');
+----------------------+
| DAYNAME('2007-02-03') |
+----------------------+
| Saturday              |
+----------------------+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
SELECT d, DAYNAME(d) FROM t1;
+---------------------+------------+
| d                   | DAYNAME(d) |
+---------------------+------------+
| 2007-01-30 21:31:07 | Tuesday    |
| 1983-10-15 06:42:51 | Saturday   |
| 2011-04-21 12:34:56 | Thursday   |
| 2011-10-30 06:31:41 | Sunday     |
| 2011-01-30 14:03:25 | Sunday     |
| 2004-10-07 11:19:34 | Thursday   |
+---------------------+------------+
```

Changing the locale:

```
SET lc_time_names = 'fr_CA';

SELECT DAYNAME('2013-04-01');
+----------------------+
| DAYNAME('2013-04-01') |
+----------------------+
| lundi                 |
+----------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

DAYOFMONTH

Syntax

```
DAYOFMONTH(date)
```

Description

Returns the day of the month for date, in the range `1` to `31`, or `0` for dates such as `'0000-00-00'` or `'2008-00-00'` which have a zero day part.

`DAY()` is a synonym.

Examples

```
SELECT DAYOFMONTH('2007-02-03');
+--------------------------+
| DAYOFMONTH('2007-02-03') |
+--------------------------+
|                        3 |
+--------------------------+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
SELECT d FROM t1 where DAYOFMONTH(d) = 30;
+---------------------+
| d                   |
+---------------------+
| 2007-01-30 21:31:07 |
| 2011-10-30 06:31:41 |
| 2011-01-30 14:03:25 |
+---------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

DAYOFWEEK

Syntax

```
DAYOFWEEK(date)
```

Description

Returns the day of the week index for the date (1 = Sunday, 2 = Monday, …, 7 = Saturday). These index values correspond to the ODBC standard.

This contrasts with WEEKDAY() which follows a different index numbering (`0` = Monday, `1` = Tuesday, … `6` = Sunday).

Examples

```
SELECT DAYOFWEEK('2007-02-03');
+-------------------------+
| DAYOFWEEK('2007-02-03') |
+-------------------------+
|                       7 |
+-------------------------+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
SELECT d, DAYNAME(d), DAYOFWEEK(d), WEEKDAY(d) from t1;
+---------------------+------------+--------------+------------+
| d                   | DAYNAME(d) | DAYOFWEEK(d) | WEEKDAY(d) |
+---------------------+------------+--------------+------------+
| 2007-01-30 21:31:07 | Tuesday    |            3 |          1 |
| 1983-10-15 06:42:51 | Saturday   |            7 |          5 |
| 2011-04-21 12:34:56 | Thursday   |            5 |          3 |
| 2011-10-30 06:31:41 | Sunday     |            1 |          6 |
| 2011-01-30 14:03:25 | Sunday     |            1 |          6 |
| 2004-10-07 11:19:34 | Thursday   |            5 |          3 |
+---------------------+------------+--------------+------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

DAYOFYEAR

Syntax

```
DAYOFYEAR(date)
```

Description

Returns the day of the year for date, in the range 1 to 366.

Examples

```
SELECT DAYOFYEAR('2018-02-16');
+-------------------------+
| DAYOFYEAR('2018-02-16') |
+-------------------------+
|                      47 |
+-------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

EXTRACT

Syntax

```
EXTRACT(unit FROM date)
```

Description

The EXTRACT() function extracts the required unit from the date. See Date and Time Units for a complete list of permitted units.

HOUR() is not a standard SQL function, so continues to adhere to the old behavior inherited from MySQL.

Examples

```
SELECT EXTRACT(YEAR FROM '2009-07-02');
+--------------------------------+
| EXTRACT(YEAR FROM '2009-07-02') |
+--------------------------------+
|                           2009 |
+--------------------------------+

SELECT EXTRACT(YEAR_MONTH FROM '2009-07-02 01:02:03');
+-----------------------------------------------+
| EXTRACT(YEAR_MONTH FROM '2009-07-02 01:02:03') |
+-----------------------------------------------+
|                                        200907 |
+-----------------------------------------------+

SELECT EXTRACT(DAY_MINUTE FROM '2009-07-02 01:02:03');
+---------------------------------------------+
| EXTRACT(DAY_MINUTE FROM '2009-07-02 01:02:03') |
+---------------------------------------------+
|                                       20102 |
+---------------------------------------------+

SELECT EXTRACT(MICROSECOND FROM '2003-01-02 10:30:00.000123');
+-------------------------------------------------------+
| EXTRACT(MICROSECOND FROM '2003-01-02 10:30:00.000123') |
+-------------------------------------------------------+
|                                                   123 |
+-------------------------------------------------------+
```

`EXTRACT (HOUR FROM...)` returns a value from 0 to 23, as per the SQL standard. `HOUR` is not a standard function, so continues to adhere to the old behaviour inherited from MySQL.

```
SELECT EXTRACT(HOUR FROM '26:30:00'), HOUR('26:30:00');
+-------------------------------+------------------+
| EXTRACT(HOUR FROM '26:30:00') | HOUR('26:30:00') |
+-------------------------------+------------------+
|                             2 |               26 |
+-------------------------------+------------------+
```

- HOUR()

This page is licensed: GPLv2, originally from fill_help_tables.sql

FORMAT_PICO_TIME

> **Note:**
>
> FORMAT_PICO_TIME is available from MariaDB 11.0.2.

Syntax

```
FORMAT_PICO_TIME(time_val)
```

Description

Given a time in picoseconds, returns a human-readable time value and unit indicator. Resulting unit is dependent on the length of the argument, and can be:

- ps - picoseconds
- ns - nanoseconds
- us - microseconds
- ms - milliseconds
- s - seconds
- min - minutes
- h - hours
- d - days

With the exception of results under one nanosecond, which are not rounded and are represented as whole numbers, the result is rounded to 2 decimal places, with a minimum of 3 significant digits.

Returns NULL if the argument is NULL.

This function is very similar to the Sys Schema FORMAT_TIME function, but with the following differences:

- Represents minutes as `min` rather than `m`.
- Does not represent weeks.

Examples

```
SELECT
    FORMAT_PICO_TIME(43) AS ps,
    FORMAT_PICO_TIME(4321) AS ns,
    FORMAT_PICO_TIME(43211234) AS us,
    FORMAT_PICO_TIME(432112344321) AS ms,
    FORMAT_PICO_TIME(43211234432123) AS s,
    FORMAT_PICO_TIME(432112344321234) AS m,
    FORMAT_PICO_TIME(4321123443212345) AS h,
    FORMAT_PICO_TIME(432112344321234545) AS d;
+--------+---------+----------+-----------+---------+----------+--------+--------+
| ps     | ns      | us       | ms        | s       | m        | h      | d      |
+--------+---------+----------+-----------+---------+----------+--------+--------+
|  43 ps | 4.32 ns | 43.21 us | 432.11 ms | 43.21 s | 7.20 min | 1.20 h | 5.00 d |
+--------+---------+----------+-----------+---------+----------+--------+--------+
```

This page is licensed: CC BY-SA / Gnu FDL

FROM_DAYS

Syntax

```
FROM_DAYS(N)
```

Description

Given a day number N, returns a DATE value. The day count is based on the number of days from the start of the standard calendar (0000-00-00).

The function is not designed for use with dates before the advent of the Gregorian calendar in October 1582. Results will not be reliable since it doesn't account for the lost days when the calendar changed from the Julian calendar.

This is the converse of the TO_DAYS() function.

Examples

```
SELECT FROM_DAYS(730669);
+-------------------+
| FROM_DAYS(730669) |
+-------------------+
| 2000-07-03        |
+-------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

FROM_UNIXTIME

Syntax

```
FROM_UNIXTIME(unix_timestamp)
FROM_UNIXTIME(unix_timestamp,format)
```

Description

Converts the number of seconds from the epoch (1970-01-01 00:00:00 UTC) to a `TIMESTAMP` value, the opposite of what UNIX_TIMESTAMP() is doing. Returns NULL if the result would be outside of the valid range of `TIMESTAMP` values.

If format is given, the result is exactly equivalent to

```
DATE_FORMAT(FROM_UNIXTIME(unix_timestamp), format)
```

CURRENT

Timestamps in MariaDB have a maximum value of 4294967295, equivalent to `2106-02-07 06:28:15`. This is due to the underlying 32-bit limitation. Using the function on a timestamp beyond this will result in NULL being returned. Use DATETIME as a storage type if you require dates beyond this.

< 11.7

The one-argument form of `FROM_UNIXTIME()` returns a `DATETIME`. This means that it can return values outside of valid `TIMESTAMP` range, in particular `1970-01-01 00:00:00`. And it can return the same result for different values of unix_timestamp (around DST changes).

Timestamps in MariaDB have a maximum value of 4294967295, equivalent to `2106-02-07 06:28:15`. This is due to the underlying 32-bit limitation. Using the function on a timestamp beyond this will result in NULL being returned. Use DATETIME as a storage type if you require dates beyond this.

< 11.5

The one-argument form of `FROM_UNIXTIME()` returns a `DATETIME`. This means that it can return values outside of valid `TIMESTAMP` range, in particular `1970-01-01 00:00:00`. And it can return the same result for different values of unix_timestamp (around DST changes).

The maximum value is 2147483647, equivalent to `2038-01-19 05:14:07`.

The following options can be used by `FROM_UNIXTIME()`, as well as DATE_FORMAT() and STR_TO_DATE():

Option	Description
%a	Short weekday name in current locale (Variable lc_time_names).
%b	Short form month name in current locale. For locale en_US this is one of: Jan,Feb,Mar,Apr,May,Jun,Jul,Aug,Sep,Oct,Nov or Dec.

Option	Description
%c	Month with 1 or 2 digits.
%D	Day with English suffix ‘th’, ‘nd’, ‘st’ or ‘rd’’. (1st, 2nd, 3rd…).
%d	Day with 2 digits.
%e	Day with 1 or 2 digits.
%f	Microseconds 6 digits.
%H	Hour with 2 digits between 00-23.
%h	Hour with 2 digits between 01-12.
%I	Hour with 2 digits between 01-12.
%i	Minute with 2 digits.
%j	Day of the year (001-366)
%k	Hour with 1 digits between 0-23.
%l	Hour with 1 digits between 1-12.
%M	Full month name in current locale (Variable lc_time_names).
%m	Month with 2 digits.
%p	AM/PM according to current locale (Variable lc_time_names).
%r	Time in 12 hour format, followed by AM/PM. Short for ‘%I:%i:%S %p’.
%S	Seconds with 2 digits.
%s	Seconds with 2 digits.
%T	Time in 24 hour format. Short for ‘%H:%i:%S’.
%U	Week number (00-53), when first day of the week is Sunday.
%u	Week number (00-53), when first day of the week is Monday.
%V	Week number (01-53), when first day of the week is Sunday. Used with %X.
%v	Week number (01-53), when first day of the week is Monday. Used with %x.
%W	Full weekday name in current locale (Variable lc_time_names).
%w	Day of the week. 0 = Sunday, 6 = Saturday.
%X	Year with 4 digits when first day of the week is Sunday. Used with %V.
%x	Year with 4 digits when first day of the week is Sunday. Used with %v.
%Y	Year with 4 digits.
%y	Year with 2 digits.
%#	For str_to_date(), skip all numbers.
%.	For str_to_date(), skip all punctuation characters.
%@	For str_to_date(), skip all alpha characters.
%%	A literal % character.

Performance Considerations

If your session time zone is set to `SYSTEM` (the default), `FROM_UNIXTIME()` will call the OS function to convert the data using the system time zone. At least on Linux, the corresponding function (`localtime_r`) uses a global mutex inside glibc that can cause contention under high concurrent load.

Set your time zone to a named time zone to avoid this issue. See mysql time zone tables for details on how to do this.

Examples

```
SELECT FROM_UNIXTIME(1196440219);
+---------------------------+
| FROM_UNIXTIME(1196440219) |
+---------------------------+
| 2007-11-30 11:30:19       |
+---------------------------+

SELECT FROM_UNIXTIME(1196440219) + 0;
+-------------------------------+
| FROM_UNIXTIME(1196440219) + 0 |
+-------------------------------+
|         20071130113019.000000 |
+-------------------------------+

SELECT FROM_UNIXTIME(UNIX_TIMESTAMP(), '%Y %D %M %h:%i:%s %x');
+-----------------------------------------------------------+
| FROM_UNIXTIME(UNIX_TIMESTAMP(), '%Y %D %M %h:%i:%s %x') |
+-----------------------------------------------------------+
| 2010 27th March 01:03:47 2010                             |
+-----------------------------------------------------------+
```

- DATE_FORMAT()
- STR_TO_DATE()

This page is licensed: GPLv2, originally from fill_help_tables.sql

GET_FORMAT

Syntax

```
GET_FORMAT({DATE|DATETIME|TIME}, {'EUR'|'USA'|'JIS'|'ISO'|'INTERNAL'})
```

Description

Returns a format string. This function is useful in combination with the DATE_FORMAT() and the STR_TO_DATE() functions.

Possible result formats are:

Function Call	Result Format
GET_FORMAT(DATE,‘EUR’)	‘%d.%m.%Y’
GET_FORMAT(DATE,‘USA’)	‘%m.%d.%Y’
GET_FORMAT(DATE,‘JIS’)	‘%Y-%m-%d’
GET_FORMAT(DATE,‘ISO’)	‘%Y-%m-%d’
GET_FORMAT(DATE,‘INTERNAL’)	‘%Y%m%d’
GET_FORMAT(DATETIME,‘EUR’)	‘%Y-%m-%d %H.%i.%s’
GET_FORMAT(DATETIME,‘USA’)	‘%Y-%m-%d %H.%i.%s’
GET_FORMAT(DATETIME,‘JIS’)	‘%Y-%m-%d %H:%i:%s’
GET_FORMAT(DATETIME,‘ISO’)	‘%Y-%m-%d %H:%i:%s’
GET_FORMAT(DATETIME,‘INTERNAL’)	‘%Y%m%d%H%i%s’
GET_FORMAT(TIME,‘EUR’)	‘%H.%i.%s’

Function Call	Result Format
GET_FORMAT(TIME,‘USA’)	‘%h:%i:%s %p’
GET_FORMAT(TIME,‘JIS’)	‘%H:%i:%s’
GET_FORMAT(TIME,‘ISO’)	‘%H:%i:%s’
GET_FORMAT(TIME,‘INTERNAL’)	‘%H%i%s’

Examples

Obtaining the string matching to the standard European date format:

```
SELECT GET_FORMAT(DATE, 'EUR');
+-------------------------+
| GET_FORMAT(DATE, 'EUR') |
+-------------------------+
| %d.%m.%Y                |
+-------------------------+
```

Using the same string to format a date:

```
SELECT DATE_FORMAT('2003-10-03',GET_FORMAT(DATE,'EUR'));
+------------------------------------------------+
| DATE_FORMAT('2003-10-03',GET_FORMAT(DATE,'EUR')) |
+------------------------------------------------+
| 03.10.2003                                     |
+------------------------------------------------+

SELECT STR_TO_DATE('10.31.2003',GET_FORMAT(DATE,'USA'));
+------------------------------------------------+
| STR_TO_DATE('10.31.2003',GET_FORMAT(DATE,'USA')) |
+------------------------------------------------+
| 2003-10-31                                     |
+------------------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

HOUR

Syntax

```
HOUR(time)
```

Description

Returns the hour for time. The range of the return value is 0 to 23 for time-of-day values. However, the range of `TIME` values actually is much larger, so HOUR can return values greater than 23.

The return value is always positive, even if a negative `TIME` value is provided.

Examples

```
SELECT HOUR('10:05:03');
+------------------+
| HOUR('10:05:03') |
+------------------+
|               10 |
+------------------+

SELECT HOUR('272:59:59');
+-------------------+
| HOUR('272:59:59') |
+-------------------+
|               272 |
+-------------------+
```

- Date and Time Literals
- EXTRACT()

This page is licensed: GPLv2, originally from fill_help_tables.sql

LAST_DAY

Syntax

```
LAST_DAY(date)
```

Description

Takes a date or datetime value and returns the corresponding value for the last day of the month. Returns `NULL` if the argument is invalid.

Examples

```
SELECT LAST_DAY('2003-02-05');
+------------------------+
| LAST_DAY('2003-02-05') |
+------------------------+
| 2003-02-28             |
+------------------------+

SELECT LAST_DAY('2004-02-05');
+------------------------+
| LAST_DAY('2004-02-05') |
+------------------------+
| 2004-02-29             |
+------------------------+

SELECT LAST_DAY('2004-01-01 01:01:01');
+---------------------------------+
| LAST_DAY('2004-01-01 01:01:01') |
+---------------------------------+
| 2004-01-31                      |
+---------------------------------+

SELECT LAST_DAY('2003-03-32');
+------------------------+
| LAST_DAY('2003-03-32') |
+------------------------+
| NULL                   |
+------------------------+
1 row in set, 1 warning (0.00 sec)

Warning (Code 1292): Incorrect datetime value: '2003-03-32'
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

LOCALTIME

Syntax

```
LOCALTIME
LOCALTIME([precision])
```

Description

`LOCALTIME` and `LOCALTIME()` are synonyms for NOW().

See Also

- Microseconds in MariaDB

This page is licensed: GPLv2, originally from fill_help_tables.sql

LOCALTIMESTAMP

Syntax

```
LOCALTIMESTAMP
LOCALTIMESTAMP([precision])
```

Description

`LOCALTIMESTAMP` and `LOCALTIMESTAMP()` are synonyms for NOW().

See Also

- Microseconds in MariaDB

This page is licensed: GPLv2, originally from fill_help_tables.sql

MAKEDATE

Syntax

```
MAKEDATE(year,dayofyear)
```

Description

Returns a date, given `year` and `day-of-year values`. `dayofyear` must be greater than 0 or the result is `NULL`.

Examples

```
SELECT MAKEDATE(2011,31), MAKEDATE(2011,32);
+------------------+------------------+
| MAKEDATE(2011,31) | MAKEDATE(2011,32) |
+------------------+------------------+
| 2011-01-31        | 2011-02-01        |
+------------------+------------------+
```

2012 is a leap year:

```
SELECT MAKEDATE(2011,365), MAKEDATE(2012,365);
+------------------+------------------+
| MAKEDATE(2011,365) | MAKEDATE(2012,365) |
+------------------+------------------+
| 2011-12-31         | 2012-12-30         |
+------------------+------------------+

SELECT MAKEDATE(2011,366), MAKEDATE(2012,366);
+------------------+------------------+
| MAKEDATE(2011,366) | MAKEDATE(2012,366) |
+------------------+------------------+
| 2012-01-01         | 2012-12-31         |
+------------------+------------------+

SELECT MAKEDATE(2011,0);
+-----------------+
| MAKEDATE(2011,0) |
+-----------------+
| NULL             |
+-----------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

MAKETIME

Syntax

```
MAKETIME(hour,minute,second)
```

Description

Returns a time value calculated from the `hour`, `minute`, and `second` arguments.

If `minute` or `second` are out of the range 0 to 60, `NULL` is returned. The `hour` can be in the range -838 to 838, outside of which the value is truncated with a warning.

Examples

```
SELECT MAKETIME(13,57,33);
+--------------------+
| MAKETIME(13,57,33) |
+--------------------+
| 13:57:33           |
+--------------------+

SELECT MAKETIME(-13,57,33);
+---------------------+
| MAKETIME(-13,57,33) |
+---------------------+
| -13:57:33           |
+---------------------+

SELECT MAKETIME(13,67,33);
+--------------------+
| MAKETIME(13,67,33) |
+--------------------+
| NULL               |
+--------------------+

SELECT MAKETIME(-1000,57,33);
+-----------------------+
| MAKETIME(-1000,57,33) |
+-----------------------+
| -838:59:59            |
+-----------------------+
1 row in set, 1 warning (0.00 sec)

SHOW WARNINGS;
+---------+------+-----------------------------------------------+
| Level   | Code | Message                                       |
+---------+------+-----------------------------------------------+
| Warning | 1292 | Truncated incorrect time value: '-1000:57:33' |
+---------+------+-----------------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

MICROSECOND

Syntax

```
MICROSECOND(expr)
```

Description

Returns the microseconds from the time or datetime expression *expr* as a number in the range from 0 to 999999.

If *expr* is a time with no microseconds, zero is returned, while if *expr* is a date with no time, zero with a warning is returned.

Examples

```
SELECT MICROSECOND('12:00:00.123456');
+-------------------------------+
| MICROSECOND('12:00:00.123456') |
+-------------------------------+
|                        123456 |
+-------------------------------+

SELECT MICROSECOND('2009-12-31 23:59:59.000010');
+----------------------------------------+
| MICROSECOND('2009-12-31 23:59:59.000010') |
+----------------------------------------+
|                                     10 |
+----------------------------------------+

SELECT MICROSECOND('2013-08-07 12:13:14');
+-----------------------------------+
| MICROSECOND('2013-08-07 12:13:14') |
+-----------------------------------+
|                                 0 |
+-----------------------------------+

SELECT MICROSECOND('2013-08-07');
+---------------------------+
| MICROSECOND('2013-08-07') |
+---------------------------+
|                         0 |
+---------------------------+
1 row in set, 1 warning (0.00 sec)

SHOW WARNINGS;
+---------+------+-----------------------------------------------+
| Level   | Code | Message                                       |
+---------+------+-----------------------------------------------+
| Warning | 1292 | Truncated incorrect time value: '2013-08-07' |
+---------+------+-----------------------------------------------+
```

- Microseconds in MariaDB

This page is licensed: GPLv2, originally from fill_help_tables.sql

Microseconds in MariaDB

The TIME, DATETIME, and TIMESTAMP types, along with the temporal functions, CAST and dynamic columns, support microseconds. The datetime precision of a column can be specified when creating the table with CREATE TABLE, for example:

```
CREATE TABLE example(
  col_microsec DATETIME(6),
  col_millisec TIME(3)
);
```

Generally, the precision can be specified for any `TIME`, `DATETIME`, or `TIMESTAMP` column, in parentheses, after the type name. The datetime precision specifies number of digits after the decimal dot and can be any integer number from 0 to 6. If no precision is specified it is assumed to be 0, for backward compatibility reasons.

A datetime precision can be specified wherever a type name is used. For example:

- when declaring arguments of stored routines;
- when specifying a return type of a stored function;
- when declaring variables;

- in a `CAST` function.

```
CREATE FUNCTION example(x DATETIME(5)) RETURNS TIME(4)
BEGIN
 DECLARE y TIMESTAMP(6);
 RETURN CAST(x AS time(2));
END;
```

`%f` is used as the formatting option for microseconds in the STR_TO_DATE, DATE_FORMAT and FROM_UNIXTIME functions, for example:

```
SELECT STR_TO_DATE('20200809 020917076','%Y%m%d %H%i%s%f');
+-----------------------------------------------------+
| STR_TO_DATE('20200809 020917076','%Y%m%d %H%i%s%f') |
+-----------------------------------------------------+
| 2020-08-09 02:09:17.076000                          |
+-----------------------------------------------------+
```

Additional Information

- When comparing anything to a temporal value (`DATETIME`, `TIME`, DATE, or `TIMESTAMP`), both values are compared as temporal values, not as strings.
- The INFORMATION_SCHEMA.COLUMNS table has a new column `DATETIME_PRECISION`
- NOW(), CURTIME(), UTC_TIMESTAMP(), UTC_TIME(), CURRENT_TIME(), CURRENT_TIMESTAMP(), LOCALTIME() and LOCALTIMESTAMP() accept datetime precision as an optional argument. For example:

```
SELECT CURTIME(4);
--> 10:11:12.3456
```

- TIME_TO_SEC() and UNIX_TIMESTAMP() preserve microseconds of the argument. These functions will return a decimal number if the result non-zero datetime precision and an integer otherwise (for backward compatibility).

```
SELECT TIME_TO_SEC('10:10:10.12345');
--> 36610.12345
```

- Current versions of this patch fix a bug in the following optimization: In certain queries with `DISTINCT` MariaDB can ignore this clause if it can prove that all result rows are unique anyway, for example, when a primary key is compared with a constant. Sometimes this optimization was applied incorrectly, though — for example, when comparing a string with a date constant. This is now fixed.
- `DATE_ADD()` and `DATE_SUB()` functions can now take a `TIME` expression as an argument (not just `DATETIME` as before).

```
SELECT TIME('10:10:10') + INTERVAL 100 MICROSECOND;
--> 10:10:10.000100
```

- The `event_time` field in the mysql.general_log table and the `start_time`, `query_time`, and `lock_time` fields in the mysql.slow_log table now store values with microsecond precision.
- The old syntax `TIMESTAMP(N)`, where `N` is the display width, is no longer supported.
- When a `DATETIME` value is compared to a `TIME` value, the latter is treated as a full datetime with a zero date part, similar to comparing `DATE` to a `DATETIME`, or to comparing `DECIMAL` numbers.
  Earlier versions of MariaDB used to compare only the time part of both operands in such a case.
- In MariaDB, an extra column TIME_MS has been added to the INFORMATION_SCHEMA.PROCESSLIST table, as well as to the output of SHOW FULL PROCESSLIST.

Note: When you convert a temporal value to a value with a smaller precision, it will be truncated, not rounded. This is done to guarantee that the date part is not changed. For example:

```
SELECT CAST('2009-12-31 23:59:59.998877' AS DATETIME(3));
-> 2009-12-31 23:59:59.998
```

See Also

- Data Type Storage Requirements

This page is licensed: CC BY-SA / Gnu FDL

MINUTE

Syntax

```
MINUTE(time)
```

Description

Returns the minute for *time*, in the range 0 to 59.

Examples

```
SELECT MINUTE('2013-08-03 11:04:03');
+------------------------------+
| MINUTE('2013-08-03 11:04:03') |
+------------------------------+
|                            4 |
+------------------------------+

 SELECT MINUTE ('23:12:50');
+---------------------+
| MINUTE ('23:12:50') |
+---------------------+
|                  12 |
+---------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

MONTH

Syntax

```
MONTH(date)
```

Description

Returns the month for `date` in the range 1 to 12 for January to December, or 0 for dates such as `0000-00-00` or `2008-00-00` that have a zero month part.

Examples

```
SELECT MONTH('2019-01-03');
+---------------------+
| MONTH('2019-01-03') |
+---------------------+
|                   1 |
+---------------------+

SELECT MONTH('2019-00-03');
+---------------------+
| MONTH('2019-00-03') |
+---------------------+
|                   0 |
+---------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

MONTHNAME

Syntax

```
MONTHNAME(date)
```

Description

Returns the full name of the month for date. The language used for the name is controlled by the value of the lc_time_names system variable. See server locale for more on the supported locales.

Examples

```
SELECT MONTHNAME('2019-02-03');
+-------------------------+
| MONTHNAME('2019-02-03') |
+-------------------------+
| February                |
+-------------------------+
```

Changing the locale:

```
SET lc_time_names = 'fr_CA';

SELECT MONTHNAME('2019-05-21');
+-------------------------+
| MONTHNAME('2019-05-21') |
+-------------------------+
| mai                     |
+-------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

MONTHS_BETWEEN

`MONTHS_BETWEEN` returns the number of months between dates two dates. If the first date given is later than the second date, the result is positive; otherwise, the result is negative. If both dates are the same days of the month, or both are last days of months, the result is always an integer. Otherwise, the fractional portion of the result based on a 31-day month is calculated, and considered the difference in time components between the dates.

The following example calculates the months between two dates:

```
SELECT MONTHS_BETWEEN
       (TO_DATE('02-02-1995','MM-DD-YYYY'),
        TO_DATE('01-01-1995','MM-DD-YYYY')
       );
```

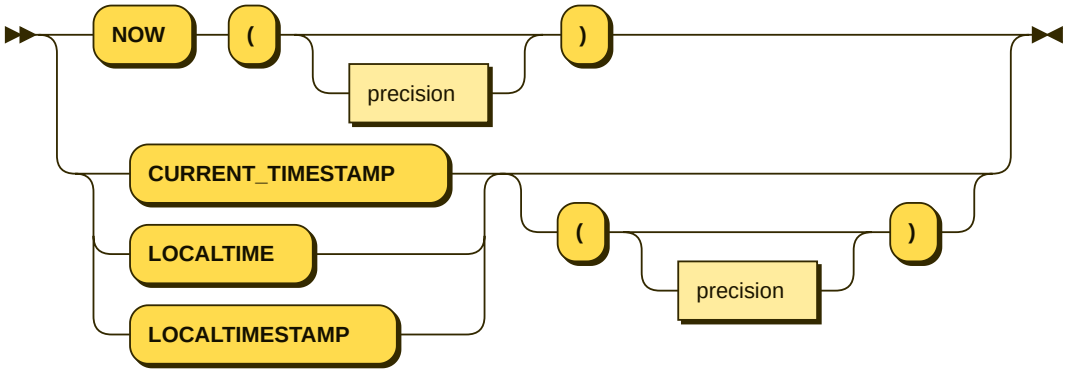
The result is `1.03225806`.

This page is licensed: CC BY-SA / Gnu FDL

NOW

Syntax

```
NOW([precision])
CURRENT_TIMESTAMP
CURRENT_TIMESTAMP([precision])
LOCALTIME
LOCALTIME([precision])
LOCALTIMESTAMP
LOCALTIMESTAMP([precision])
```



Railroad diagram of NOW and synonyms — equivalent to the BNF above

Description

Returns the current date and time as a value in `YYYY-MM-DD HH:MM:SS` or `YYYYMMDDHHMMSS.uuuuuu` format, depending on whether the function is used in a string or numeric context. The value is expressed in the current time zone.

MariaDB starting with 11.7

CURRENT

These functions return SQL standard compliant types:

- `NOW()` and `CURRENT_TIMESTAMP()` return a `TIMESTAMP` value (analogous to the standard type `TIMESTAMP WITH LOCAL TIME ZONE`) which corresponds to the current point in time and is unambiguous around DST changes.
- `LOCALTIMESTAMP` returns a `DATETIME` value (analogous to the standard type `TIMESTAMP WITHOUT TIME ZONE`). Storing its result in a `TIMESTAMP` column can result in a data loss around DST changes.

< 11.7

These functions do **not** return SQL standard compliant types:

- `NOW()`
- `CURRENT_TIMESTAMP()`

- `LOCALTIMESTAMP`

The optional *precision* determines the microsecond precision. See Microseconds in MariaDB.

`NOW()` (or its synonyms) can be used as the default value for TIMESTAMP columns as well as.

When displayed in the INFORMATION_SCHEMA.COLUMNS table, a default CURRENT TIMESTAMP is displayed as `current_timestamp()` .

Changing the timestamp system variable with a SET `timestamp` statement affects the value returned by `NOW()`, but not by SYSDATE().

Examples

```
SELECT NOW();
+---------------------+
| NOW()               |
+---------------------+
| 2010-03-27 13:13:25 |
+---------------------+

SELECT NOW() + 0;
+-----------------------+
| NOW() + 0             |
+-----------------------+
| 20100327131329.000000 |
+-----------------------+
```

With precision:

```
SELECT CURRENT_TIMESTAMP(2);
+------------------------+
| CURRENT_TIMESTAMP(2)   |
+------------------------+
| 2018-07-10 09:47:26.24 |
+------------------------+
```

Used as a default TIMESTAMP:

```
CREATE TABLE t (createdTS TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP);
```

```
SELECT * FROM INFORMATION_SCHEMA.COLUMNS WHERE TABLE_SCHEMA='test'
  AND COLUMN_NAME LIKE '%ts%'\G
*************************** 1. row ***************************
           TABLE_CATALOG: def
            TABLE_SCHEMA: test

PERIOD_ADD

Syntax

```
PERIOD_ADD(P,N)
```

Description

Adds `N` months to period `P`. `P` is in the format YYMM or YYYYMM, and is not a date value. If `P` contains a two-digit year, values from 00 to 69 are converted to from 2000 to 2069, while values from 70 are converted to 1970 upwards.

Returns a value in the format `YYYYMM`.

Examples

```
SELECT PERIOD_ADD(200801,2);
+----------------------+
| PERIOD_ADD(200801,2) |
+----------------------+
|               200803 |
+----------------------+

SELECT PERIOD_ADD(6910,2);
+--------------------+
| PERIOD_ADD(6910,2) |
+--------------------+
|             206912 |
+--------------------+

SELECT PERIOD_ADD(7010,2);
+--------------------+
| PERIOD_ADD(7010,2) |
+--------------------+
|             197012 |
+--------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

PERIOD_DIFF

Syntax

```
PERIOD_DIFF(P1,P2)
```

Description

Returns the number of months between periods P1 and P2. P1 and P2 can be in the format `YYMM` or `YYYYMM`, and are not date values.

If P1 or P2 contains a two-digit year, values from 00 to 69 are converted to from 2000 to 2069, while values from 70 are converted to 1970 upwards.

Examples

```
SELECT PERIOD_DIFF(200802,200703);
+----------------------------+
| PERIOD_DIFF(200802,200703) |
+----------------------------+
|                         11 |
+----------------------------+

SELECT PERIOD_DIFF(6902,6803);
+------------------------+
| PERIOD_DIFF(6902,6803) |
+------------------------+
|                     11 |
+------------------------+

SELECT PERIOD_DIFF(7002,6803);
+------------------------+
| PERIOD_DIFF(7002,6803) |
+------------------------+
|                  -1177 |
+------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

QUARTER

Syntax

```
QUARTER(date)
```

Description

Returns the quarter of the year for `date`, in the range 1 to 4. Returns 0 if month contains a zero value, or `NULL` if the given value is not otherwise a valid date (zero values are accepted).

Examples

```
SELECT QUARTER('2008-04-01');
+-----------------------+
| QUARTER('2008-04-01') |
+-----------------------+
|                     2 |
+-----------------------+

SELECT QUARTER('2019-00-01');
+-----------------------+
| QUARTER('2019-00-01') |
+-----------------------+
|                     0 |
+-----------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

SEC_TO_TIME

Syntax

```
SEC_TO_TIME(seconds)
```

Description

Returns the seconds argument, converted to hours, minutes, and seconds, as a TIME value. The range of the result is constrained to that of the TIME data type. A warning occurs if the argument corresponds to a value outside that range.

The time will be returned in the format `hh:mm:ss`, or `hhmmss` if used in a numeric calculation.

Examples

```
SELECT SEC_TO_TIME(12414);
+-------------------+
| SEC_TO_TIME(12414) |
+-------------------+
| 03:26:54          |
+-------------------+

SELECT SEC_TO_TIME(12414)+0;
+----------------------+
| SEC_TO_TIME(12414)+0 |
+----------------------+
|                32654 |
+----------------------+

SELECT SEC_TO_TIME(9999999);
+----------------------+
| SEC_TO_TIME(9999999) |
+----------------------+
| 838:59:59            |
+----------------------+
1 row in set, 1 warning (0.00 sec)

SHOW WARNINGS;
+---------+------+-------------------------------------------+
| Level   | Code | Message                                   |
+---------+------+-------------------------------------------+
| Warning | 1292 | Truncated incorrect time value: '9999999' |
+---------+------+-------------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

SECOND

Syntax

```
SECOND(time)
```

Description

Returns the second for a given `time` (which can include microseconds), in the range 0 to 59, or `NULL` if not given a valid time value.

Examples

```
SELECT SECOND('10:05:03');
+-------------------+
| SECOND('10:05:03') |
+-------------------+
|                  3 |
+-------------------+

SELECT SECOND('10:05:01.999999');
+--------------------------+
| SECOND('10:05:01.999999') |
+--------------------------+
|                        1 |
+--------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

STR_TO_DATE

Syntax

```
STR_TO_DATE(str,format)
```

Description

This is the inverse of the DATE_FORMAT() function. It takes a string `str` and a format string `format`. `STR_TO_DATE()` returns a `DATETIME` value if the format string contains both date and time parts, or a `DATE` or `TIME` value if the string contains only date or time parts.

The date, time, or datetime values contained in `str` should be given in the format indicated by format. If str contains an illegal date, time, or datetime value, `STR_TO_DATE()` returns `NULL`. An illegal value also produces a warning.

Under specific SQL_MODE settings an error may also be generated if the `str` isn't a valid date:

- ALLOW_INVALID_DATES
- NO_ZERO_DATE
- NO_ZERO_IN_DATE

The options that can be used by STR_TO_DATE(), as well as its inverse DATE_FORMAT() and the FROM_UNIXTIME() function, are:

Option	Description
%a	Short weekday name in current locale (Variable lc_time_names).
%b	Short form month name in current locale. For locale en_US this is one of: Jan,Feb,Mar,Apr,May,Jun,Jul,Aug,Sep,Oct,Nov or Dec.
%c	Month with 1 or 2 digits.
%D	Day with English suffix 'th', 'nd', 'st' or 'rd''. (1st, 2nd, 3rd…).
%d	Day with 2 digits.
%e	Day with 1 or 2 digits.
%f	Microseconds 6 digits.
%H	Hour with 2 digits between 00-23.
%h	Hour with 2 digits between 01-12.
%I	Hour with 2 digits between 01-12.
%i	Minute with 2 digits.

Option	Description
%j	Day of the year (001-366)
%k	Hour with 1 digits between 0-23.
%l	Hour with 1 digits between 1-12.
%M	Full month name in current locale (Variable lc_time_names).
%m	Month with 2 digits.
%p	AM/PM according to current locale (Variable lc_time_names).
%r	Time in 12 hour format, followed by AM/PM. Short for '%I:%i:%S %p'.
%S	Seconds with 2 digits.
%s	Seconds with 2 digits.
%T	Time in 24 hour format. Short for '%H:%i:%S'.
%U	Week number (00-53), when first day of the week is Sunday.
%u	Week number (00-53), when first day of the week is Monday.
%V	Week number (01-53), when first day of the week is Sunday. Used with %X.
%v	Week number (01-53), when first day of the week is Monday. Used with %x.
%W	Full weekday name in current locale (Variable lc_time_names).
%w	Day of the week. 0 = Sunday, 6 = Saturday.
%X	Year with 4 digits when first day of the week is Sunday. Used with %V.
%x	Year with 4 digits when first day of the week is Monday. Used with %v.
%Y	Year with 4 digits.
%y	Year with 2 digits.
%#	For str_to_date(), skip all numbers.
%.	For str_to_date(), skip all punctuation characters.
%@	For str_to_date(), skip all alpha characters.
%%	A literal % character.

Examples

```
SELECT STR_TO_DATE('Wednesday, June 2, 2014', '%W, %M %e, %Y');
+-------------------------------------------------------+
| STR_TO_DATE('Wednesday, June 2, 2014', '%W, %M %e, %Y') |
+-------------------------------------------------------+
| 2014-06-02                                            |
+-------------------------------------------------------+

SELECT STR_TO_DATE('Wednesday23423, June 2, 2014', '%W, %M %e, %Y');
+-------------------------------------------------------------+
| STR_TO_DATE('Wednesday23423, June 2, 2014', '%W, %M %e, %Y') |
+-------------------------------------------------------------+
| NULL                                                        |
+-------------------------------------------------------------+
1 row in set, 1 warning (0.00 sec)

SHOW WARNINGS;

SUBDATE

Syntax

```
SUBDATE(date,INTERVAL expr unit), SUBDATE(expr,days)
```

Description

When invoked with the `INTERVAL` form of the second argument, `SUBDATE()` is a synonym for DATE_SUB(). See Date and Time Units for a complete list of permitted units.

The second form allows the use of an integer value for days. In such cases, it is interpreted as the number of days to be subtracted from the date or datetime expression expr.

Examples

```
SELECT DATE_SUB('2008-01-02', INTERVAL 31 DAY);
+----------------------------------------+
| DATE_SUB('2008-01-02', INTERVAL 31 DAY) |
+----------------------------------------+
| 2007-12-02                             |
+----------------------------------------+

SELECT SUBDATE('2008-01-02', INTERVAL 31 DAY);
+----------------------------------------+
| SUBDATE('2008-01-02', INTERVAL 31 DAY) |
+----------------------------------------+
| 2007-12-02                             |
+----------------------------------------+
```

```
SELECT SUBDATE('2008-01-02 12:00:00', 31);
+-----------------------------------+
| SUBDATE('2008-01-02 12:00:00', 31) |
+-----------------------------------+
| 2007-12-02 12:00:00                |
+-----------------------------------+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),

+---------------------+-------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

SUBTIME

Syntax

```
SUBTIME(expr1,expr2)
```

Description

`SUBTIME()` returns `expr1` - `expr2` expressed as a value in the same format as `expr1`. `expr1` is a time or datetime expression, and expr2 is a time expression.

Examples

```
SELECT SUBTIME('2007-12-31 23:59:59.999999','1 1:1:1.000002');
+----------------------------------------------------------+
| SUBTIME('2007-12-31 23:59:59.999999','1 1:1:1.000002') |
+----------------------------------------------------------+
| 2007-12-30 22:58:58.999997                               |
+----------------------------------------------------------+

SELECT SUBTIME('01:00:00.999999', '02:00:00.999998');
+-----------------------------------------------+
| SUBTIME('01:00:00.999999', '02:00:00.999998') |
+-----------------------------------------------+
| -00:59:59.999999                              |
+-----------------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

SYSDATE

Syntax

```
SYSDATE([precision])
```

Description

Returns the current date and time as a value in `YYYY-MM-DD HH:MM:SS` or `YYYYMMDDHHMMSS.uuuuuu` format, depending on whether the function is used in a string or numeric context.

The optional *precision* determines the microsecond precision. See Microseconds in MariaDB.

`SYSDATE()` returns the time at which it executes. This differs from the behavior for NOW(), which returns a constant time that indicates the time at which the statement began to execute. (Within a stored routine or trigger, NOW() returns the time at which the routine or triggering statement began to execute.)

In addition, changing the timestamp system variable with a SET `timestamp` statement affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`.

Because `SYSDATE()` can return different values even within the same statement, and is not affected by `SET TIMESTAMP`, it is non-deterministic and therefore unsafe for replication if statement-based binary logging is used. If that is a problem, you can use row-based logging, or start the server with the –sysdate-is-now mariadbd option to cause `SYSDATE()` to be an alias for `NOW()`. The non-deterministic nature of `SYSDATE()` also means that indexes cannot be used for evaluating expressions that refer to it, and that statements using the `SYSDATE()` function are unsafe for statement-based replication.

Examples

Difference between `NOW()` and `SYSDATE()`:

```
SELECT NOW(), SLEEP(2), NOW();
+---------------------+----------+---------------------+
| NOW()               | SLEEP(2) | NOW()               |
+---------------------+----------+---------------------+
| 2010-03-27 13:23:40 |        0 | 2010-03-27 13:23:40 |
+---------------------+----------+---------------------+

SELECT SYSDATE(), SLEEP(2), SYSDATE();
+---------------------+----------+---------------------+
| SYSDATE()           | SLEEP(2) | SYSDATE()           |
+---------------------+----------+---------------------+
| 2010-03-27 13:23:52 |        0 | 2010-03-27 13:23:54 |
+---------------------+----------+---------------------+
```

With precision:

```
SELECT SYSDATE(4);
+--------------------------+
| SYSDATE(4)               |
+--------------------------+
| 2018-07-10 10:17:13.1689 |
+--------------------------+
```

See Also

- Microseconds in MariaDB
- timestamp server system variable

This page is licensed: GPLv2, originally from fill_help_tables.sql

TIME

Syntax

```
TIME(expr)
```

Description

Extracts the time part of the time or datetime expression `expr` and returns it as a string.

Examples

```
SELECT TIME('2003-12-31 01:02:03');
+-----------------------------+
| TIME('2003-12-31 01:02:03') |
+-----------------------------+
| 01:02:03                    |
+-----------------------------+

SELECT TIME('2003-12-31 01:02:03.000123');
+----------------------------------+
| TIME('2003-12-31 01:02:03.000123') |
+----------------------------------+
| 01:02:03.000123                  |
+----------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

TIME_FORMAT

Syntax

```
TIME_FORMAT(time,format)
```

Description

This is used like the DATE_FORMAT() function, but the format string may contain format specifiers only for hours, minutes, and seconds. Other specifiers produce a NULL value or 0.

Examples

```
SELECT TIME_FORMAT('100:00:00', '%H %k %h %I %l');
+----------------------------------------+
| TIME_FORMAT('100:00:00', '%H %k %h %I %l') |
+----------------------------------------+
| 100 100 04 04 4                        |
+----------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

TIME_TO_SEC

Syntax

```
TIME_TO_SEC(time)
```

Description

Returns the time argument, converted to seconds.

The value returned by `TIME_TO_SEC` is of type DOUBLE. The returned value preserves microseconds of the argument. See also Microseconds in MariaDB.

Examples

```
SELECT TIME_TO_SEC('22:23:00');
+-------------------------+
| TIME_TO_SEC('22:23:00') |
+-------------------------+
|                   80580 |
+-------------------------+
```

```
SELECT TIME_TO_SEC('00:39:38');
+-------------------------+
| TIME_TO_SEC('00:39:38') |
+-------------------------+
|                    2378 |
+-------------------------+
```

```
SELECT TIME_TO_SEC('09:12:55.2355');
+-----------------------------+
| TIME_TO_SEC('09:12:55.2355') |
+-----------------------------+
|                   33175.2355 |
+-----------------------------+
1 row in set (0.000 sec)
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

TIMEDIFF

Syntax

```
TIMEDIFF(expr1,expr2)
```

Description

TIMEDIFF() returns `expr1` - `expr2` expressed as a time value. `expr1` and `expr2` are time or date-and-time expressions, but both must be of the same type.

Examples

```
SELECT TIMEDIFF('2000:01:01 00:00:00', '2000:01:01 00:00:00.000001');
+----------------------------------------------------------------+
| TIMEDIFF('2000:01:01 00:00:00', '2000:01:01 00:00:00.000001') |
+----------------------------------------------------------------+
| -00:00:00.000001                                               |
+----------------------------------------------------------------+

SELECT TIMEDIFF('2008-12-31 23:59:59.000001', '2008-12-30 01:01:01.000002');
+-------------------------------------------------------------------+
| TIMEDIFF('2008-12-31 23:59:59.000001', '2008-12-30 01:01:01.000002') |
+-------------------------------------------------------------------+
| 46:58:57.999999                                                   |
+-------------------------------------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

TIMESTAMP

> **Note:**
>
> For the timestamp data type, see TIMESTAMP.

Syntax

```
TIMESTAMP(expr), TIMESTAMP(expr1,expr2)
```

Description

With a single argument, this function returns the date or datetime expression `expr` as a datetime value. With two arguments, it adds the time expression `expr2` to the date or datetime expression `expr1` and returns the result as a datetime value.

Examples

```
SELECT TIMESTAMP('2003-12-31');
+-------------------------+
| TIMESTAMP('2003-12-31') |
+-------------------------+
| 2003-12-31 00:00:00     |
+-------------------------+

SELECT TIMESTAMP('2003-12-31 12:00:00','6:30:00');
+-----------------------------------------+
| TIMESTAMP('2003-12-31 12:00:00','6:30:00') |
+-----------------------------------------+
| 2003-12-31 18:30:00                     |
+-----------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

TIMESTAMPADD

Syntax

```
TIMESTAMPADD(unit,interval,datetime_expr)
```

Description

Adds the integer expression interval to the date or datetime expression datetime_expr. The unit for interval is given by the unit argument, which should be one of the following values: `MICROSECOND`, `SECOND`, `MINUTE`, `HOUR`, `DAY`, `WEEK`, `MONTH`, `QUARTER`, or `YEAR`.

The unit value may be specified using one of keywords as shown, or with a prefix of `SQL_TSI_`. For example, `DAY` and `SQL_TSI_DAY` both are allowed.

Examples

```
SELECT TIMESTAMPADD(MINUTE,1,'2003-01-02');
+-------------------------------------+
| TIMESTAMPADD(MINUTE,1,'2003-01-02') |
+-------------------------------------+
| 2003-01-02 00:01:00                 |
+-------------------------------------+

SELECT TIMESTAMPADD(WEEK,1,'2003-01-02');
+----------------------------------+
| TIMESTAMPADD(WEEK,1,'2003-01-02') |
+----------------------------------+
| 2003-01-09                       |
+----------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

TIMESTAMPDIFF

Syntax

```
TIMESTAMPDIFF(unit,datetime_expr1,datetime_expr2)
```

Description

Returns `datetime_expr2 - datetime_expr1`, where `datetime_expr1` and `datetime_expr2` are date or datetime expressions. One expression may be a date and the other a datetime; a date value is treated as a datetime having the time part '00:00:00' where necessary. The unit for the result (an integer) is given by the unit argument. The legal values for unit are the same as those listed in the description of the TIMESTAMPADD() function, that is, `MICROSECOND`, `SECOND`, `MINUTE`, `HOUR`, `DAY`, `WEEK`, `MONTH`, `QUARTER`, or `YEAR`.

`TIMESTAMPDIFF` can also be used to calculate age.

Examples

```
SELECT TIMESTAMPDIFF(MONTH,'2003-02-01','2003-05-01');
+-------------------------------------------------+
| TIMESTAMPDIFF(MONTH,'2003-02-01','2003-05-01') |
+-------------------------------------------------+
|                                               3 |
+-------------------------------------------------+

SELECT TIMESTAMPDIFF(YEAR,'2002-05-01','2001-01-01');
+------------------------------------------------+
| TIMESTAMPDIFF(YEAR,'2002-05-01','2001-01-01') |
+------------------------------------------------+
|                                             -1 |
+------------------------------------------------+

SELECT TIMESTAMPDIFF(MINUTE,'2003-02-01','2003-05-01 12:05:55');
+--------------------------------------------------------+
| TIMESTAMPDIFF(MINUTE,'2003-02-01','2003-05-01 12:05:55') |
+--------------------------------------------------------+
|                                                 128885 |
+--------------------------------------------------------+
```

Calculating age:

```
SELECT CURDATE();
+------------+
| CURDATE()  |
+------------+
| 2019-05-27 |
+------------+

SELECT TIMESTAMPDIFF(YEAR, '1971-06-06', CURDATE()) AS age;
+------+
| age  |
+------+
|   47 |
+------+

SELECT TIMESTAMPDIFF(YEAR, '1971-05-06', CURDATE()) AS age;
+------+
| age  |
+------+
|   48 |
+------+
```

Age as of 2014-08-02:

```
SELECT name, date_of_birth, TIMESTAMPDIFF(YEAR,date_of_birth,'2014-08-02') AS age
  FROM student_details;
+---------+---------------+------+
| name    | date_of_birth | age  |
+---------+---------------+------+
| Chun    | 1993-12-31    |   20 |
| Esben   | 1946-01-01    |   68 |
| Kaolin  | 1996-07-16    |   18 |
| Tatiana | 1988-04-13    |   26 |
+---------+---------------+------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

TO_DATE

> **Note:**
>
> This function is available from MariaDB 12.3.

Syntax

```
TO_DATE(string_expression [DEFAULT string_expression ON CONVERSION ERROR],
        format_string [,NLS_FORMAT_STRING])
```

Description

`TO_DATE` was added for Oracle support.

- `format_string` has the same format elements as TO_CHAR(), except a few elements that are not supported (see below). `TO_DATE()` returns a datetime value.
- The allowed separators are the same as for `TO_CHAR()`: space ( ), tab (`\t`), and any of `!`, `#`, `%`, `'`, `(`, `)`, `*`, `+`, `-`, `.`, `/`, `:`, `;`, `<`, `=`, or `>`.
- `&` can be used if the next character is not a character in the `a-z` or `A-Z` range. `text` indicates a text string that is used verbatim in the format. You cannot use the double-quote (`"`) as a separator.
- `NLS_FORMAT_STRING` supports these options: `NLS_CALENDAR=GREGORIAN` and `NLS_DATE_LANGUAGE=` *`language`*, where *`language`* can be one of the following:
  - All MariaDB short locales, like `en_AU`.
  - The following Oracle language names: ALBANIAN, AMERICAN, ARABIC, BASQUE, BELARUSIAN, BRAZILIAN PORTUGUESE, BULGARIAN, CANADIAN FRENCH, CATALAN, CROATIAN, CYRILLIC SERBIAN, CZECH, DANISH, DUTCH, ENGLISH, ESTONIAN, FINNISH, FRENCH, GERMAN, GREEK, HEBREW, HINDI, HUNGARIAN, ICELANDIC, INDONESIAN, ITALIAN, JAPANESE, KANNADA, KOREAN, LATIN AMERICAN SPANISH, LATVIAN, LITHUANIAN, MACEDONIAN, MALAY, MEXICAN SPANISH, NORWEGIAN, POLISH, PORTUGUESE, ROMANIAN, RUSSIAN, SIMPLIFIED CHINESE, SLOVAK, SLOVENIAN, SPANISH, SWAHILI, SWEDISH, TAMIL, THAI, TRADITIONAL CHINESE, TURKISH, UKRAINIAN, VIETNAMESE

Supported Format Elements

- `AD` – Anno Domini (“in the year of the Lord”)
- `AD_DOT` – Anno Domini (“in the year of the Lord”)
- `AM` – Meridian indicator (before midday)
- `AM_DOT` – Meridian indicator (before midday)
- `DAY` – Name of day
- `DD` – Day (1-31)

- `DDD` – Day of year (1-336)
- `DY` – Abbreviated name of day
- `FF[1-6]` – Fractional seconds
- `HH` – Hour (1-12)
- `HH12` – Hour (1-12)
- `HH24` – Hour (0-23)
- `MI` – Minutes (0-59)
- `MM` – Month (1-12)
- `MON` – Abbreviated name of month
- `MONTH` – Name of Month
- `PM` – Meridian indicator (after midday)
- `PM_DOT` – Meridian indicator (after midday)
- `RR` – 20th century dates in the 21st century. 2 digits in the `50-99` range are assumed starting from the year 2000, and `0-49` is assumed from 1900.
- `RRRR` – 20th century dates in the 21st century. 4 digits
- `SS` – Seconds
- `SYYYY` – Signed 4-digit year; MariaDB only supports positive years
- `Y` – 1-digit year
- `YY` – 2-digit year
- `YYY` – 3-digit year
- `YYYY` – 4 digit year

> **Note:**
>
> If no datetime is given, the current datetime is used. For example, if `'MM-DD HH-MM-SS'` is given, the current year is used. (This is Oracle behavior.)

Unsupported Options

- `BC`, `D`, `DL`, `DS`, `E`, `EE`, `FM`, `FX`, `RM`, `SSSSS`, `TS`, `TZD`, `TZH`, `TZR`, `X`, and `SY BC` are not supported by MariaDB datetime.
- Most other formats do not make sense in a MariaDB context, as we return `datetime` with fractions, not as a string.
- `D` (day-of-week) is not supported as it is not clear how it would map to MariaDB. This element depends on the NLS territory of the session.
- `RR` only works with 2-digit years. (In Oracle, `RR` may also work with 4-digit years in some context, but the rules are not clear.)

Extensions and Differences Compared to Oracle

- MariaDB supports `FF` (fractional seconds). If `FF[#]` is used, `TO_DATE` returns a `datetime` with `#` of subseconds. If `FF` is not used, a `datetime` is returned. A warning (but no error) is issued if the string contains more digits than specified with `F(#)`.
- Names can be shortened to their unique prefixes. For example, both `January` and `Ja` work fine.
- No error is issued if the datetime string is shorter than `format_string` and the next unused character is not a number. This is useful to get a `datetime` from a mixed set of strings in `datetime` format. By contrast, Oracle gives an error if the `datetime` string is too short.
- MariaDB supports short locales as language names.
- `NLS_DATE_FORMAT` can use double-quote (`"`) and single-quote (`'`) for quoting.

- `NLS_DATE_FORMAT` must be a constant string. This is to ensure that the server knows which locale to use when executing the function.

Examples

Convert a textual date and time to `DATE` format:

```
SELECT TO_DATE('February 5, 2026, 20:56','%Y-%m-%e')
+-----------------------------------------------+
| TO_DATE('February 5, 2026, 20:56','%Y-%m-%e') |
+-----------------------------------------------+
| 2026-02-05                                    |
+-----------------------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

TO_DAYS

Syntax

```
TO_DAYS(date)
```

Description

Given a date `date`, returns the number of days since the start of the current calendar (`0000-00-00`).

The function is not designed for use with dates before the advent of the Gregorian calendar in October 1582. Results are not reliable since it doesn't account for the lost days when the calendar changed from the Julian calendar.

This is the converse of the FROM_DAYS() function.

Examples

```
SELECT TO_DAYS('2007-10-07');
+-----------------------+
| TO_DAYS('2007-10-07') |
+-----------------------+
|                733321 |
+-----------------------+

SELECT TO_DAYS('0000-01-01');
+-----------------------+
| TO_DAYS('0000-01-01') |
+-----------------------+
|                     1 |
+-----------------------+

SELECT TO_DAYS(950501);
+-----------------+
| TO_DAYS(950501) |
+-----------------+
|          728779 |
+-----------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

TO_SECONDS

Syntax

```
TO_SECONDS(expr)
```

Description

Returns the number of seconds from year 0 till `expr`, or NULL if `expr` is not a valid date or datetime.

Examples

```
SELECT TO_SECONDS('2013-06-13');
+--------------------------+
| TO_SECONDS('2013-06-13') |
+--------------------------+
|              63538300800 |
+--------------------------+

SELECT TO_SECONDS('2013-06-13 21:45:13');
+-----------------------------------+
| TO_SECONDS('2013-06-13 21:45:13') |
+-----------------------------------+
|                       63538379113 |
+-----------------------------------+

SELECT TO_SECONDS(NOW());
+-------------------+
| TO_SECONDS(NOW()) |
+-------------------+
|       63543530875 |
+-------------------+

SELECT TO_SECONDS(20130513);
+----------------------+
| TO_SECONDS(20130513) |
+----------------------+
|          63535622400 |
+----------------------+
1 row in set (0.00 sec)

SELECT TO_SECONDS(130513);
+--------------------+
| TO_SECONDS(130513) |
+--------------------+
|        63535622400 |
+--------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

TRUNC

> **Note:**
>
> Introduced in MariaDB 12.2.

Syntax

```
TRUNC(date[,fmt])
```

Description

Returns a DATETIME truncated according to `fmt`.

Supported formats:

Truncate to day: `DD`, `DDD`, `J`
Truncate to month: `MM`, `MON`, `MONTH`, `RM`
Truncate to year: `SYEAR`, `SYYYY`, `Y`, `YEAR`, `YY`, `YYY`, `YYYY`

Examples

```
SELECT TRUNC('2025-09-24 12:43','DD');
+--------------------------------+
| TRUNC('2025-09-24 12:43','DD') |
+--------------------------------+
| 2025-09-24 00:00:00            |
+--------------------------------+

SELECT TRUNC('2025-09-24 12:43','MM');
+--------------------------------+
| TRUNC('2025-09-24 12:43','MM') |
+--------------------------------+
| 2025-09-01 00:00:00            |
+--------------------------------+

SELECT TRUNC('2025-09-24 12:43','YY');
+--------------------------------+
| TRUNC('2025-09-24 12:43','YY') |
+--------------------------------+
| 2025-01-01 00:00:00            |
+--------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

UNIX_TIMESTAMP

Syntax

```
UNIX_TIMESTAMP()
UNIX_TIMESTAMP(date)
```

Description

If called with no argument, returns a Unix timestamp (seconds since `1970-01-01 00:00:00` UTC) as an unsigned integer. If `UNIX_TIMESTAMP()` is called with a date argument, it returns the value of the argument as seconds since `1970-01-01 00:00:00` UTC. date may be a DATE string, a DATETIME string, a TIMESTAMP, or a number in the format `YYMMDD` or `YYYYMMDD`. The server interprets date as a value in the current time zone and converts it to an internal value in UTC. Clients can set their time zone as described in time zones.

The inverse function of `UNIX_TIMESTAMP()` is FROM_UNIXTIME()

`UNIX_TIMESTAMP()` supports microseconds.

> **CURRENT**
>
> Timestamps in MariaDB have a maximum value of `4294967295`, equivalent to `2106-02-07 06:28:15`. This is due to the underlying 32-bit limitation. Using the function on a timestamp beyond this will result in `NULL` being returned. Use DATETIME as a storage type if you require dates beyond this.
>
> **< 11.5**

> Timestamps in MariaDB have a maximum value of `2147483647`, equivalent to `2038-01-19 05:14:07`. This is due to the underlying 32-bit limitation. Using the function on a timestamp beyond this will result in `NULL` being returned. Use DATETIME as a storage type if you require dates beyond this.

Error Handling

Returns `NULL` for wrong arguments to `UNIX_TIMESTAMP()`.

Examples

```
SELECT UNIX_TIMESTAMP();
+------------------+
| UNIX_TIMESTAMP() |
+------------------+
|       1269711082 |
+------------------+

SELECT UNIX_TIMESTAMP('2007-11-30 10:30:19');
+---------------------------------------+
| UNIX_TIMESTAMP('2007-11-30 10:30:19') |
+---------------------------------------+
|                     1196436619.000000 |
+---------------------------------------+

SELECT UNIX_TIMESTAMP("2007-11-30 10:30:19.123456");
+-----------------------------------------------+
| unix_timestamp("2007-11-30 10:30:19.123456") |
+-----------------------------------------------+
|                            1196411419.123456 |
+-----------------------------------------------+

SELECT FROM_UNIXTIME(UNIX_TIMESTAMP('2007-11-30 10:30:19'));
+-------------------------------------------------------+
| FROM_UNIXTIME(UNIX_TIMESTAMP('2007-11-30 10:30:19')) |
+-------------------------------------------------------+
| 2007-11-30 10:30:19.000000                            |
+-------------------------------------------------------+

SELECT FROM_UNIXTIME(FLOOR(UNIX_TIMESTAMP('2007-11-30 10:30:19')));
+-------------------------------------------------------------+
| FROM_UNIXTIME(FLOOR(UNIX_TIMESTAMP('2007-11-30 10:30:19'))) |
+-------------------------------------------------------------+
| 2007-11-30 10:30:19                                         |
+-------------------------------------------------------------+
```

See Also

- FROM_UNIXTIME()

This page is licensed: GPLv2, originally from fill_help_tables.sql

UTC_DATE

Syntax

```
UTC_DATE, UTC_DATE()
```

Description

Returns the current UTC date as a value in `YYYY-MM-DD` or `YYYYMMDD` format, depending on whether the function is used in a string or numeric context.

Examples

```
SELECT UTC_DATE(), UTC_DATE() + 0;
+------------+----------------+
| UTC_DATE() | UTC_DATE() + 0 |
+------------+----------------+
| 2010-03-27 |       20100327 |
+------------+----------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

UTC_TIME

Syntax

```
UTC_TIME
UTC_TIME([precision])
```

Description

Returns the current UTC time as a value in `HH:MM:SS` or `HHMMSS.uuuuuu` format, depending on whether the function is used in a string or numeric context.

The optional *precision* determines the microsecond precision. See Microseconds in MariaDB.

Examples

```
SELECT UTC_TIME(), UTC_TIME() + 0;
+------------+----------------+
| UTC_TIME() | UTC_TIME() + 0 |
+------------+----------------+
| 17:32:34   |  173234.000000 |
+------------+----------------+
```

With precision:

```
SELECT UTC_TIME(5);
+----------------+
| UTC_TIME(5)    |
+----------------+
| 07:52:50.78369 |
+----------------+
```

See Also

- Microseconds in MariaDB

This page is licensed: GPLv2, originally from fill_help_tables.sql

UTC_TIMESTAMP

Syntax

```
UTC_TIMESTAMP
UTC_TIMESTAMP([precision])
```

Description

Returns the current UTC date and time as a value in `YYYY-MM-DD HH:MM:SS` or `YYYYMMDDHHMMSS.uuuuuu` format, depending on whether the function is used in a string or numeric context.

The optional *precision* determines the microsecond precision. See Microseconds in MariaDB.

Examples

```
SELECT UTC_TIMESTAMP(), UTC_TIMESTAMP() + 0;
+---------------------+----------------------+
| UTC_TIMESTAMP()     | UTC_TIMESTAMP() + 0   |
+---------------------+----------------------+
| 2010-03-27 17:33:16 | 20100327173316.000000 |
+---------------------+----------------------+
```

With precision:

```
SELECT UTC_TIMESTAMP(4);
+--------------------------+
| UTC_TIMESTAMP(4)         |
+--------------------------+
| 2018-07-10 07:51:09.1019 |
+--------------------------+
```

See Also

- Time Zones
- Microseconds in MariaDB

This page is licensed: GPLv2, originally from fill_help_tables.sql

WEEK

Syntax

```
WEEK(date[,mode])
```

Description

This function returns the week number for `date`. The two-argument form of `WEEK()` allows you to specify whether the week starts on Sunday or Monday and whether the return value should be in the range from 0 to 53 or from 1 to 53. If the `mode` argument is omitted, the value of the default_week_format system variable is used.

Modes

Mode	1st day of week	Range	Week 1 is the 1st week with
0	Sunday	0-53	a Sunday in this year
1	Monday	0-53	more than 3 days this year
2	Sunday	1-53	a Sunday in this year
3	Monday	1-53	more than 3 days this year
4	Sunday	0-53	more than 3 days this year
5	Monday	0-53	a Monday in this year
6	Sunday	1-53	more than 3 days this year
7	Monday	1-53	a Monday in this year

With the mode value of 3, which means ‘more than 3 days this year’, weeks are numbered according to ISO 8601:1988.

Examples

```
SELECT WEEK('2008-02-20');
+--------------------+
| WEEK('2008-02-20') |
+--------------------+
|                  7 |
+--------------------+

SELECT WEEK('2008-02-20',0);
+----------------------+
| WEEK('2008-02-20',0) |
+----------------------+
|                    7 |
+----------------------+

SELECT WEEK('2008-02-20',1);
+----------------------+
| WEEK('2008-02-20',1) |
+----------------------+
|                    8 |
+----------------------+

SELECT WEEK('2008-12-31',0);
+----------------------+
| WEEK('2008-12-31',0) |
+----------------------+
|                   52 |
+----------------------+

SELECT WEEK('2008-12-31',1);
+----------------------+
| WEEK('2008-12-31',1) |
+----------------------+
|                   53 |
+----------------------+

 SELECT WEEK('2019-12-30',3);
+----------------------+
| WEEK('2019-12-30',3) |
+----------------------+
|                    1 |
+----------------------+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
SELECT d, WEEK(d,0), WEEK(d,1) from t1;
+---------------------+-----------+-----------+
| d                   | WEEK(d,0) | WEEK(d,1) |
+---------------------+-----------+-----------+
| 2007-01-30 21:31:07 |         4 |         5 |
| 1983-10-15 06:42:51 |        41 |        41 |
| 2011-04-21 12:34:56 |        16 |        16 |
| 2011-10-30 06:31:41 |        44 |        43 |
| 2011-01-30 14:03:25 |         5 |         4 |

+---------------------+-----------+-----------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

WEEKDAY

Syntax

```
WEEKDAY(date)
```

Description

Returns the weekday index for `date` (`0` = Monday, `1` = Tuesday, … `6` = Sunday).

This contrasts with DAYOFWEEK() which follows the ODBC standard (`1` = Sunday, `2` = Monday, …, `7` = Saturday).

Examples

```
SELECT WEEKDAY('2008-02-03 22:23:00');
+--------------------------------+
| WEEKDAY('2008-02-03 22:23:00') |
+--------------------------------+
|                              6 |
+--------------------------------+

SELECT WEEKDAY('2007-11-06');
+-----------------------+
| WEEKDAY('2007-11-06') |
+-----------------------+
|                     1 |
+-----------------------+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
SELECT d FROM t1 where WEEKDAY(d) = 6;
+---------------------+
| d                   |
+---------------------+
| 2011-10-30 06:31:41 |
| 2011-01-30 14:03:25 |
+---------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

WEEKOFYEAR

Syntax

```
WEEKOFYEAR(date)
```

Description

Returns the calendar week of the date as a number in the range from 1 sqto 53. `WEEKOFYEAR()` is a compatibility function that is equivalent to WEEK(date,3).

Examples

```
SELECT WEEKOFYEAR('2008-02-20');
+--------------------------+
| WEEKOFYEAR('2008-02-20') |
+--------------------------+
|                        8 |
+--------------------------+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
SELECT * FROM t1;
+---------------------+
| d                   |
+---------------------+
| 2007-01-30 21:31:07 |
| 1983-10-15 06:42:51 |
| 2011-04-21 12:34:56 |
| 2011-10-30 06:31:41 |
| 2011-01-30 14:03:25 |
| 2004-10-07 11:19:34 |
+---------------------+
```

```
SELECT d, WEEKOFYEAR(d), WEEK(d,3) from t1;
+---------------------+---------------+-----------+
| d                   | WEEKOFYEAR(d) | WEEK(d,3) |
+---------------------+---------------+-----------+
| 2007-01-30 21:31:07 |             5 |         5 |
| 1983-10-15 06:42:51 |            41 |        41 |
| 2011-04-21 12:34:56 |            16 |        16 |
| 2011-10-30 06:31:41 |            43 |        43 |
| 2011-01-30 14:03:25 |             4 |         4 |
| 2004-10-07 11:19:34 |            41 |        41 |
+---------------------+---------------+-----------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

YEAR

Syntax

```
YEAR(date)
```

Description

Returns the year for the given date, in the range 1000 to 9999, or 0 for the “zero” date.

`SQL_TSI_YEAR` is a synonym for `YEAR`:

Examples

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
SELECT * FROM t1;
+---------------------+
| d                   |
+---------------------+
| 2007-01-30 21:31:07 |
| 1983-10-15 06:42:51 |
| 2011-04-21 12:34:56 |
| 2011-10-30 06:31:41 |
| 2011-01-30 14:03:25 |
| 2004-10-07 11:19:34 |
+---------------------+

SELECT * FROM t1 WHERE YEAR(d) = 2011;
+---------------------+
| d                   |
+---------------------+
| 2011-04-21 12:34:56 |
| 2011-10-30 06:31:41 |
| 2011-01-30 14:03:25 |
+---------------------+
```

```
SELECT YEAR('1987-01-01');
+--------------------+
| YEAR('1987-01-01') |
+--------------------+
|               1987 |
+--------------------+
```

YEAR Format

```
CREATE TABLE year_format_example (
  description VARCHAR(30),
  example YEAR
);
```

```
INSERT INTO year_format_example VALUES
  ('4-digit numeric year', 1966),
  ('2-digit numeric year', 66),
  ('4-digit string year', '1966'),
  ('2-digit string year', '66');
```

The resulting output would look like this:

```
SELECT * FROM year_format_example;

+----------------------+---------+
| description          | example |
+----------------------+---------+
| 4-digit numeric year |    1966 |
| 2-digit numeric year |    2066 |
| 4-digit string year  |    1966 |
| 2-digit string year  |    2066 |
+----------------------+---------+
```

YEAR Range

```
CREATE TABLE year_range_example (
  description VARCHAR(30),
  example YEAR
);
```

```
INSERT INTO year_range_example VALUES
  ('minimum', 1901),
  ('maximum', 2155),
  ('below minimum', 1900),
  ('above maximum', 2156);
```

If `SQL_MODE` is strict (the default), the example above generates the following error and no values are inserted:

```
ERROR 1264 (22003): Out of range value for column 'example' at row 3
```

If `SQL_MODE` is not strict, the example above generates a warning and (possibly modified) values are inserted:

```
Warning (sql 1264): Out of range value for column 'example' at row 3
Warning (sql 1264): Out of range value for column 'example' at row 4
The resulting data would look like this:
```

```
SELECT * FROM year_range_example;

+---------------+---------+
| description   | example |
+---------------+---------+
| minimum       |    1901 |
| maximum       |    2155 |
| below minimum |    0000 |
| above maximum |    0000 |
+---------------+---------+
```

Zero YEAR

```
CREATE TABLE year_zero_example (
  description VARCHAR(30),
  example YEAR
);
```

```
INSERT INTO year_zero_example VALUES
  ('4-digit numeric zero', 0000),
  ('3-digit numeric zero', 000),
  ('2-digit numeric zero', 00),
  ('1-digit numeric zero', 0),
  ('4-digit string zero', '0000'),
  ('3-digit string zero', '000'),
  ('2-digit string zero', '00'),
  ('1-digit string zero', '0');
```

The resulting data would look like this:

```
SELECT * FROM year_zero_example;

+----------------------+---------+
| description          | example |
+----------------------+---------+
| 4-digit numeric zero |    0000 |
| 3-digit numeric zero |    0000 |
| 2-digit numeric zero |    0000 |
| 1-digit numeric zero |    0000 |
| 4-digit string zero  |    0000 |
| 3-digit string zero  |    2000 |
| 2-digit string zero  |    2000 |
| 1-digit string zero  |    2000 |
+----------------------+---------+
```

- YEAR data type

This page is licensed: GPLv2, originally from fill_help_tables.sql

YEARWEEK

Syntax

```
YEARWEEK(date), YEARWEEK(date,mode)
```

Description

Returns year and week for a date. The mode argument works exactly like the mode argument to WEEK(). The year in the result may be different from the year in the date argument for the first and the last week of the year.

Examples

```
SELECT YEARWEEK('1987-01-01');
+-----------------------+
| YEARWEEK('1987-01-01') |
+-----------------------+
|                 198652 |
+-----------------------+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
SELECT * FROM t1;
+---------------------+
| d                   |
+---------------------+
| 2007-01-30 21:31:07 |
| 1983-10-15 06:42:51 |
| 2011-04-21 12:34:56 |
| 2011-10-30 06:31:41 |
| 2011-01-30 14:03:25 |
| 2004-10-07 11:19:34 |
+---------------------+
6 rows in set (0.02 sec)
```

```
SELECT YEARWEEK(d) FROM t1 WHERE YEAR(d) = 2011;
+-------------+
| YEARWEEK(d) |
+-------------+
|      201116 |
|      201144 |
|      201105 |
+-------------+
3 rows in set (0.03 sec)
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

Numeric Functions

See ABS.

Calculate absolute value. This function returns the non-negative value of a number, removing any negative sign.

See ACOS.

Calculate arc cosine. This function returns the angle in radians whose cosine is the given number.

See ASIN.

Calculate arc cosine. This function returns the angle in radians whose cosine is the given number.

See ATAN.

Calculate arc tangent. This function returns the angle in radians whose tangent is the given number.

See ATAN2.

Calculate arc tangent of two variables. This function returns the angle in radians between the positive x-axis and the point (X, Y).

See CEIL.

Synonym for CEILING(). Rounds a number up to the nearest integer.

See CEILING.

Round up to the nearest integer. This function returns the smallest integer value that is greater than or equal to the argument.

See CONV.

Convert numbers between bases. This function transforms a number from one numeric base system to another.

See COS.

Calculate cosine. This function returns the cosine of an angle given in radians.

See COT.

Calculate cotangent. This function returns the cotangent of an angle given in radians.

See CRC32.

Compute cyclic redundancy check. This function returns a 32-bit unsigned integer representing the CRC32 checksum of a string.

See CRC32C.

Compute CRC32C checksum. This function calculates a cyclic redundancy check value using the Castagnoli polynomial.

See DEGREES.

Convert radians to degrees. This function transforms an angle measured in radians to its equivalent in degrees.

See DIV.

Perform integer division. This operator divides one number by another and returns the integer result, discarding any remainder.

See EXP.

Calculate exponential value. This function returns the value of e (the base of natural logarithms) raised to the power of the argument.

See FLOOR.

Round down to the nearest integer. This function returns the largest integer value that is less than or equal to the argument.

See LN.

Calculate natural logarithm. This function returns the logarithm of a number to the base e.

See LOG.

Calculate logarithm. This function returns the natural logarithm of a number, or the logarithm to a specified base if two arguments are provided.

See LOG10.

Calculate base-10 logarithm. This function returns the logarithm of a number to the base 10.

See LOG2.

Calculate base-2 logarithm. This function returns the logarithm of a number to the base 2.

See MOD.

Calculate modulo. This function returns the remainder of a number divided by another number.

See OCT.

Convert to octal. This function returns the octal string representation of a numeric argument.

See PI.

Return the value of pi. This function returns the mathematical constant π (approximately 3.141593).

See POW.

Synonym for POWER(). Returns the value of a number raised to the power of another number.

See POWER.

Calculate power. This function returns the value of a number raised to the specified exponent.

See RADIANS.

Convert degrees to radians. This function transforms an angle measured in degrees to its equivalent in radians.

See RAND.

Generate a random number. This function returns a random floating-point value between 0 and 1.

See ROUND.

Round a number. This function rounds a number to a specified number of decimal places.

See SIGN.

Return the sign of a number. This function returns -1, 0, or 1 depending on whether the argument is negative, zero, or positive.

See SIN.

Calculate sine. This function returns the sine of an angle given in radians.

See SQRT.

Calculate square root. This function returns the non-negative square root of a number.

See TAN.

Calculate tangent. This function returns the tangent of an angle given in radians.

See TO_NUMBER.

Convert a string to a number. This Oracle-compatible function parses a string using a specified format and returns a numeric value.

See TRUNCATE.

Truncate a number. This function truncates a number to a specified number of decimal places.

This page is licensed: CC BY-SA / Gnu FDL

ABS

Syntax

```
ABS(X)
```

Description

Returns the absolute (non-negative) value of `X`. If `X` is not a number, it is converted to a numeric type.

Examples

```
SELECT ABS(42);
+---------+
| ABS(42) |
+---------+
|      42 |
+---------+

SELECT ABS(-42);
+----------+
| ABS(-42) |
+----------+
|       42 |
+----------+

SELECT ABS(DATE '1994-01-01');
+------------------------+
| ABS(DATE '1994-01-01') |
+------------------------+
|               19940101 |
+------------------------+
```

See Also

- SIGN()

This page is licensed: GPLv2, originally from fill_help_tables.sql

ACOS

Syntax

```
ACOS(X)
```

Description

Returns the arc cosine of `X`, that is, the value whose cosine is `X`. Returns `NULL` if `X` is not in the range `-1` to `1`.

Examples

```
SELECT ACOS(1);
+---------+
| ACOS(1) |
+---------+
|       0 |
+---------+

SELECT ACOS(1.0001);
+--------------+
| ACOS(1.0001) |
+--------------+
|         NULL |
+--------------+

SELECT ACOS(0);
+-----------------+
| ACOS(0)         |
+-----------------+
| 1.5707963267949 |
+-----------------+

SELECT ACOS(0.234);
+------------------+
| ACOS(0.234)      |
+------------------+
| 1.33460644244679 |
+------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ASIN

Syntax

```
ASIN(X)
```

Description

Returns the arc sine of X, that is, the value whose sine is X. Returns `NULL` if X is not in the range -1 to 1.

Examples

```
SELECT ASIN(0.2);
+--------------------+
| ASIN(0.2)          |
+--------------------+
| 0.2013579207903308 |
+--------------------+

SELECT ASIN('foo');
+-------------+
| ASIN('foo') |
+-------------+
|           0 |
+-------------+

SHOW WARNINGS;
+---------+------+----------------------------------------+
| Level   | Code | Message                                |
+---------+------+----------------------------------------+
| Warning | 1292 | Truncated incorrect DOUBLE value: 'foo' |
+---------+------+----------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ATAN

Syntax

```
ATAN(X)
```

Description

Returns the arc tangent of X, that is, the value whose tangent is X.

Examples

```
SELECT ATAN(2);
+-------------------+
| ATAN(2)           |
+-------------------+
| 1.1071487177940904 |
+-------------------+

SELECT ATAN(-2);
+--------------------+
| ATAN(-2)           |
+--------------------+
| -1.1071487177940904 |
+--------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ATAN2

Syntax

```
ATAN(Y,X), ATAN2(Y,X)
```

Description

Returns the arc tangent of the two variables X and Y. It is similar to calculating the arc tangent of Y / X, except that the signs of both arguments are used to determine the quadrant of the result.

Examples

```
SELECT ATAN(-2,2);
+--------------------+
| ATAN(-2,2)         |
+--------------------+
| -0.7853981633974483 |
+--------------------+

SELECT ATAN2(PI(),0);
+-------------------+
| ATAN2(PI(),0)     |
+-------------------+
| 1.5707963267948966 |
+-------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

CEIL

Syntax

```
CEIL(X)
```

Description

`CEIL()` is a synonym for CEILING().

This page is licensed: GPLv2, originally from fill_help_tables.sql

CEILING

Syntax

```
CEILING(X)
```

Description

Returns the smallest integer value not less than X.

Examples

```
SELECT CEILING(1.23);
+---------------+
| CEILING(1.23) |
+---------------+
|             2 |
+---------------+

SELECT CEILING(-1.23);
+----------------+
| CEILING(-1.23) |
+----------------+
|             -1 |
+----------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

CONV

Syntax

```
CONV(N,from_base,to_base)
```

Description

Converts numbers between different number bases. Returns a string representation of the number `N`, converted from base `from_base` to base `to_base`.

Returns `NULL` if any argument is `NULL`, or if the second or third argument are not in the allowed range.

> **CURRENT**
>
> The argument `N` is interpreted as an integer, but may be specified as an integer or a string. The minimum base is 2 and the maximum base is 62. If `to_base` is a negative number, `N` is regarded as a signed number. Otherwise, `N` is treated as unsigned. `CONV()` works with 64-bit precision.

< 11.4

The argument `N` is interpreted as an integer, but may be specified as an integer or a string. The minimum base is 2 and the maximum base is 36. If `to_base` is a negative number, `N` is regarded as a signed number. Otherwise, `N` is treated as unsigned. `CONV()` works with 64-bit precision.

Some shortcuts for this function are also available: BIN(), OCT(), HEX(), UNHEX(). Also, MariaDB allows binary literal values and hexadecimal literal values.

Examples

```
SELECT CONV('a',16,2);
+----------------+
| CONV('a',16,2) |
+----------------+
| 1010           |
+----------------+

SELECT CONV('6E',18,8);
+-----------------+
| CONV('6E',18,8) |
+-----------------+
| 172             |
+-----------------+

SELECT CONV(-17,10,-18);
+------------------+
| CONV(-17,10,-18) |
+------------------+
| -H               |
+------------------+

SELECT CONV(12+'10'+'10'+0xa,10,10);
+-------------------------------+
| CONV(12+'10'+'10'+0xa,10,10) |
+-------------------------------+
| 42                            |
+-------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

COS

Syntax

```
COS(X)
```

Description

Returns the cosine of X, where X is given in radians.

Examples

```
SELECT COS(PI());
+-----------+
| COS(PI()) |
+-----------+
|        -1 |
+-----------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

COT

Syntax

```
COT(X)
```

Description

Returns the cotangent of X.

Examples

```
SELECT COT(42);
+--------------------+
| COT(42)            |
+--------------------+
| 0.4364167060752729 |
+--------------------+

SELECT COT(12);
+---------------------+
| COT(12)             |
+---------------------+
| -1.5726734063976893 |
+---------------------+

SELECT COT(0);
ERROR 1690 (22003): DOUBLE value is out of range in 'cot(0)'
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

CRC32

Syntax

CURRENT

```
CRC32([par,]expr)
```

< 10.8

```
CRC32(expr)
```

Description

Computes a cyclic redundancy check (CRC) value and returns a 32-bit unsigned value. The result is `NULL` if the argument is `NULL`. The argument is expected to be a string and (if possible) is treated as one if it is not.

CURRENT

Uses the alternate Castagnoli polynomia.

Often, CRC is computed in pieces. To facilitate this, there's an optional parameter: CRC32('MariaDB')=CRC32(CRC32('Maria'),'DB').

< 10.8

Uses the ISO 3309 polynomial that used by zlib and many others.

Examples

CURRENT

```
SELECT CRC32(CRC32('Maria'),'DB');
+----------------------------+
| CRC32(CRC32('Maria'),'DB') |
+----------------------------+
|                 4227209140 |
+----------------------------+
```

< 10.8

```
SELECT CRC32('MariaDB');
+------------------+
| CRC32('MariaDB') |
+------------------+
|       4227209140 |
+------------------+

SELECT CRC32('mariadb');
+------------------+
| CRC32('mariadb') |
+------------------+
|       2594253378 |
+------------------+
```

See Also

- CRC32C()

This page is licensed: GPLv2, originally from fill_help_tables.sql

CRC32C

> **Note:**
>
> `CRC32C` is available from MariaDB 10.8.

`CRC32C` is used to compute a cyclic redundancy check (CRC) value using the Castagnoli polynomial.

Syntax

```
CRC32C([par,]expr)
```

Description

MariaDB has always included a native unary function CRC32() that computes the CRC-32 of a string using the ISO 3309 polynomial that used by zlib and many others.

InnoDB and MyRocks use a different polynomial, which was implemented in SSE4.2 instructions that were introduced in the Intel Nehalem microarchitecture. This is commonly called CRC-32C (Castagnoli).

The CRC32C function uses the Castagnoli polynomial.

This allows `SELECT…INTO DUMPFILE` to be used for the creation of files with valid checksums, such as a logically empty InnoDB redo log file `ib_logfile0` corresponding to a particular log sequence number.

The optional parameter allows the checksum to be computed in pieces: CRC32C('MariaDB')=CRC32C(CRC32C('Maria'),'DB').

Examples

```
SELECT CRC32C('MariaDB');
+-------------------+
| CRC32C('MariaDB') |
+-------------------+
|         809606978 |
+-------------------+

SELECT CRC32C(CRC32C('Maria'),'DB');
+------------------------------+
| CRC32C(CRC32C('Maria'),'DB') |
+------------------------------+
|                    809606978 |
+------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

DEGREES

Syntax

```
DEGREES(X)
```

Description

Returns the argument `X`, converted from radians to degrees.

This is the converse of the RADIANS() function.

Examples

```
SELECT DEGREES(PI());
+---------------+
| DEGREES(PI()) |
+---------------+
|           180 |
+---------------+

SELECT DEGREES(PI() / 2);
+-------------------+
| DEGREES(PI() / 2) |
+-------------------+
|                90 |
+-------------------+

SELECT DEGREES(45);
+-----------------+
| DEGREES(45)     |
+-----------------+
| 2578.3100780887 |
+-----------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

DIV

Syntax

```
DIV
```

Description

Integer division. Similar to FLOOR(), but is safe with BIGINT values. Incorrect results may occur for non-integer operands that exceed the `BIGINT` range.

If the `ERROR_ON_DIVISION_BY_ZERO` SQL_MODE is used, a division by zero produces an error. Otherwise, it returns `NULL`.

The remainder of a division can be obtained using the MOD operator.

Examples

```
SELECT 300 DIV 7;
+-----------+
| 300 DIV 7 |
+-----------+
|        42 |
+-----------+

SELECT 300 DIV 0;
+-----------+
| 300 DIV 0 |
+-----------+

This page is licensed: GPLv2, originally from fill_help_tables.sql

EXP

Syntax

```
EXP(X)
```

Description

Returns the value of e (the base of natural logarithms) raised to the power of X. The inverse of this function is LOG() (using a single argument only) or LN().

If `X` is `NULL`, this function returns `NULL`.

Examples

```
SELECT EXP(2);
+------------------+
| EXP(2)           |
+------------------+
| 7.38905609893065 |
+------------------+

SELECT EXP(-2);
+--------------------+
| EXP(-2)            |
+--------------------+
| 0.1353352832366127 |
+--------------------+

SELECT EXP(0);
+--------+
| EXP(0) |
+--------+
|      1 |
+--------+

SELECT EXP(NULL);
+-----------+
| EXP(NULL) |
+-----------+
|      NULL |
+-----------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

FLOOR

Syntax

```
FLOOR(X)
```

Description

Returns the largest integer value not greater than X.

Examples

```
SELECT FLOOR(1.23);
+-------------+
| FLOOR(1.23) |
+-------------+
|           1 |
+-------------+

SELECT FLOOR(-1.23);
+--------------+
| FLOOR(-1.23) |
+--------------+
|           -2 |
+--------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

LN

Syntax

```
LN(X)
```

Description

Returns the natural logarithm of X; that is, the base-e logarithm of X. If X is less than or equal to 0, or `NULL`, then `NULL` is returned.

The inverse of this function is EXP().

Examples

```
SELECT LN(2);
+-------------------+
| LN(2)             |
+-------------------+
| 0.693147180559945 |
+-------------------+

SELECT LN(-2);
+--------+
| LN(-2) |
+--------+
|   NULL |
+--------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

LOG

Syntax

```
LOG(X), LOG(B,X)
```

Description

If called with one parameter, this function returns the natural logarithm of X. If X is less than or equal to 0, then `NULL` is returned.

If called with two parameters, it returns the logarithm of X to the base B. If B is <= 1 or X <= 0, the function returns `NULL`.

If any argument is `NULL`, the function returns `NULL`.

The inverse of this function (when called with a single argument) is the EXP() function.

Examples

LOG(X):

```
SELECT LOG(2);
+-------------------+
| LOG(2)            |
+-------------------+
| 0.693147180559945 |
+-------------------+

SELECT LOG(-2);
+---------+
| LOG(-2) |
+---------+
|    NULL |
+---------+
```

LOG(B,X)

```
SELECT LOG(2,16);
+-----------+
| LOG(2,16) |
+-----------+
|         4 |
+-----------+

SELECT LOG(3,27);
+-----------+
| LOG(3,27) |
+-----------+
|         3 |
+-----------+

SELECT LOG(3,1);
+----------+
| LOG(3,1) |
+----------+
|        0 |
+----------+

SELECT LOG(3,0);
+----------+
| LOG(3,0) |
+----------+
|     NULL |
+----------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

LOG10

Syntax

```
LOG10(X)
```

Description

Returns the base-10 logarithm of X.

Examples

```
SELECT LOG10(2);
+-------------------+
| LOG10(2)          |
+-------------------+
| 0.301029995663981 |
+-------------------+

SELECT LOG10(100);
+------------+
| LOG10(100) |
+------------+
|          2 |
+------------+

SELECT LOG10(-100);
+-------------+
| LOG10(-100) |
+-------------+
|        NULL |
+-------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

LOG2

Syntax

```
LOG2(X)
```

Description

Returns the base-2 logarithm of X.

Examples

```
SELECT LOG2(4398046511104);
+---------------------+
| LOG2(4398046511104) |
+---------------------+
|                  42 |
+---------------------+

SELECT LOG2(65536);
+-------------+
| LOG2(65536) |
+-------------+
|          16 |
+-------------+

SELECT LOG2(-100);
+------------+
| LOG2(-100) |
+------------+
|       NULL |
+------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

MOD

Syntax

```
MOD(N,M), N % M, N MOD M
```

Description

Modulo operation. Returns the remainder of N divided by M. See also Modulo Operator.

If the `ERROR_ON_DIVISION_BY_ZERO` SQL_MODE is used, any number modulus zero produces an error. Otherwise, it returns `NULL`.

The integer part of a division can be obtained using DIV.

Examples

```
SELECT 1042 % 50;
+-----------+
| 1042 % 50 |
+-----------+
|        42 |
+-----------+

SELECT MOD(234, 10);
+--------------+
| MOD(234, 10) |
+--------------+
|            4 |
+--------------+

SELECT 253 % 7;
+---------+
| 253 % 7 |
+---------+
|       1 |
+---------+

SELECT MOD(29,9);
+-----------+
| MOD(29,9) |
+-----------+
|         2 |
+-----------+

SELECT 29 MOD 9;
+----------+
| 29 MOD 9 |
+----------+
|        2 |
+----------+
```

See Also

- Operator Precedence

This page is licensed: GPLv2, originally from fill_help_tables.sql

OCT

Syntax

```
OCT(N)
```

Description

Returns a string representation of the octal value of N, where N is a longlong (BIGINT) number. This is equivalent to CONV(N,10,8). Returns `NULL` if N is `NULL`.

Examples

```
SELECT OCT(34);
+---------+
| OCT(34) |
+---------+
| 42      |
+---------+

SELECT OCT(12);
+---------+
| OCT(12) |
+---------+
| 14      |
+---------+
```

See Also

- CONV()
- BIN()
- HEX()

This page is licensed: GPLv2, originally from fill_help_tables.sql

PI

Syntax

```
PI()
```

Description

Returns the value of π (pi). The default number of decimal places displayed is six, but MariaDB uses the full double-precision value internally.

Examples

```
SELECT PI();
+----------+
| PI()     |
+----------+
| 3.141593 |
+----------+

SELECT PI()+0.0000000000000000000000;
+-------------------------------+
| PI()+0.0000000000000000000000 |
+-------------------------------+
|      3.1415926535897931159980 |
+-------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

POW

Syntax

```
POW(X,Y)
```

Description

Returns the value of X raised to the power of Y.

`POWER()` is a synonym.

Examples

```
SELECT POW(2,3);
+----------+
| POW(2,3) |
+----------+
|        8 |
+----------+

SELECT POW(2,-2);
+-----------+
| POW(2,-2) |
+-----------+
|      0.25 |
+-----------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

POWER

Syntax

```
POWER(X,Y)
```

Description

This is a synonym for POW(), which returns the value of X raised to the power of Y.

This page is licensed: GPLv2, originally from fill_help_tables.sql

RADIANS

Syntax

```
RADIANS(X)
```

Description

Returns the argument *X*, converted from degrees to radians. Note that π radians equals 180 degrees.

This is the converse of the DEGREES() function.

Examples

```
SELECT RADIANS(45);
+------------------+
| RADIANS(45)      |
+------------------+
| 0.785398163397448 |
+------------------+

SELECT RADIANS(90);
+-----------------+
| RADIANS(90)     |
+-----------------+
| 1.5707963267949 |
+-----------------+

SELECT RADIANS(PI());
+--------------------+
| RADIANS(PI())      |
+--------------------+
| 0.0548311355616075 |
+--------------------+

SELECT RADIANS(180);
+------------------+
| RADIANS(180)     |
+------------------+
| 3.14159265358979 |
+------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

RAND

Syntax

```
RAND(), RAND(N)
```

Description

Returns a random DOUBLE precision floating point value v in the range 0 <= v < 1.0. If a constant integer argument N is specified, it is used as the seed value, which produces a repeatable sequence of column values. In the example below, note that the sequences of values produced by `RAND(3)` is the same both places where it occurs.

In a `WHERE` clause, `RAND()` is evaluated each time the `WHERE` is executed.

Statements using the `RAND()` function are not safe for statement-based replication.

Practical uses

The expression to get a random integer from a given range is the following:

```
FLOOR(min_value + RAND() * (max_value - min_value +1))
```

`RAND()` is often used to read random rows from a table, as follows:

```
SELECT * FROM my_table ORDER BY RAND() LIMIT 10;
```

Warning:

Note, however, that this technique should never be used **on a large table** as it will be extremely slow. MariaDB will read all rows in the table, generate a random value for each of them, order them, and finally will apply the `LIMIT` clause.

Examples

```
CREATE TABLE t (i INT);

INSERT INTO t VALUES(1),(2),(3);

SELECT i, RAND() FROM t;
+------+------------------+
| i    | RAND()           |
+------+------------------+
|    1 | 0.255651095188829 |
|    2 | 0.833920199269355 |
|    3 |  0.40264774151393 |
+------+------------------+

SELECT i, RAND(3) FROM t;
+------+------------------+
| i    | RAND(3)          |
+------+------------------+
|    1 |  0.90576975597606 |
|    2 | 0.373079058130345 |
|    3 | 0.148086053457191 |
+------+------------------+

SELECT i, RAND() FROM t;
+------+------------------+
| i    | RAND()           |
+------+------------------+
|    1 | 0.511478140495232 |
|    2 | 0.349447508668012 |
|    3 | 0.212803152588013 |
+------+------------------+
```

Using the same seed, the same sequence will be returned:

```
SELECT i, RAND(3) FROM t;
+------+------------------+
| i    | RAND(3)          |
+------+------------------+
|    1 |  0.90576975597606 |
|    2 | 0.373079058130345 |
|    3 | 0.148086053457191 |
+------+------------------+
```

Generating a random number from 5 to 15:

```
SELECT FLOOR(5 + (RAND() * 11));
```

- Techniques for Efficiently Finding a Random Row
- rand_seed1 and rand_seed2 system variables

This page is licensed: GPLv2, originally from fill_help_tables.sql

ROUND

Syntax

```
ROUND(X), ROUND(X,D)
```

Description

Rounds the argument `X` to `D` decimal places. `D` defaults to `0` if not specified. `D` can be negative to cause `D` digits left of the decimal point of the value `X` to become zero.

The rounding algorithm depends on the data type of `X`:

- For floating-point types (FLOAT, DOUBLE) the C libraries rounding function is used, so the behavior *may* differ between operating systems.
- For fixed-point types (DECIMAL, DEC/NUMBER/FIXED) the “round half up” rule is used, meaning that e.g. a value ending in exactly .5 is always rounded up.

Examples

```
SELECT ROUND(-1.23);
+--------------+
| ROUND(-1.23) |
+--------------+
|           -1 |
+--------------+

SELECT ROUND(-1.58);
+--------------+
| ROUND(-1.58) |
+--------------+
|           -2 |
+--------------+

SELECT ROUND(1.58);
+-------------+
| ROUND(1.58) |
+-------------+
|           2 |
+-------------+

SELECT ROUND(1.298, 1);
+-----------------+
| ROUND(1.298, 1) |
+-----------------+
|             1.3 |
+-----------------+

SELECT ROUND(1.298, 0);
+-----------------+
| ROUND(1.298, 0) |
+-----------------+
|               1 |
+-----------------+

SELECT ROUND(23.298, -1);
+------------------+
| ROUND(23.298, -1) |
+------------------+
|                20 |
+------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

SIGN

Syntax

```
SIGN(X)
```

Description

Returns the sign of the argument as -1, 0, or 1, depending on whether X is negative, zero, or positive.

Examples

```
SELECT SIGN(-32);
+-----------+
| SIGN(-32) |
+-----------+
|        -1 |
+-----------+

SELECT SIGN(0);
+---------+
| SIGN(0) |
+---------+
|       0 |
+---------+

SELECT SIGN(234);
+-----------+
| SIGN(234) |
+-----------+
|         1 |
+-----------+
```

See Also

- ABS()

This page is licensed: GPLv2, originally from fill_help_tables.sql

SIN

Syntax

```
SIN(X)
```

Description

Returns the sine of X, where X is given in radians.

Examples

```
SELECT SIN(1.5707963267948966);
+-------------------------+
| SIN(1.5707963267948966) |
+-------------------------+
|                       1 |
+-------------------------+

SELECT SIN(PI());
+----------------------+
| SIN(PI())            |
+----------------------+
| 1.22460635382238e-16 |
+----------------------+

+------------------+
| ROUND(SIN(PI())) |
+------------------+
|                0 |
+------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

SQRT

Syntax

```
SQRT(X)
```

Description

Returns the square root of X. If X is negative, `NULL` is returned.

Examples

```
SELECT SQRT(4);
+---------+
| SQRT(4) |
+---------+
|       2 |
+---------+

SELECT SQRT(20);
+------------------+
| SQRT(20)         |
+------------------+
| 4.47213595499958 |
+------------------+

SELECT SQRT(-16);
+-----------+
| SQRT(-16) |
+-----------+
|      NULL |
+-----------+

SELECT SQRT(1764);
+------------+
| SQRT(1764) |
+------------+
|         42 |
+------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

TAN

Syntax

```
TAN(X)
```

Description

Returns the tangent of X, where X is given in radians.

Examples

```
SELECT TAN(0.7853981633974483);
+-------------------------+
| TAN(0.7853981633974483) |
+-------------------------+
|      0.9999999999999999 |
+-------------------------+

SELECT TAN(PI());
+----------------------+
| TAN(PI())            |
+----------------------+
| -1.22460635382238e-16 |
+----------------------+

SELECT TAN(PI()+1);
+-----------------+
| TAN(PI()+1)     |
+-----------------+
| 1.5574077246549 |
+-----------------+

SELECT TAN(RADIANS(PI()));
+--------------------+
| TAN(RADIANS(PI())) |
+--------------------+
| 0.0548861508080033 |
+--------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

TO_NUMBER

Note:

`TO_NUMBER` is available from MariaDB 12.2.

`TO_NUMBER` converts an expression to the NUMERIC data type.

Syntax

```
TO_NUMBER(number_or_string_subject)
TO_NUMBER(string_subject,string_format)
```

Description

The function returns the `DOUBLE` data type for all signatures and input data types.

The format parser understands the following components:

- Digits: 0, 9
- Hex digits: X
- Group separators: comma (`,`) and G
- Decimal delimiters: period (`.`) and D
- Approximate number signature: EEEE
- Currency/numeric flags: $ and B
- Currency signatures: C, L, U
- Sign signatures: S, MI, PR
- Special format signatures: V, TM, TM9, TME
- Format flag: FM

The function was introduced for Oracle compatibility, but does not include the following features:

- The `ON CONVERSION ERROR` clause
- The third parameter (nlsparam)
- Internationalized components: G, D, C, L, U

These features are planned to be implemented via MDEV-36978.

Examples

```
SELECT TO_NUMBER('100.00');
+---------------------+
| TO_NUMBER('100.00') |
+---------------------+
|                 100 |
+---------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

TRUNCATE

This page documents the `TRUNCATE` function. See TRUNCATE TABLE for the DDL statement.

Syntax

```
TRUNCATE(X,D)
```

Description

Returns the number X, truncated to D decimal places. If D is 0, the result has no decimal point or fractional part. D can be negative to cause D digits left of the decimal point of the value X to become zero.

Examples

```
SELECT TRUNCATE(1.223,1);
+------------------+
| TRUNCATE(1.223,1) |
+------------------+
|               1.2 |
+------------------+

SELECT TRUNCATE(1.999,1);
+------------------+
| TRUNCATE(1.999,1) |
+------------------+
|               1.9 |
+------------------+

SELECT TRUNCATE(1.999,0);
+------------------+
| TRUNCATE(1.999,0) |
+------------------+
|                 1 |
+------------------+

SELECT TRUNCATE(-1.999,1);
+-------------------+
| TRUNCATE(-1.999,1) |
+-------------------+
|               -1.9 |
+-------------------+

SELECT TRUNCATE(122,-2);
+-----------------+
| TRUNCATE(122,-2) |
+-----------------+
|              100 |
+-----------------+

SELECT TRUNCATE(10.28*100,0);
+----------------------+
| TRUNCATE(10.28*100,0) |
+----------------------+
|                 1028 |
+----------------------+
```

See Also

- TRUNCATE TABLE

This page is licensed: GPLv2, originally from fill_help_tables.sql

XXH3

> **Note:**
>
> `XXH3` was added in MariaDB 13.1.

Syntax

```
XXH3(expr)
```

Description

`XXH3` returns a fast, non-cryptographic xxHash of a text value as a 64-bit number (`BIGINT UNSIGNED`). It's useful for checksums, change detection, and grouping or bucketing rows. For a 32-bit result, use XXH32().

The argument must be a text value: a string, `BLOB` / `TEXT`, `JSON`, `ENUM`, or `SET`. Numbers, dates, and other non-text values are rejected with an error; CAST() them to a string first.

Hashing `NULL` returns `NULL`. Hashing an empty string returns `0`.

The result depends on the collation, not on the raw bytes. Values that count as equal under the collation hash to the same number (for example, `'abc'` and `'ABC'` under a case-insensitive collation). The same text in a different character set or collation gives a different number.

> **Warning:**
>
> When comparing a column to a value, keep both sides in the same collation. If the hashed column and the value use different collations, they won't match, so a hash-based index or lookup can quietly find nothing. Hash the binary form with `CAST(... AS BINARY)` (or the `BINARY` operator) when you want a byte-exact hash that ignores collation.

Predicting the partition for KEY partitioning

The same XXH3 algorithm is available as a KEY partitioning algorithm (`PARTITION BY KEY ALGORITHM=XXH3`). For a table partitioned on a single column, the partition a value lands in is `MOD(XXH3(value), number_of_partitions)` — handy for knowing where a row will go, or for partition pruning. The collation rule above still applies: the value must use the column's collation to predict correctly.

This shortcut holds only for a plain, single-column `KEY`. It doesn't apply to LINEAR KEY (unless the number of partitions is a power of two), to multi-column keys, or to `NULL` values (the server places those itself).

> **Note:**
>
> `XXH32` is the 32-bit variant. The `XXH64()` and `XXH128()` functions are not part of this release.

Examples

```
SELECT XXH3('abc');
+---------------------+
| XXH3('abc')         |
+---------------------+
| 5167207402487786768 |
+---------------------+
```

The result depends on the session collation, so a bare literal reproduces only under the same collation (the result above is for the default `utf8mb4_uca1400_ai_ci`). For a byte-exact hash that doesn't depend on collation, hash the binary form:

```
SELECT XXH3(CAST('abc' AS BINARY));
+-----------------------------+
| XXH3(CAST('abc' AS BINARY)) |
+-----------------------------+
|         8696274497037089104 |
+-----------------------------+
```

`NULL` and the empty string:

```
SELECT XXH3(NULL), XXH3('');
+------------+----------+
| XXH3(NULL) | XXH3('') |
+------------+----------+
|       NULL |        0 |
+------------+----------+
```

Equal values under a case-insensitive collation hash to the same number:

```
SELECT XXH3(_utf8mb4'ABC' COLLATE utf8mb4_general_ci)
     = XXH3(_utf8mb4'abc' COLLATE utf8mb4_general_ci) AS equal_ci;
+----------+
| equal_ci |
+----------+
|        1 |
+----------+
```

A non-text argument is rejected:

```
SELECT XXH3(11223344);
ERROR 4079 (HY000): Illegal parameter data type int for operation 'XXH3'
```

XXH32

Note:

`XXH32` was added in MariaDB 13.1.

Syntax

```
XXH32(expr)
```

Description

`XXH32` returns a fast, non-cryptographic xxHash of a text value as a 32-bit number (`INT UNSIGNED`). It's useful for checksums, change detection, and grouping or bucketing rows. For a 64-bit result, use XXH3().

The argument must be a text value: a string, `BLOB` / `TEXT`, `JSON`, `ENUM`, or `SET`. Numbers, dates, and other non-text values are rejected with an error; CAST() them to a string first.

Hashing `NULL` returns `NULL`. Hashing an empty string returns `0`.

The result depends on the collation, not on the raw bytes. Values that count as equal under the collation hash to the same number (for example, `'abc'` and `'ABC'` under a case-insensitive collation). The same text in a different character set or collation gives a different number.

Warning:

When comparing a column to a value, keep both sides in the same collation. If the hashed column and the value use different collations, they won't match, so a hash-based index or lookup can quietly find nothing. Hash the binary form with `CAST(... AS BINARY)` (or the `BINARY` operator) when you want a byte-exact hash that ignores collation.

Predicting the partition for KEY partitioning

The same XXH32 algorithm is available as a KEY partitioning algorithm (`PARTITION BY KEY ALGORITHM=XXH32`). For a table partitioned on a single column, the partition a value lands in is `MOD(XXH32(value), number_of_partitions)` — handy for knowing where a row will go, or for partition pruning. The collation rule above still applies: the value must use the column's collation to predict correctly.

This shortcut holds only for a plain, single-column `KEY`. It doesn't apply to LINEAR KEY (unless the number of partitions is a power of two), to multi-column keys, or to `NULL` values (the server places those itself).

> **Note:**
>
> `XXH3` is the 64-bit variant. The `XXH64()` and `XXH128()` functions are not part of this release.

Examples

```
SELECT XXH32('abc');
+--------------+
| XXH32('abc') |
+--------------+
|    560666315 |
+--------------+
```

The result depends on the session collation, so a bare literal reproduces only under the same collation (the result above is for the default `utf8mb4_uca1400_ai_ci`). For a byte-exact hash that doesn't depend on collation, hash the binary form:

```
SELECT XXH32(CAST('abc' AS BINARY));
+------------------------------+
| XXH32(CAST('abc' AS BINARY)) |
+------------------------------+
|                    852579327 |
+------------------------------+
```

`NULL` and the empty string:

```
SELECT XXH32(NULL), XXH32('');
+-------------+-----------+
| XXH32(NULL) | XXH32('') |
+-------------+-----------+
|        NULL |         0 |
+-------------+-----------+
```

Equal values under a case-insensitive collation hash to the same number:

```
SELECT XXH32(_utf8mb4'ABC' COLLATE utf8mb4_general_ci)
     = XXH32(_utf8mb4'abc' COLLATE utf8mb4_general_ci) AS equal_ci;
+----------+
| equal_ci |
+----------+
|        1 |
+----------+
```

A non-text argument is rejected:

```
SELECT XXH32(11223344);
ERROR 4079 (HY000): Illegal parameter data type int for operation 'XXH32'
```

Pseudo Columns

See _rowid.

Access the unique row identifier. This pseudo column often aliases the primary key, allowing direct row access even if the primary key column name is unknown.

This page is licensed: CC BY-SA / Gnu FDL

_rowid

Syntax

```
_rowid
```

Description

The `_rowid` pseudo column is mapped to the primary key in the related table. This can be used as a replacement of the `rowid` pseudo column in other databases. Another usage is to simplify sql queries as one doesn't have to know the name of the primary key.

Examples

```
CREATE TABLE t1 (a INT PRIMARY KEY, b VARCHAR(80));
INSERT INTO t1 VALUES (1,"one"),(2,"two");
SELECT * FROM t1 WHERE _rowid=1;
```

```
+---+------+
| a | b    |
+---+------+
| 1 | one  |
+---+------+
```

```
UPDATE t1 SET b="three" WHERE _rowid=2;
SELECT * FROM t1 WHERE _rowid>=1 AND _rowid<=10;
```

```
+---+-------+
| a | b     |
+---+-------+
| 1 | one   |
| 2 | three |
+---+-------+
```

Secondary Functions

See Bit Functions and Operators.

Perform bitwise logic and manipulation. This section covers operators like AND, OR, XOR, and functions for shifting bits or counting set bits in binary data.

See Encryption, Hashing and Compression Functions.

Learn about encryption, hashing, and compression functions. This section details SQL functions for securing data, generating hashes, and compressing/decompressing information within your database.

See Information Functions.

Retrieve system and session metadata. This section details functions to access database names, user details, version info, and query statistics like row counts.

See Miscellaneous Functions.

Explore specialized utilities. This category includes functions for benchmarking, managing UUIDs, converting IP addresses, and handling binary data formats.

This page is licensed: CC BY-SA / Gnu FDL

Bit Functions and Operators

See BIT_COUNT.

Count the set bits. This function returns the number of bits that are set to 1 in the binary representation of a number.

See ~.

Invert all bits. This unary operator flips every bit in the operand, changing 1s to 0s and 0s to 1s.

See |.

Perform bitwise OR. This operator compares bits and returns 1 if at least one of the corresponding bits is 1.

See ^.

Perform bitwise exclusive OR. This operator returns 1 only if the corresponding bits of the operands are different.

See &.

Perform bitwise AND. This operator compares bits of two operands and returns 1 only if both corresponding bits are 1.

See Parentheses.

Control operator precedence. Parentheses are used to group expressions and enforce the order of evaluation in complex operations.

See <<.

Shift bits to the left. This operator shifts the binary representation of a number to the left by a specified number of positions, filling with zeros.

See >>.

Shift bits to the right. This operator shifts the binary representation of a number to the right by a specified number of positions.

See TRUE FALSE.

Boolean literal for 1 = TRUE or 0 = FALSE, respectively.

This page is licensed: CC BY-SA / Gnu FDL

BIT_COUNT

Syntax

```
BIT_COUNT(N)
```

Description

Returns the number of bits that are set in the argument N.

Examples

```
SELECT BIT_COUNT(29), BIT_COUNT(b'101010');
+---------------+----------------------+
| BIT_COUNT(29) | BIT_COUNT(b'101010') |
+---------------+----------------------+
|             4 |                    3 |
+---------------+----------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

~

Syntax

```
~
```

Description

Bitwise NOT. Converts the value to 4 bytes binary and inverts all bits.

Examples

```
SELECT 3 & ~1;
+--------+
| 3 & ~1 |
+--------+
|      2 |
+--------+

SELECT 5 & ~1;
+--------+
| 5 & ~1 |
+--------+
|      4 |
+--------+
```

See Also

- Operator Precedence

This page is licensed: CC BY-SA / Gnu FDL

|

Syntax

```
|
```

Description

Bitwise OR. Converts the values to binary and compares bits. If either of the corresponding bits has a value of 1, the resulting bit is also 1.

See also bitwise AND.

Examples

```
SELECT 2|1;
+-----+
| 2|1 |
+-----+
|   3 |
+-----+

SELECT 29 | 15;
+---------+
| 29 | 15 |
+---------+
|      31 |
+---------+
```

See Also

- Operator Precedence

This page is licensed: GPLv2, originally from fill_help_tables.sql

^

Syntax

```
^
```

Description

Bitwise XOR. Converts the values to binary and compares bits. If one (and only one) of the corresponding bits is 1 is the resulting bit also 1.

Examples

```
SELECT 1 ^ 1;
+-------+
| 1 ^ 1 |
+-------+
|     0 |
+-------+

SELECT 1 ^ 0;
+-------+
| 1 ^ 0 |
+-------+
|     1 |
+-------+

SELECT 11 ^ 3;
+--------+
| 11 ^ 3 |
+--------+
|      8 |
+--------+
```

See Also

- Operator Precedence

This page is licensed: GPLv2, originally from fill_help_tables.sql

&

Syntax

```
&
```

Description

Bitwise AND. Converts the values to binary and compares bits. Only if both the corresponding bits are 1 is the resulting bit also 1.

See also bitwise OR.

Examples

```
SELECT 2&1;
+-----+
| 2&1 |
+-----+
|   0 |
+-----+

SELECT 3&1;
+-----+
| 3&1 |
+-----+
|   1 |
+-----+

SELECT 29 & 15;
+---------+
| 29 & 15 |
+---------+
|      13 |
+---------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

Parentheses

Parentheses are sometimes called precedence operators - this means that they can be used to change the other operator's precedence in an expression. The expressions that are written between parentheses are computed before the expressions that are written outside. Parentheses must always contain an expression (that is, they cannot be empty), and can be nested.

For example, the following expressions could return different results:

- `NOT a OR b`
- `NOT (a OR b)`

In the first case, `NOT` applies to `a`, so if `a` is `FALSE` or `b` is `TRUE`, the expression returns `TRUE`. In the second case, `NOT` applies to the result of `a OR b`, so if at least one of `a` or `b` is `TRUE`, the expression is `TRUE`.

When the precedence of operators is not intuitive, you can use parentheses to make it immediately clear for whoever reads the statement.

The precedence of the `NOT` operator can also be affected by the `HIGH_NOT_PRECEDENCE` SQL_MODE flag.

Other uses

Parentheses must always be used to enclose subqueries.

Parentheses can also be used in a JOIN statement between multiple tables to determine which tables must be joined first.

Also, parentheses are used to enclose the list of parameters to be passed to built-in functions, user-defined functions and stored routines. However, when no parameter is passed to a stored procedure, parentheses are optional. For builtin functions and user-defined functions, spaces are not allowed between the function name and the open parenthesis, unless the `IGNORE_SPACE` SQL_MODE is set. For stored routines (and for functions if `IGNORE_SPACE` is set) spaces are allowed before the open parenthesis, including tab characters and new line characters.

Syntax errors

If there are more open parentheses than closed parentheses, the error usually looks like this:

```
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that
corresponds to your MariaDB server version for the right syntax to use near '' a
t line 1
```

Note the empty string.

If there are more closed parentheses than open parentheses, the error usually looks like this:

```
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that
corresponds to your MariaDB server version for the right syntax to use near ')'
at line 1
```

Note the quoted closed parenthesis.

This page is licensed: CC BY-SA / Gnu FDL

<<

Syntax

```
value1 << value2
```

Description

Converts a longlong (BIGINT) number (*value1*) to binary and shifts *value2* units to the left.

Examples

```
SELECT 1 << 2;
+--------+
| 1 << 2 |
+--------+
|      4 |
+--------+
```

- Operator Precedence

This page is licensed: GPLv2, originally from fill_help_tables.sql

TRUE FALSE

Description

The constants `TRUE` and `FALSE` evaluate to 1 and 0, respectively. The constant names can be written in any lettercase.

Examples

```
SELECT TRUE, true, FALSE, false;
+------+------+-------+-------+
| TRUE | TRUE | FALSE | FALSE |
+------+------+-------+-------+
|    1 |    1 |     0 |     0 |
+------+------+-------+-------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

Encryption, Hashing and Compression Functions

AES_DECRYPT

Syntax

CURRENT

```
AES_ENCRYPT(crypt_str, key_str, [, iv [, mode]])
```

< 11.2

```
AES_DECRYPT(crypt_str,key_str)
```

Description

This function allows decryption of data using the official AES (Advanced Encryption Standard) algorithm. For more information, see the description of AES_ENCRYPT().

CURRENT

The function supports an initialization vector, and control of the block encryption mode. The default mode is specified by the block_encryption_mode system variable, which can be changed when calling the function with a mode. *mode* is aes-{128,192,256}-{ecb,cbc,ctr} for example: “AES-128-cbc”.

For modes that require it, the initialization_vector *iv* should be 16 bytes (it can be longer, but the extra bytes are ignored). A shorter *iv*, where one is required, results in the function returning `NULL`. Calling RANDOM_BYTES(16) will generate a random series of bytes that can be used for the *iv*.

Examples

```
SELECT HEX(AES_ENCRYPT('foo', 'bar', '0123456789abcdef', 'aes-128-ctr')) AS x;
+--------+
| x      |
+--------+
| C57C4B |
+--------+

SELECT AES_DECRYPT(x'C57C4B', 'bar', '0123456789abcdef', 'aes-128-ctr');
+-----------------------------------------------------------------+
| AES_DECRYPT(x'C57C4B', 'bar', '0123456789abcdef', 'aes-128-ctr') |
+-----------------------------------------------------------------+
| foo                                                             |
+-----------------------------------------------------------------+
```

< 11.2

The function does **not** support an initialization vector.

This page is licensed: GPLv2, originally from fill_help_tables.sql

AES_ENCRYPT

Syntax

CURRENT

```
AES_ENCRYPT(str, key, [, iv [, mode]])
```

< 11.2

```
AES_ENCRYPT(str,key_str)
```

Description

`AES_ENCRYPT()` and AES_DECRYPT() allow encryption and decryption of data using the official AES (Advanced Encryption Standard) algorithm, previously known as "Rijndael." Encoding with a 128-bit key length is used (from MariaDB 11.2.0, this is the default, and can be changed). 128 bits is much faster and is secure enough for most purposes.

`AES_ENCRYPT()` encrypts a string *`str`* using the key *`key_str`*, and returns a binary string.

`AES_DECRYPT()` decrypts the encrypted string and returns the original string.

The input arguments may be any length. If either argument is `NULL`, the result of this function is also `NULL`.

Because AES is a block-level algorithm, padding is used to encode uneven length strings and so the result string length may be calculated using this formula:

```
16 x (trunc(string_length / 16) + 1)
```

If `AES_DECRYPT()` detects invalid data or incorrect padding, it returns `NULL`. However, it is possible for `AES_DECRYPT()` to return a non-`NULL` value (possibly garbage) if the input data or the key is invalid.

MariaDB starting with 11.2

CURRENT

The function supports an initialization vector, and control of the block encryption mode. The default mode is specified by the block_encryption_mode system variable, which can be changed when calling the function with a mode. *mode* is aes-{128,192,256}-{ecb,cbc,ctr} for example: "AES-128-cbc".
`AES_ENCRYPT(str, key)` can no longer be used in persistent virtual columns (and the like).

TAB 2

The function does **not** support an initialization vector.

Examples

CURRENT

```
SELECT HEX(AES_ENCRYPT('foo', 'bar', '0123456789abcdef', 'aes-256-cbc')) AS x;
+----------------------------------+
| x                                |
+----------------------------------+
| 42A3EB91E6DFC40A900D278F99E0726E |
+----------------------------------+
```

< 11.2

```
INSERT INTO t VALUES (AES_ENCRYPT('text',SHA2('password',512)));
```

See Also

- RANDOM_BYTES() is a function for generating good encryption keys for `AES_ENCRYPT`.
- KDF() is a key derivation function which is useful if an authentication validation against the value is required without data being able to be decrypted.

This page is licensed: GPLv2, originally from fill_help_tables.sql

COMPRESS

Syntax

```
COMPRESS(string_to_compress)
```

Description

Compresses a string and returns the result as a binary string. This function requires MariaDB to have been compiled with a compression library such as zlib. Otherwise, the return value is always `NULL`. The compressed string can be uncompressed with UNCOMPRESS().

The have_compress server system variable indicates whether a compression library is present.

Examples

```
SELECT LENGTH(COMPRESS(REPEAT('a',1000)));
+-----------------------------------+
| LENGTH(COMPRESS(REPEAT('a',1000))) |
+-----------------------------------+
|                                21 |
+-----------------------------------+

SELECT LENGTH(COMPRESS(''));
+----------------------+
| LENGTH(COMPRESS('')) |
+----------------------+
|                    0 |
+----------------------+

SELECT LENGTH(COMPRESS('a'));
+-----------------------+
| LENGTH(COMPRESS('a')) |
+-----------------------+
|                    13 |
+-----------------------+

SELECT LENGTH(COMPRESS(REPEAT('a',16)));
+---------------------------------+
| LENGTH(COMPRESS(REPEAT('a',16))) |
+---------------------------------+
|                              15 |
+---------------------------------+
```

See Also

- Automatic compression of columns

This page is licensed: GPLv2, originally from fill_help_tables.sql

DECODE

Syntax

```
DECODE(crypt_str,pass_str)
```

In Oracle mode:

```
DECODE(expr, search_expr, result_expr [, search_expr2, result_expr2 ...] [default_expr])
```

In all modes:

```
DECODE_ORACLE(expr, search_expr, result_expr [, search_expr2, result_expr2 ...] [default_expr])
```

Description

In the default mode, `DECODE` decrypts the encrypted string *`crypt_str`* using *`pass_str`* as the password. *crypt_str* should be a string returned from ENCODE(). The resulting string will be the original string only if *`pass_str`* is the same.

In Oracle mode, `DECODE` compares *`expr`* to the search expressions, in order. If it finds a match, the corresponding result expression is returned. If no matches are found, the default expression is returned, or `NULL` if no default is provided.

`NULL` values are treated as equivalent.

`DECODE_ORACLE` is a synonym for the Oracle-mode version of the function, and is available in all modes.

Examples

```
SELECT DECODE_ORACLE(2+1,3*1,'found1',3*2,'found2','default');
+-------------------------------------------------------+
| DECODE_ORACLE(2+1,3*1,'found1',3*2,'found2','default') |
+-------------------------------------------------------+
| found1                                                |
+-------------------------------------------------------+

SELECT DECODE_ORACLE(2+4,3*1,'found1',3*2,'found2','default');
+-------------------------------------------------------+
| DECODE_ORACLE(2+4,3*1,'found1',3*2,'found2','default') |
+-------------------------------------------------------+
| found2                                                |
+-------------------------------------------------------+

SELECT DECODE_ORACLE(2+2,3*1,'found1',3*2,'found2','default');
+-------------------------------------------------------+
| DECODE_ORACLE(2+2,3*1,'found1',3*2,'found2','default') |
+-------------------------------------------------------+
| default                                               |
+-------------------------------------------------------+
```

`NULL` values are treated as equivalent:

```
SELECT DECODE_ORACLE(NULL,NULL,'Nulls are equivalent','Nulls are not equivalent');
+-----------------------------------------------------------------------------+
| DECODE_ORACLE(NULL,NULL,'Nulls are equivalent','Nulls are not equivalent') |
+-----------------------------------------------------------------------------+
| Nulls are equivalent                                                        |
+-----------------------------------------------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

DES_DECRYPT

> **Warning:**
>
> `DES_DECRYPT` was **removed in MariaDB 13.0**, together with the `--des-key-file` option and the `FLUSH DES_KEY_FILE` statement. It was deprecated in earlier releases. Use AES_DECRYPT() instead. The description below applies to MariaDB releases before 13.0.

Syntax

```
DES_DECRYPT(crypt_str[,key_str])
```

Description

Decrypts a string encrypted with DES_ENCRYPT(). If an error occurs, this function returns `NULL`.

This function works only if MariaDB has been configured with TLS support.

If no `key_str` argument is given, `DES_DECRYPT()` examines the first byte of the encrypted string to determine the DES key number that was used to encrypt the original string, and then reads the key from the DES key file to decrypt the message. For this to work, the user must have the SUPER privilege. The key file can be specified with the `--des-key-file` server option.

If you pass this function a `key_str` argument, that string is used as the key for decrypting the message.

If the `crypt_str` argument does not appear to be an encrypted string, MariaDB returns the given `crypt_str`.

This page is licensed: GPLv2, originally from fill_help_tables.sql

DES_ENCRYPT

> **Warning:**
>
> `DES_ENCRYPT` was **removed in MariaDB 13.0**, together with the `--des-key-file` option and the `FLUSH DES_KEY_FILE` statement. It was deprecated in earlier releases. Use AES_ENCRYPT() instead. The description below applies to MariaDB releases before 13.0.

Syntax

```
DES_ENCRYPT(str[,{key_num|key_str}])
```

Description

Encrypts the string with the given key using the Triple-DES algorithm.

This function works only if MariaDB has been configured with TLS support.

The encryption key to use is chosen based on the second argument to `DES_ENCRYPT()`, if one was given. With no argument, the first key from the DES key file is used. With a *`key_num`* argument, the given key number (0-9) from the DES key file is used. With a *`key_str`* argument, the given key string is used to encrypt *`str`*.

The key file can be specified with the `--des-key-file` server option.

The return string is a binary string where the first character is `CHAR(128 | key_num)`. If an error occurs, `DES_ENCRYPT()` returns `NULL`.

The 128 is added to make it easier to recognize an encrypted key. If you use a string key, *`key_num`* is 127.

The string length for the result is given by this formula:

```
new_len = orig_len + (8 - (orig_len % 8)) + 1
```

Each line in the DES key file has the following format:

```
key_num des_key_str
```

Each *`key_num`* value must be a number in the range from 0 to 9. Lines in the file may be in any order. *`des_key_str`* is the string that is used to encrypt the message. There should be at least one space between the number and the key. The first key is the default key that is used if you do not specify any key argument to `DES_ENCRYPT()`.

You can tell MariaDB to read new key values from the key file with the `FLUSH DES_KEY_FILE` statement. This requires the RELOAD privilege.

One benefit of having a set of default keys is that it gives applications a way to check for the existence of encrypted column values, without giving the end user the right to decrypt those values.

Examples

```
SELECT customer_address FROM customer_table
   WHERE crypted_credit_card = DES_ENCRYPT('credit_card_number');
```

See Also

- DES_DECRYPT()

This page is licensed: GPLv2, originally from fill_help_tables.sql

ENCODE

Syntax

```
ENCODE(str,pass_str)
```

Description

> **Warning:**
>
> `ENCODE` is not considered cryptographically secure, and should not be used for password encryption.

Encrypt `str` using `pass_str` as the password. To decrypt the result, use DECODE().

The result is a binary string of the same length as `str`.

The strength of the encryption is based on how good the random generator is.

It is not recommended to rely on the encryption performed by the ENCODE function. Using a salt value (changed when a password is updated) will improve matters somewhat, but for storing passwords, consider a more cryptographically secure function, such as SHA2().

Examples

```
ENCODE('not so secret text', CONCAT('random_salt','password'))
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ENCRYPT

Syntax

```
ENCRYPT(str[,salt])
```

Description

Encrypts a string using the Unix crypt() system call, returning an encrypted binary string. The `salt` argument should be a string with at least two characters or the returned result will be NULL. If no salt argument is given, a random value of sufficient length is used.

It is not recommended to use ENCRYPT() with utf16, utf32 or ucs2 multi-byte character sets because the crypt() system call expects a string terminated with a zero byte.

Note that the underlying crypt() system call may have some limitations, such as ignoring all but the first eight characters.

If the have_crypt system variable is set to `NO` (because the crypt() system call is not available), the ENCRYPT function will always return NULL.

Examples

```
SELECT ENCRYPT('encrypt me');
+-----------------------+
| ENCRYPT('encrypt me') |
+-----------------------+
| 4I5BsEx0lqTDk         |
+-----------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

KDF

> **Note:**
>
> `KDF()` is a key derivation function available from MariaDB 11.3.0.

Syntax

```
KDF(key_str, salt [, {info | iterations} [, kdf_name [, width ]]])
```

Description

`KDF` is a key derivation function, similar to OpenSSL's EVP_KDF_derive(). The purpose of a KDF is to be slow, so if the calculated value is lost/stolen, the original `key_str` is not achievable easily with modern GPU. KDFs are therefore an ideal replacement for password hashes. KDFs can also pad out a password secret to the number of bits used in encryption algorithms.

For generating good encryption keys for AES_ENCRYPT a less expensive but cryptographically secure function like RANDOM_BYTES is recommended.

- `kdf_name` is "hkdf" or "pbkdf2_hmac" (default).
- Width (in bits) can be any number divisible by 8, by default it's taken from @@block_encryption_mode.
- Iterations must be positive, and is 1000 by default.

Note that OpenSSL 1.0 doesn't support HKDF, so in this case `NULL` is returned. This OpenSSL version is still used in SLES 12 and CentOS 7.

Examples

```
select hex(kdf('foo', 'bar', 'infa', 'hkdf'));
+---------------------------------------+
| hex(kdf('foo', 'bar', 'infa', 'hkdf')) |
+---------------------------------------+
| 612875F859CFB4EE0DFEFF9F2A18E836       |
+---------------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

MD5

Syntax

```
MD5(str)
```

Description

Calculates an MD5 128-bit checksum for the string.

The return value is a 32-hex digit string, and a nonbinary string in the connection character set and collation, determined by the values of the character_set_connection and collation_connection system variables.

`NULL` is returned if the argument was `NULL`.

> **Warning:**
>
> **Don't use this function as an encryption function.**
>
> MD5 can be used as a checksum to verify data integrity against unintentional corruption. Historically it was widely used as a cryptographic hash function; however it has been found to suffer from extensive vulnerabilities.
>
> See https://en.wikipedia.org/wiki/MD5 for details.

Examples

```
SELECT MD5('testing');
+----------------------------------+
| MD5('testing')                   |
+----------------------------------+
| ae2b1fca515949e5d54fb22b8ed95575 |
+----------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

OLD_PASSWORD

Syntax

```
OLD_PASSWORD(str)
```

Description

`OLD_PASSWORD()` was added to MySQL when the implementation of PASSWORD() was changed to improve security. `OLD_PASSWORD()` returns the value of the old (pre-MySQL 4.1) implementation of `PASSWORD()` as a string, and is intended to permit you to reset passwords for any pre-4.1 clients that need to connect to a more recent MySQL server version, or any version of MariaDB, without locking them out.

The return value is a nonbinary string in the connection character set and collation, determined by the values of the character_set_connection and collation_connection system variables.

The return value is 16 bytes in length, or `NULL` if the argument was `NULL`.

See Also

- PASSWORD()
- MySQL manual on password hashing

This page is licensed: GPLv2, originally from fill_help_tables.sql

PASSWORD

Syntax

```
PASSWORD(str)
```

Description

The `PASSWORD()` function is used for hashing passwords for use in authentication by the MariaDB server. It is not intended for use in other applications.

Calculates and returns a hashed password string from the plaintext password *str*. Returns an empty string if the argument is `NULL`.

The return value is a nonbinary string in the connection character set and collation, determined by the values of the character_set_connection and collation_connection system variables.

This is the function that is used for hashing MariaDB passwords for storage in the Password column of the user table (see privileges), usually used with the SET PASSWORD statement. It is not intended for use in other applications.

The function takes into account the authentication plugin where applicable (a CREATE USER or SET PASSWORD statement). For example, when used in conjunction with a user authenticated by the ed25519 plugin, the statement will create a longer hash:

```
CREATE USER edtest@localhost IDENTIFIED VIA ed25519 USING PASSWORD('secret');

CREATE USER edtest2@localhost IDENTIFIED BY 'secret';

SELECT CONCAT(user, '@', host, ' => ', JSON_DETAILED(priv)) FROM mysql.global_priv
  WHERE user LIKE 'edtest%'\G
*************************** 1. row ***************************
CONCAT(user, '@', host, ' => ', JSON_DETAILED(priv)): edtest@localhost => {
...
    "plugin": "ed25519",
    "authentication_string": "ZIgUREUg5PVgQ6LskhXmO+eZLS0nC8be6HPjYWR4YJY",
...
}
*************************** 2. row ***************************
CONCAT(user, '@', host, ' => ', JSON_DETAILED(priv)): edtest2@localhost => {
...
    "plugin": "mysql_native_password",
    "authentication_string": "*14E65567ABDB5135D0CFD9A70B3032C179A49EE7",
...
}
```

The behavior of this function is affected by the value of the old_passwords system variable. If this is set to `1` (`0` is default), MariaDB reverts to using the mysql_old_password authentication plugin by default for newly created users and passwords.

Examples

```
SELECT PASSWORD('notagoodpwd');
+-------------------------------------------+
| PASSWORD('notagoodpwd')                   |
+-------------------------------------------+
| *3A70EE9FC6594F88CE9E959CD51C5A1C002DC937 |
+-------------------------------------------+
```

```
SET PASSWORD FOR 'bob'@'%.loc.gov' = PASSWORD('newpass');
```

RANDOM_BYTES

> **Note:**
>
> `RANDOM_BYTES` is available from MariaDB 10.10.0.

The `RANDOM_BYTES` function generates a binary string of random bytes.

Syntax

```
RANDOM_BYTES(length)
```

Description

Given a *length* from 1 to 1024, generates a binary string of *length* consisting of random bytes generated by the SSL library's random number generator.

See the `RAND_bytes()` function documentation of your SSL library for information on the random number generator. In the case of OpenSSL, a cryptographically secure pseudo random generator (CSPRNG) is used.

Statements containing the RANDOM_BYTES function are unsafe for statement-based replication.

An error occurs if *length* is outside the range 1 to 1024.

This page is licensed: CC BY-SA / Gnu FDL

SHA1

Syntax

```
SHA1(str), SHA(str)
```

Description

Calculates an SHA-1 160-bit checksum for the string `str`, as described in RFC 3174 (Secure Hash Algorithm).

The value is returned as a string of 40 hex digits, or `NULL` if the argument was NULL. The return value is a nonbinary string in the connection character set and collation, determined by the values of the character_set_connection and collation_connection system variables.

Examples

```
SELECT SHA1('some boring text');
+------------------------------------------+
| SHA1('some boring text')                 |
+------------------------------------------+
| af969fc2085b1bb6d31e517d5c456def5cdd7093 |
+------------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

SHA2

Syntax

```
SHA2(str,hash_len)
```

Description

Given a string `str`, calculates an SHA-2 checksum, which is considered more cryptographically secure than its SHA-1 equivalent. The SHA-2 family includes SHA-224, SHA-256, SHA-384, and SHA-512, and the `hash_len` must correspond to one of these, i.e. 224, 256, 384 or 512. 0 is equivalent to 256.

The return value is a nonbinary string in the connection character set and collation, determined by the values of the character_set_connection and collation_connection system variables.

`NULL` is returned if the hash length is not valid, or the string `str` is `NULL`.

> **Warning:**
>
> `SHA2` only works if MariaDB is configured with TLS support.

Examples

```
SELECT SHA2('Maria',224);
+----------------------------------------------------------+
| SHA2('Maria',224)                                        |
+----------------------------------------------------------+
| 6cc67add32286412efcab9d0e1675a43a5c2ef3cec8879f81516ff83 |
+----------------------------------------------------------+

SELECT SHA2('Maria',256);
+------------------------------------------------------------------+
| SHA2('Maria',256)                                                |
+------------------------------------------------------------------+
| 9ff18ebe7449349f358e3af0b57cf7a032c1c6b2272cb2656ff85eb112232f16 |
+------------------------------------------------------------------+

SELECT SHA2('Maria',0);
+------------------------------------------------------------------+
| SHA2('Maria',0)                                                  |
+------------------------------------------------------------------+
| 9ff18ebe7449349f358e3af0b57cf7a032c1c6b2272cb2656ff85eb112232f16 |
+------------------------------------------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

UNCOMPRESS

Syntax

```
UNCOMPRESS(string_to_uncompress)
```

Description

Uncompresses a string compressed by the COMPRESS() function. If the argument is not a compressed value, the result is `NULL`. This function requires MariaDB to have been compiled with a compression library such as zlib. Otherwise, the return value is always `NULL`. The have_compress server system variable indicates whether a compression library is present.

Examples

```
SELECT UNCOMPRESS(COMPRESS('a string'));
+----------------------------------+
| UNCOMPRESS(COMPRESS('a string')) |
+----------------------------------+
| a string                         |
+----------------------------------+

SELECT UNCOMPRESS('a string');
+------------------------+
| UNCOMPRESS('a string') |
+------------------------+
| NULL                   |
+------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

UNCOMPRESSED_LENGTH

Syntax

```
UNCOMPRESSED_LENGTH(compressed_string)
```

Description

Returns the length that the compressed string had before being compressed with COMPRESS().

`UNCOMPRESSED_LENGTH()` returns `NULL` or an incorrect result if the string is not compressed.

Returns `MYSQL_TYPE_LONG`, or int(10), if the result fits within 32-bits.

Examples

```
SELECT UNCOMPRESSED_LENGTH(COMPRESS(REPEAT('a',30)));
+-----------------------------------------------+
| UNCOMPRESSED_LENGTH(COMPRESS(REPEAT('a',30))) |
+-----------------------------------------------+
|                                            30 |
+-----------------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

BENCHMARK

Syntax

```
BENCHMARK(count,expr)
```

Description

The BENCHMARK() function executes the expression `expr` repeatedly `count` times. It may be used to time how quickly MariaDB processes the expression. The result value is always 0. The intended use is from within the mariadb client, which reports query execution times.

Examples

```
SELECT BENCHMARK(1000000,ENCODE('hello','goodbye'));
+--------------------------------------------+
| BENCHMARK(1000000,ENCODE('hello','goodbye')) |
+--------------------------------------------+
|                                          0 |
+--------------------------------------------+
1 row in set (0.21 sec)
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

BINLOG_GTID_POS

Syntax

```
BINLOG_GTID_POS(binlog_filename,binlog_offset)
```

Description

The BINLOG_GTID_POS() function takes as input an old-style binary log position in the form of a file name and a file offset. It looks up the position in the current binlog, and returns a string representation of the corresponding GTID position. If the position is not found in the current binlog, NULL is returned.

Examples

```
SELECT BINLOG_GTID_POS("master-bin.000001", 600);
```

See Also

- SHOW BINLOG EVENTS - Show events and their positions in the binary log

This page is licensed: CC BY-SA / Gnu FDL

CHARSET

Syntax

```
CHARSET(str)
```

Description

Returns the character set of the string argument. If `str` is not a string, it is considered as a binary string (so the function returns 'binary'). This applies to `NULL`, too. The return value is a string in the utf8 character set.

Examples

```
SELECT CHARSET('abc');
+----------------+
| CHARSET('abc') |
+----------------+
| latin1         |
+----------------+

SELECT CHARSET(CONVERT('abc' USING utf8));
+-----------------------------------+
| CHARSET(CONVERT('abc' USING utf8)) |
+-----------------------------------+
| utf8                              |
+-----------------------------------+

SELECT CHARSET(USER());
+-----------------+
| CHARSET(USER()) |
+-----------------+
| utf8            |
+-----------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

COERCIBILITY

Syntax

```
COERCIBILITY(str)
```

Description

Returns the collation coercibility value of the string argument. Coercibility defines what will be converted to what in case of collation conflict, with an expression with higher coercibility being converted to the collation of an expression with lower coercibility.

Coercibility	Description	Example
0	Explicit	Value using a COLLATE clause
1	No collation	Concatenated strings using different collations
2	Implicit	A string data type column value, CAST to a string data type
3	System constant	DATABASE(), USER() return value
4	Coercible	Literal string
5	Numeric	Numeric and temporal values
6	Ignorable	NULL or derived from NULL

Examples

```
SELECT COERCIBILITY(_latin1 'abc' COLLATE latin1_swedish_ci);
+---------------------------------------------+
| COERCIBILITY(_latin1 'abc' COLLATE latin1_swedish_ci) |
+---------------------------------------------+
|                                           0 |
+---------------------------------------------+

CREATE TABLE t (a VARCHAR(30) COLLATE uca1400_swedish_ai_ci, b VARCHAR(30) COLLATE uca1400_german2_ai_ci)
CHARSET utf8mb4;
INSERT INTO t VALUES ('abc', 'def'); /* a 2 coercibility */
SELECT COERCIBILITY(CONCAT(a, b)) FROM t;
+----------------------------+
| COERCIBILITY(CONCAT(a, b)) |
+----------------------------+
|                          1 |
+----------------------------+

SELECT COERCIBILITY(CAST(1 AS CHAR));
+-------------------------------+
| COERCIBILITY(CAST(1 AS CHAR)) |
+-------------------------------+
|                             2 |
+-------------------------------+

SELECT COERCIBILITY(USER());
+----------------------+
| COERCIBILITY(USER()) |
+----------------------+
|                    3 |
+----------------------+

SELECT COERCIBILITY('abc');
+---------------------+
| COERCIBILITY('abc') |
+---------------------+
|                   4 |
+---------------------+

SELECT COERCIBILITY(1);
+-----------------+
| COERCIBILITY(1) |
+-----------------+
|               5 |
+-----------------+

SELECT COERCIBILITY(NULL);
+--------------------+
| COERCIBILITY(NULL) |
+--------------------+
|                  6 |
+--------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

COLLATION

Syntax

```
COLLATION(str)
```

Description

Returns the collation of the string argument. If `str` is not a string, it is considered as a binary string (so the function returns 'binary'). This applies to `NULL`, too. The return value is a string in the utf8 character set.

See Character Sets and Collations.

Examples

```
SELECT COLLATION('abc');
+------------------+
| COLLATION('abc')  |
+------------------+
| latin1_swedish_ci |
+------------------+

SELECT COLLATION(_utf8'abc');
+-----------------------+
| COLLATION(_utf8'abc') |
+-----------------------+
| utf8_general_ci       |
+-----------------------+
```

See Also

- String literals
- CAST()
- CONVERT()

This page is licensed: GPLv2, originally from fill_help_tables.sql

CONNECTION_ID

Syntax

```
CONNECTION_ID()
```

Description

Returns the connection ID for the connection. Every connection (including events) has an ID that is unique among the set of currently connected clients.

Returns `MYSQL_TYPE_LONG`, or int(10).

Examples

```
SELECT CONNECTION_ID();
+-----------------+
| CONNECTION_ID() |
+-----------------+
|               3 |
+-----------------+
```

See Also

- SHOW PROCESSLIST
- INFORMATION_SCHEMA.PROCESSLIST

This page is licensed: GPLv2, originally from fill_help_tables.sql

CURRENT_ROLE

Syntax

```
CURRENT_ROLE, CURRENT_ROLE()
```

Description

Returns the current role name. The return value is a string in the utf8 character set.

If there is no current role, `NULL` is returned.

USER() returns the combination of user and host used to login. CURRENT_USER() returns the account used to determine current connection's privileges.

Statements using the `CURRENT_ROLE` function are not safe for statement-based replication.

Examples

```
SELECT CURRENT_ROLE;
+--------------+
| CURRENT_ROLE |
+--------------+
| NULL         |
+--------------+

SET ROLE staff;

SELECT CURRENT_ROLE;
+--------------+
| CURRENT_ROLE |
+--------------+
| staff        |
+--------------+
```

This page is licensed: CC BY-SA / Gnu FDL

CURRENT_USER

Syntax

```
CURRENT_USER, CURRENT_USER()
```

Description

Returns the user name and host name combination for the MariaDB account that the server used to authenticate the current client. This account determines your access privileges. The return value is a string in the utf8 character set.

The value of `CURRENT_USER()` can differ from the value of USER(). CURRENT_ROLE() returns the current active role.

Statements using the `CURRENT_USER` function are not safe for statement-based replication.

Examples

```
shell> mysql --user="anonymous"

SELECT USER(),CURRENT_USER();
+---------------------+----------------+
| USER()              | CURRENT_USER() |
+---------------------+----------------+
| anonymous@localhost | @localhost     |
+---------------------+----------------+
```

When calling `CURRENT_USER()` in a stored procedure, it returns the owner of the stored procedure, as defined with `DEFINER`.

See Also

- USER()
- SESSION_USER()
- CREATE PROCEDURE

This page is licensed: GPLv2, originally from fill_help_tables.sql

DATABASE

Syntax

```
DATABASE()
SCHEMA()
```

Description

Returns the default (current) database name as a string in the utf8 character set. If there is no default database, `DATABASE()` returns `NULL`. Within a stored routine, the default database is the database that the routine is associated with, which is not necessarily the same as the database that is the default in the calling context.

`SCHEMA()` is a synonym for `DATABASE()`.

To select a default database, the USE statement can be run. Another way to set the default database is specifying its name at mariadb command line client startup.

Examples

```
SELECT DATABASE();
+------------+
| DATABASE() |
+------------+
| NULL       |
+------------+

USE test;
Database changed

SELECT DATABASE();
+------------+
| DATABASE() |
+------------+
| test       |
+------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

DECODE_HISTOGRAM

Syntax

```
DECODE_HISTOGRAM(hist_type,histogram)
```

Description

Returns a string of comma separated numeric values corresponding to a probability distribution represented by the histogram of type `hist_type` (`SINGLE_PREC_HB` or `DOUBLE_PREC_HB`). The `hist_type` and `histogram` would be commonly used from the mysql.column_stats table.

See Histogram Based Statistics for details.

Examples

```
CREATE TABLE origin (
  i INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
  v INT UNSIGNED NOT NULL
);

INSERT INTO origin(v) VALUES
  (1),(2),(3),(4),(5),(10),(20),
  (30),(40),(50),(60),(70),(80),
  (90),(100),(200),(400),(800);

SET histogram_size=10,histogram_type=SINGLE_PREC_HB;

ANALYZE TABLE origin PERSISTENT FOR ALL;
+-------------+---------+----------+----------------------------------------+
| Table       | Op      | Msg_type | Msg_text                               |
+-------------+---------+----------+----------------------------------------+
| test.origin | analyze | status   | Engine-independent statistics collected |
| test.origin | analyze | status   | OK                                     |
+-------------+---------+----------+----------------------------------------+

SELECT db_name,table_name,column_name,hist_type,
  hex(histogram),decode_histogram(hist_type,histogram)
  FROM mysql.column_stats WHERE db_name='test' and table_name='origin';
+---------+------------+-------------+----------------+----------------------+--------------------------
---------------------------------------+
| db_name | table_name | column_name | hist_type      | hex(histogram)       |
decode_histogram(hist_type,histogram)                          |
+---------+------------+-------------+----------------+----------------------+--------------------------

```

This page is licensed: CC BY-SA / Gnu FDL

DEFAULT

Syntax

```
DEFAULT(col_name)
```

Description

Returns the default value for a table column. If the column has no default value (and is not `NULLABLE` - `NULLABLE` fields have a `NULL` default), an error is returned.

For integer columns using AUTO_INCREMENT, `0` is returned.

When using `DEFAULT` as a value to set in an INSERT or UPDATE statement, you can use the bare keyword `DEFAULT` without the parentheses and argument to refer to the column in context. You can only use `DEFAULT` as a bare keyword if you are using it alone without a surrounding expression or function.

Examples

Select only non-default values for a column:

```
SELECT i FROM t WHERE i != DEFAULT(i);
```

Update values to be one greater than the default value:

```
UPDATE t SET i = DEFAULT(i)+1 WHERE i < 100;
```

When referring to the default value exactly in `UPDATE` or `INSERT`, you can omit the argument:

```
INSERT INTO t (i) VALUES (DEFAULT);
UPDATE t SET i = DEFAULT WHERE i < 100;
```

```
CREATE OR REPLACE TABLE t (
  i INT NOT NULL AUTO_INCREMENT,
  j INT NOT NULL,
  k INT DEFAULT 3,
  l INT NOT NULL DEFAULT 4,
  m INT,
  PRIMARY KEY (i)
);

DESC t;
+-------+---------+------+-----+---------+----------------+
| Field | Type    | Null | Key | Default | Extra          |
+-------+---------+------+-----+---------+----------------+
| i     | int(11) | NO   | PRI | NULL    | auto_increment |
| j     | int(11) | NO   |     | NULL    |                |

FOUND_ROWS

Syntax

```
FOUND_ROWS()
```

Description

A SELECT statement may include a LIMIT clause to restrict the number of rows the server returns to the client. In some cases, it is desirable to know how many rows the statement would have returned without the LIMIT, but without running the statement again. To obtain this row count, include an SQL_CALC_FOUND_ROWS option in the `SELECT` statement, and then invoke `FOUND_ROWS()` afterwards.

You can also use `FOUND_ROWS()` to obtain the number of rows returned by a `SELECT` which does not contain a `LIMIT` clause. In this case you don't need to use the `SQL_CALC_FOUND_ROWS` option. This can be useful for example in a stored procedure.

Also, this function works with some other statements which return a result set, including SHOW, DESC and HELP. For DELETE … RETURNING you should use ROW_COUNT(). It also works as a prepared statement, or after executing a prepared statement.

Statements which don't return any results don't affect `FOUND_ROWS()` - the previous value will still be returned.

Warning: When used after a CALL statement, this function returns the number of rows selected by the last query in the procedure, not by the whole procedure.

Statements using the `FOUND_ROWS()` function are not safe for statement-based replication.

Examples

```
SHOW ENGINES\G
*************************** 1. row ***************************
      Engine: CSV
     Support: YES
     Comment: Stores tables as CSV files
Transactions: NO
          XA: NO
  Savepoints: NO
*************************** 2. row ***************************
      Engine: MRG_MyISAM
     Support: YES
     Comment: Collection of identical MyISAM tables
Transactions: NO
          XA: NO
  Savepoints: NO

...

*************************** 8. row ***************************
      Engine: PERFORMANCE_SCHEMA
     Support: YES
     Comment: Performance Schema

This page is licensed: GPLv2, originally from fill_help_tables.sql

LAST_INSERT_ID

Syntax

```
LAST_INSERT_ID(), LAST_INSERT_ID(expr)
```

Description

`LAST_INSERT_ID()` (no arguments) returns the first automatically generated value successfully inserted for an AUTO_INCREMENT column as a result of the most recently executed `INSERT` statement. The value of `LAST_INSERT_ID()` remains unchanged if no rows are successfully inserted.

If one gives an argument to `LAST_INSERT_ID()`, then it will return the value of the expression and the next call to `LAST_INSERT_ID()` will return the same value. The value is also sent to the client and can be accessed by the mysql_insert_id function.

For example, after inserting a row that generates an `AUTO_INCREMENT` value, you can get the value like this:

```
SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
|                9 |
+------------------+
```

You can also use `LAST_INSERT_ID()` to delete the last inserted row:

```
DELETE FROM product WHERE id = LAST_INSERT_ID();
```

If no rows were successfully inserted, `LAST_INSERT_ID()` returns 0.

You can also use INSERT…RETURNING for this purpose.

The value of `LAST_INSERT_ID()` will be consistent across all versions if all rows in the INSERT or UPDATE statement were successful.

The currently executing statement does not affect the value of `LAST_INSERT_ID()`. Suppose that you generate an `AUTO_INCREMENT` value with one statement, and then refer to `LAST_INSERT_ID()` in a multiple-row `INSERT` statement that inserts rows into a table with its own `AUTO_INCREMENT` column. The value of `LAST_INSERT_ID()` will remain stable in the second statement; its value for the second and later rows is not affected by the earlier row insertions. (However, if you mix references to `LAST_INSERT_ID()` and `LAST_INSERT_ID( expr )`, the effect is undefined.)

If the previous statement returned an error, the value of `LAST_INSERT_ID()` is undefined. For transactional tables, if the statement is rolled back due to an error, the value of `LAST_INSERT_ID()` is left undefined. For manual ROLLBACK, the value of `LAST_INSERT_ID()` is not restored to that before the transaction; it remains as it was at the point of the `ROLLBACK`.

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these kinds of objects. The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the new value will be seen by statements that follow the procedure call.
- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements will not see a changed value.

Examples

```
CREATE TABLE t (
  id INTEGER UNSIGNED AUTO_INCREMENT PRIMARY KEY,
  f VARCHAR(1))
ENGINE = InnoDB;

INSERT INTO t(f) VALUES('a');

SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
|                1 |
+------------------+

INSERT INTO t(f) VALUES('b');

INSERT INTO t(f) VALUES('c');

SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
|                3 |
+------------------+

INSERT INTO t(f) VALUES('d'),('e');

SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
|                4 |
+------------------+

SELECT * FROM t;
+----+------+
| id | f    |
+----+------+
|  1 | a    |
|  2 | b    |
|  3 | c    |
|  4 | d    |
|  5 | e    |
+----+------+

SELECT LAST_INSERT_ID(12);
+--------------------+
| LAST_INSERT_ID(12) |
+--------------------+
|                 12 |
+--------------------+

SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
|               12 |
+------------------+

INSERT INTO t(f) VALUES('f');

SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
|                6 |
+------------------+
```

```
SELECT * FROM t;
+----+------+
| id | f    |
+----+------+
|  1 | a    |
|  2 | b    |
|  3 | c    |
|  4 | d    |
|  5 | e    |
|  6 | f    |
+----+------+

SELECT LAST_INSERT_ID(12);
+--------------------+
| LAST_INSERT_ID(12) |
+--------------------+
|                 12 |
+--------------------+

INSERT INTO t(f) VALUES('g');

SELECT * FROM t;
+----+------+
| id | f    |
+----+------+
|  1 | a    |
|  2 | b    |
|  3 | c    |
|  4 | d    |
|  5 | e    |
|  6 | f    |
|  7 | g    |
+----+------+
```

LAST_VALUE

Syntax

```
LAST_VALUE(expr,[expr,...])
```

```
LAST_VALUE(expr) OVER (
  [ PARTITION BY partition_expression ]
  [ ORDER BY order_list ]
)
```

Description

`LAST_VALUE()` evaluates all expressions and returns the last. This is useful together with setting user variables to a value with @var:=expr, for example when you want to get data of rows updated/deleted without having to do two queries against the table.

`LAST_VALUE` can be used as a window function.

Returns `NULL` if no last value exists.

Examples

```
CREATE TABLE t1 (a int, b int);
INSERT INTO t1 VALUES(1,10),(2,20);
DELETE FROM t1 WHERE a=1 AND last_value(@a:=a,@b:=b,1);
SELECT @a,@b;
+------+------+
| @a   | @b   |
+------+------+
|    1 |   10 |
+------+------+
```

As a window function:

```
CREATE TABLE t1 (
  pk int primary key,
  a int,
  b int,
  c char(10),
  d decimal(10, 3),
  e real
);

INSERT INTO t1 VALUES
( 1, 0, 1,    'one',    0.1,  0.001),
( 2, 0, 2,    'two',    0.2,  0.002),
( 3, 0, 3,    'three',  0.3,  0.003),
( 4, 1, 2,    'three',  0.4,  0.004),
( 5, 1, 1,    'two',    0.5,  0.005),
( 6, 1, 1,    'one',    0.6,  0.006),
( 7, 2, NULL, 'n_one',  0.5,  0.007),
( 8, 2, 1,    'n_two',  NULL, 0.008),
( 9, 2, 2,    NULL,     0.7,  0.009),
(10, 2, 0,    'n_four', 0.8,  0.010),
(11, 2, 10,   NULL,     0.9,  NULL);

SELECT pk, FIRST_VALUE(pk) OVER (ORDER BY pk) AS first_asc,
           LAST_VALUE(pk) OVER (ORDER BY pk) AS last_asc,
           FIRST_VALUE(pk) OVER (ORDER BY pk DESC) AS first_desc,
           LAST_VALUE(pk) OVER (ORDER BY pk DESC) AS last_desc
FROM t1
ORDER BY pk DESC;

+----+-----------+----------+------------+-----------+
| pk | first_asc | last_asc | first_desc | last_desc |
+----+-----------+----------+------------+-----------+
| 11 |         1 |       11 |         11 |        11 |
| 10 |         1 |       10 |         11 |        10 |
|  9 |         1 |        9 |         11 |         9 |
|  8 |         1 |        8 |         11 |         8 |
|  7 |         1 |        7 |         11 |         7 |
|  6 |         1 |        6 |         11 |         6 |
|  5 |         1 |        5 |         11 |         5 |

PROCEDURE ANALYSE

Syntax

```
ANALYSE([max_elements[,max_memory]])
```

Description

This procedure is defined in the `sql/sql_analyse.cc` file. It examines the result from a query and returns an analysis of the results that suggests optimal data types for each column. To obtain this analysis, append `PROCEDURE ANALYSE` to the end of a SELECT statement:

```
SELECT ... FROM ... WHERE ... PROCEDURE ANALYSE([max_elements,[max_memory]])
```

For example:

```
SELECT col1, col2 FROM table1 PROCEDURE ANALYSE(10, 2000);
```

The results show some statistics for the values returned by the query, and propose an optimal data type for the columns. This can be helpful for checking your existing tables, or after importing new data. You may need to try different settings for the arguments so that `PROCEDURE ANALYSE()` does not suggest the `ENUM` data type when it is not appropriate.

The arguments are optional and are used as follows:

- max_elements (default 256) is the maximum number of distinct values that analyse notices per column. This is used by analyse to check whether the optimal data type should be of type `ENUM`; if there are more than max_elements distinct values, then `ENUM` is not a suggested type.
- max_memory (default 8192) is the maximum amount of memory that analyse should allocate per column while trying to find all distinct values.

- PROCEDURE
- SELECT

This page is licensed: GPLv2, originally from fill_help_tables.sql

ROW_COUNT

Syntax

```
ROW_COUNT()
```

Description

`ROW_COUNT()` returns the number of rows updated, inserted or deleted by the preceding statement. This is the same as the row count that the mariadb client displays and the value from the mysql_affected_rows() C API function.

Generally:

- For statements which return a result set (such as SELECT, SHOW, DESC or HELP), returns -1, even when the result set is empty. This is also true for administrative statements, such as OPTIMIZE.
- For DML statements other than SELECT and for ALTER TABLE, returns the number of affected rows.
- For DDL statements (including TRUNCATE) and for other statements which don't return any result set (such as USE, DO, SIGNAL or DEALLOCATE PREPARE), returns 0.

For UPDATE, affected rows is by default the number of rows that were actually changed. If the CLIENT_FOUND_ROWS flag to mysql_real_connect() is specified when connecting to mariadbd, affected rows is instead the number of rows matched by the WHERE clause.

For REPLACE, deleted rows are also counted. So, if REPLACE deletes a row and adds a new row, `ROW_COUNT()` returns 2.

For INSERT … ON DUPLICATE KEY, values returned are as follows:

- 0: an existing row is set to its current values, and the `CLIENT_FOUND_ROWS` is not set.
- 1: the values are inserted as a new row, or an existing row is set to its current values, and the `CLIENT_FOUND_ROWS` is set.
- 2: an existing row is updated with new values.

`ROW_COUNT()` does not take into account rows that are not directly deleted/updated by the last statement. This means that rows deleted by foreign keys or triggers are not counted.

Warning: You can use `ROW_COUNT()` with prepared statements, but you need to call it after `EXECUTE`, not after DEALLOCATE PREPARE, because the row count for allocate prepare is always 0.

Warning: When used after a CALL statement, this function returns the number of rows affected by the last statement in the procedure, not by the whole procedure.

Warning: After INSERT DELAYED, `ROW_COUNT()` returns the number of the rows you tried to insert, not the number of the successful writes.

This information can also be found in the diagnostics area.

Statements using the `ROW_COUNT()` function are not safe for statement-based replication.

Examples

```
CREATE TABLE t (A INT);

INSERT INTO t VALUES(1),(2),(3);

SELECT ROW_COUNT();
+-------------+
| ROW_COUNT() |
+-------------+
|           3 |
+-------------+

DELETE FROM t WHERE A IN(1,2);

SELECT ROW_COUNT();
+-------------+
| ROW_COUNT() |
+-------------+
|           2 |
+-------------+
```

Example with prepared statements:

```
SET @q = 'INSERT INTO t VALUES(1),(2),(3);';

PREPARE stmt FROM @q;

EXECUTE stmt;
Query OK, 3 rows affected (0.39 sec)
Records: 3  Duplicates: 0  Warnings: 0

SELECT ROW_COUNT();
+-------------+
| ROW_COUNT() |
+-------------+
|           3 |
+-------------+
```

ROWNUM

> **Note:**
>
> `ROWNUM()` is available from MariaDB 10.6.1.

Syntax

```
ROWNUM()
```

In Oracle mode one can just use `ROWNUM`, without the parentheses.

Description

`ROWNUM()` returns the current number of accepted rows in the current context. It main purpose is to emulate the ROWNUM pseudo column in Oracle. For MariaDB native applications, we recommend the usage of LIMIT, as it is easier to use and gives more predictable results than the usage of `ROWNUM()`.

The main difference between using `LIMIT` and `ROWNUM()` to limit the rows in the result is that `LIMIT` works on the result set while `ROWNUM` works on the number of accepted rows (before any `ORDER` or `GROUP BY` clauses).

The following queries will return the same results:

```
SELECT * FROM t1 LIMIT 10;
SELECT * FROM t1 WHERE ROWNUM() <= 10;
```

While the following may return different results based on in which orders the rows are found:

```
SELECT * FROM t1 ORDER BY a LIMIT 10;
SELECT * FROM t1 ORDER BY a WHERE ROWNUM() <= 10;
```

The recommended way to use `ROWNUM` to limit the number of returned rows and get predictable results is to have the query in a subquery and test for `ROWNUM()` in the outer query:

```
SELECT * FROM (SELECT * FROM t1 ORDER BY a) WHERE ROWNUM() <= 10;
```

`ROWNUM()` can be used in the following contexts:

- SELECT
- INSERT
- UPDATE
- DELETE
- LOAD DATA INFILE

Used in other contexts, `ROWNUM()` will return 0.

Examples

```
INSERT INTO t1 VALUES (1,ROWNUM()),(2,ROWNUM()),(3,ROWNUM());

INSERT INTO t1 VALUES (1),(2) RETURNING a, ROWNUM();

UPDATE t1 SET row_num_column=ROWNUM();

DELETE FROM t1 WHERE a < 10 AND ROWNUM() < 2;

LOAD DATA INFILE 'filename' INTO TABLE t1 fields terminated BY ','
  lines terminated BY "\r\n" (a,b) SET c=ROWNUM();
```

Optimizations

In many cases where `ROWNUM()` is used, MariaDB will use the same optimizations it uses with LIMIT.

`LIMIT` optimization is possible when using `ROWNUM` in the following manner:

- When one is in a top level `WHERE` clause comparing `ROWNUM()` with a numerical constant using any of the following expressions:
  - `ROWNUM()` < number.
  - `ROWNUM()` <= number.
  - `ROWNUM()` = 1 `ROWNUM()` can be also be the right argument to the comparison function.

In the above cases, `LIMIT` optimization can be done in the following cases:

- For the current subquery when the `ROWNUM` comparison is done on the top level:

```
SELECT * FROM t1 WHERE ROWNUM() <= 2 AND t1.a > 0
```

- For an inner subquery, when the upper level has only a `ROWNUM()` comparison in the `WHERE` clause:

```
SELECT * FROM (SELECT * FROM t1) AS t WHERE ROWNUM() <= 2
```

Other Changes Related to ROWNUM

When `ROWNUM()` is used anywhere in a query, the optimization to ignore `ORDER BY` in subqueries are disabled.

This was done to get the following common Oracle query to work as expected:

```
SELECT * FROM (SELECT * FROM t1 ORDER BY a DESC) AS t WHERE rownum() <= 2;
```

By default, MariaDB ignores any `ORDER BY` in subqueries both because the SQL standard defines results sets in subqueries to be un-ordered and because of performance reasons (especially when using views in subqueries). See MDEV-3926 "Wrong result with `GROUP BY ... WITH ROLLUP`" for a discussion of this topic.

Other Considerations

While MariaDB tries to emulate Oracle's usage of `ROWNUM()` as closely as possible, there are cases where the result is different:

- When the optimizer finds rows in a different order (because of different storage methods or optimization). This may also happen in Oracle if one adds or deletes an index, in which case the rows may be found in a different order.

Note that usage of `ROWNUM()` in functions or stored procedures will use their own context, not the caller's context.

SCHEMA

Syntax

```
SCHEMA()
```

Description

This function is a synonym for DATABASE().

This page is licensed: GPLv2, originally from fill_help_tables.sql

SESSION_USER

Syntax

```
SESSION_USER()
```

Description

CURRENT

Shows the value of CURRENT_USER() when the session was created, that is, it shows a `user@host` pair from the mysql.global_priv table, like `CURRENT_USER()`, but unlike `CURRENT_USER()` it will not change inside stored routines and views. This is SQL Standard behavior for the `SESSION_USER` function.

< 11.7

`SESSION_USER()` is a synonym for USER().

Backward-compatible behavior can be restored by setting old mode to SESSION_USER_IS_USER.

This page is licensed: GPLv2, originally from fill_help_tables.sql

SYSTEM_USER

Syntax

```
SYSTEM_USER()
```

Description

`SYSTEM_USER()` is a synonym for USER().

This page is licensed: GPLv2, originally from fill_help_tables.sql

USER

Syntax

```
USER()
```

Description

Returns the current MariaDB user name and host name, given when authenticating to MariaDB, as a string in the utf8 character set.

> **Warning:**
>
> The value of `USER()` may differ from the value of CURRENT_USER(), which is the user used to authenticate the current client. CURRENT_ROLE() returns the currently active role.

CURRENT

`SYSTEM_USER()` is a synonym for `USER()`.

< 11.7

`SYSTEM_USER()` and SESSION_USER are synonyms for `USER()`.

Statements using the `USER()` function or one of its synonyms are not safe for statement level replication.

Examples

```
shell> mysql --user="anonymous"

SELECT USER(),CURRENT_USER();
+---------------------+----------------+
| USER()              | CURRENT_USER() |
+---------------------+----------------+
| anonymous@localhost | @localhost     |
+---------------------+----------------+
```

To select only the IP address, use SUBSTRING_INDEX(),

```
SELECT SUBSTRING_INDEX(USER(), '@', -1);
+---------------------------------+
| SUBSTRING_INDEX(USER(), '@', -1) |
+---------------------------------+
| 192.168.0.101                   |
+---------------------------------+
```

See Also

- CURRENT_USER()

This page is licensed: GPLv2, originally from fill_help_tables.sql

VERSION

Syntax

```
VERSION()
```

Description

Returns a string that indicates the MariaDB server version. The string uses the utf8 character set.

Examples

```
SELECT VERSION();
+----------------+
| VERSION()      |
+----------------+
| 10.4.7-MariaDB |
+----------------+
```

The `VERSION()` string may have one or more of the following suffixes:

Suffix	Description
-embedded	The server is an embedded server (libmariadbd).
-log	General logging, slow logging or binary (replication) logging is enabled.
-debug	The server is compiled for debugging.
-valgrind	The server is compiled to be instrumented with valgrind.

Changing the Version String

Some old legacy code may break because they are parsing the `VERSION` string and expecting a MySQL string or a simple version string like Joomla til API17, see MDEV-7780.

You can fool these applications by setting the version string from the command line or the `my.cnf` files with –version=….

FORMAT_BYTES

> **Note:**
>
> `FORMAT_BYTES` is available from MariaDB 11.8.

Syntax

```
FORMAT_BYTES(double)
```

Description

Given a byte count, returns a string consisting of a value and the units in a human-readable format. The units will be in bytes, KiB (kibibytes), MiB (mebibytes), GiB (gibibytes), TiB (tebibytes), PiB (pebibytes) or EiB (exbibytes).

The binary prefixes (kibi, mebi, gibi, tebi, pebi and exbi) were created in December 1998 by the International Electrotechnical Commission to avoid possible ambiguity, as the widely-used prefixes kilo, mega, giga, tera, peta and exa can be used to refer to both the power-of-10 decimal system multipliers and the power-of-two binary system multipliers.

This function is similar to the Sys Schema format_bytes function, except that function does not display exbibytes.

Examples

```
SELECT FORMAT_BYTES(1000)FORMAT_BYTES(1024);
+-------------------+-------------------+
| FORMAT_BYTES(1000) | FORMAT_BYTES(1024) |
+-------------------+-------------------+
| 1000 bytes         | 1.00 KiB           |

| FORMAT_BYTES(1000000000000000) | FORMAT_BYTES(1125899906842624) |
+--------------------------------+--------------------------------+
| 909.49 TiB                     | 1.00 PiB                       |
+--------------------------------+--------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

GET_LOCK

Syntax

```
GET_LOCK(str,timeout)
```

Description

Tries to obtain a lock with a name given by the string `str`, using a timeout of `timeout` seconds. Returns `1` if the lock was obtained successfully, `0` if the attempt timed out (for example, because another client has previously locked the name), or `NULL` if an error occurred (such as running out of memory or the thread was killed with mariadb-admin kill).

A lock is released with RELEASE_LOCK(), when the connection terminates (either normally or abnormally). A connection can hold multiple locks at the same time, so a lock that is no longer needed needs to be explicitly released.

The IS_FREE_LOCK function returns whether a specified lock is free or not, and the IS_USED_LOCK whether the function is in use or not.

Locks obtained with `GET_LOCK()` do not interact with transactions. That is, committing a transaction does not release any such locks obtained during the transaction.

It is also possible to recursively set the same lock. If a lock with the same name is set `n` times, it needs to be released `n` times as well.

`str` is case insensitive for `GET_LOCK()` and related functions. If `str` is an empty string or `NULL`, `GET_LOCK()` returns `NULL` and does nothing. `timeout` supports microseconds.

If the metadata_lock_info plugin is installed, locks acquired with this function are visible in the Information Schema METADATA_LOCK_INFO table.

This function can be used to implement application locks or to simulate record locks. Names are locked on a server-wide basis. If a name has been locked by one client, `GET_LOCK()` blocks any request by another client for a lock with the same name. This allows clients that agree on a given lock name to use the name to perform cooperative advisory locking. But be aware that it also allows a client that is not among the set of cooperating clients to lock a name, either inadvertently or deliberately, and thus prevent any of the cooperating clients from locking that name. One way to reduce the likelihood of this is to use lock names that are database-specific or application-specific. For example, use lock names of the form `db_name.str` or `app_name.str`.

Statements using the `GET_LOCK` function are not safe for statement-based replication.

The patch to permit multiple locks was contributed by Konstantin “Kostja” Osipov (MDEV-3917).

Examples

```
SELECT GET_LOCK('lock1',10);
+----------------------+
| GET_LOCK('lock1',10) |
+----------------------+
|                    1 |
+----------------------+

SELECT IS_FREE_LOCK('lock1'), IS_USED_LOCK('lock1');
+-----------------------+-----------------------+
| IS_FREE_LOCK('lock1') | IS_USED_LOCK('lock1') |
+-----------------------+-----------------------+
|                     0 |                    46 |
+-----------------------+-----------------------+

SELECT IS_FREE_LOCK('lock2'), IS_USED_LOCK('lock2');
+-----------------------+-----------------------+
| IS_FREE_LOCK('lock2') | IS_USED_LOCK('lock2') |
+-----------------------+-----------------------+
|                     1 |                  NULL |
+-----------------------+-----------------------+
```

Multiple locks can be held:

```
SELECT GET_LOCK('lock2',10);
+---------------------+
| GET_LOCK('lock2',10) |
+---------------------+
|                   1 |
+---------------------+

SELECT IS_FREE_LOCK('lock1'), IS_FREE_LOCK('lock2');
+----------------------+----------------------+
| IS_FREE_LOCK('lock1') | IS_FREE_LOCK('lock2') |
+----------------------+----------------------+
|                    0 |                    0 |
+----------------------+----------------------+

SELECT RELEASE_LOCK('lock1'), RELEASE_LOCK('lock2');
+----------------------+----------------------+
| RELEASE_LOCK('lock1') | RELEASE_LOCK('lock2') |
+----------------------+----------------------+
|                    1 |                    1 |
+----------------------+----------------------+
```

It is possible to hold the same lock recursively. This example is viewed using the metadata_lock_info plugin:

```
SELECT GET_LOCK('lock3',10);
+---------------------+
| GET_LOCK('lock3',10) |
+---------------------+
|                   1 |
+---------------------+

SELECT GET_LOCK('lock3',10);
+---------------------+
| GET_LOCK('lock3',10) |
+---------------------+
|                   1 |
+---------------------+

SELECT * FROM INFORMATION_SCHEMA.METADATA_LOCK_INFO;
+-----------+--------------------+---------------+-----------+--------------+------------+
| THREAD_ID | LOCK_MODE          | LOCK_DURATION | LOCK_TYPE | TABLE_SCHEMA | TABLE_NAME |
+-----------+--------------------+---------------+-----------+--------------+------------+
|        46 | MDL_SHARED_NO_WRITE | NULL          | User lock | lock3        |            |
+-----------+--------------------+---------------+-----------+--------------+------------+

SELECT RELEASE_LOCK('lock3');
+----------------------+
| RELEASE_LOCK('lock3') |
+----------------------+
|                    1 |
+----------------------+

SELECT * FROM INFORMATION_SCHEMA.METADATA_LOCK_INFO;
+-----------+--------------------+---------------+-----------+--------------+------------+
| THREAD_ID | LOCK_MODE          | LOCK_DURATION | LOCK_TYPE | TABLE_SCHEMA | TABLE_NAME |
+-----------+--------------------+---------------+-----------+--------------+------------+
|        46 | MDL_SHARED_NO_WRITE | NULL          | User lock | lock3        |            |
+-----------+--------------------+---------------+-----------+--------------+------------+

SELECT RELEASE_LOCK('lock3');
+----------------------+
| RELEASE_LOCK('lock3') |
+----------------------+
|                    1 |
+----------------------+

SELECT * FROM INFORMATION_SCHEMA.METADATA_LOCK_INFO;
Empty set (0.000 sec)
```

Timeout example: Connection 1:

```
SELECT GET_LOCK('lock4',10);
+----------------------+
| GET_LOCK('lock4',10) |
+----------------------+
|                    1 |
+----------------------+
```

Connection 2:

```
SELECT GET_LOCK('lock4',10);
```

After 10 seconds…

```
+----------------------+
| GET_LOCK('lock4',10) |
+----------------------+
|                    0 |
+----------------------+
```

Deadlocks are automatically detected and resolved. Connection 1:

```
SELECT GET_LOCK('lock5',10);
+----------------------+
| GET_LOCK('lock5',10) |
+----------------------+
|                    1 |
+----------------------+
```

Connection 2:

```
SELECT GET_LOCK('lock6',10);
+----------------------+
| GET_LOCK('lock6',10) |
+----------------------+
|                    1 |
+----------------------+
```

Connection 1:

```
SELECT GET_LOCK('lock6',10);
+----------------------+
| GET_LOCK('lock6',10) |
+----------------------+
|                    0 |
+----------------------+
```

Connection 2:

```
SELECT GET_LOCK('lock5',10);
ERROR 1213 (40001): Deadlock found when trying to get lock; try restarting transaction
```

INET6_ATON

Syntax

```
INET6_ATON(expr)
```

Description

Given an IPv6 or IPv4 network address as a string, returns a binary string that represents the numeric value of the address.

No trailing zone ID's or trailing network masks are permitted. For IPv4 addresses, or IPv6 addresses with IPv4 address parts, no classful addresses or trailing port numbers are permitted and octal numbers are not supported.

The returned binary string will be VARBINARY(16) or VARBINARY(4) for IPv6 and IPv4 addresses respectively.

Returns `NULL` if the argument is not understood.

MariaDB starting with 10.5.0

> **CURRENT**
>
> `INET6_ATON` can take INET6 as an argument.
>
> **< 10.5**
>
> `INET6_ATON` **cannot** take INET6 as an argument.

Examples

```
SELECT HEX(INET6_ATON('10.0.1.1'));
+----------------------------+
| HEX(INET6_ATON('10.0.1.1')) |
+----------------------------+
| 0A000101                   |
+----------------------------+

SELECT HEX(INET6_ATON('48f3::d432:1431:ba23:846f'));
+-------------------------------------------+
| HEX(INET6_ATON('48f3::d432:1431:ba23:846f')) |
+-------------------------------------------+
| 48F3000000000000D4321431BA23846F             |
+-------------------------------------------+
```

See Also

This page is licensed: CC BY-SA / Gnu FDL

INET6_NTOA

Syntax

```
INET6_NTOA(expr)
```

Description

Given an IPv6 or IPv4 network address as a numeric binary string, returns the address as a nonbinary string in the connection character set.

The return string is lowercase, and is platform independent, since it does not use functions specific to the operating system. It has a maximum length of 39 characters.

Returns `NULL` if the argument is not understood.

Examples

```
SELECT INET6_NTOA(UNHEX('0A000101'));
+------------------------------+
| INET6_NTOA(UNHEX('0A000101')) |
+------------------------------+
| 10.0.1.1                     |
+------------------------------+

SELECT INET6_NTOA(UNHEX('48F3000000000000D4321431BA23846F'));
+-------------------------------------------------------+
| INET6_NTOA(UNHEX('48F3000000000000D4321431BA23846F')) |
+-------------------------------------------------------+
| 48f3::d432:1431:ba23:846f                             |
+-------------------------------------------------------+
```

See Also

- INET6_ATON()
- INET_NTOA()

This page is licensed: CC BY-SA / Gnu FDL

INET_ATON

Syntax

```
INET_ATON(expr)
```

Description

Given the dotted-quad representation of an IPv4 network address as a string, returns an integer that represents the numeric value of the address. Addresses may be 4- or 8-byte addresses.

Returns `NULL` if the argument is not understood.

Examples

```
SELECT INET_ATON('192.168.1.1');
+--------------------------+
| INET_ATON('192.168.1.1') |
+--------------------------+
|               3232235777 |
+--------------------------+
```

This is calculated as follows: 192 x 2563 + 168 x 256 2 + 1 x 256 + 1.

See Also

- INET6_ATON()
- INET_NTOA()

This page is licensed: GPLv2, originally from fill_help_tables.sql

INET_NTOA

Syntax

```
INET_NTOA(expr)
```

Description

Given a numeric IPv4 network address in network byte order (4 or 8 byte), returns the dotted-quad representation of the address as a string.

Examples

```
SELECT INET_NTOA(3232235777);
+-----------------------+
| INET_NTOA(3232235777) |
+-----------------------+
| 192.168.1.1           |
+-----------------------+
```

192.168.1.1 corresponds to 3232235777 since 192 x 2563 + 168 x 256 2 + 1 x 256 + 1 = 3232235777.

See Also

- INET6_NTOA()
- INET_ATON()

This page is licensed: GPLv2, originally from fill_help_tables.sql

IS_FREE_LOCK

Syntax

```
IS_FREE_LOCK(str)
```

Description

Checks whether the lock named `str` is free to use (that is, not locked). Returns `1` if the lock is free (no one is using the lock), `0` if the lock is in use, and `NULL` if an error occurs (such as an incorrect argument, like an empty string or `NULL`). `str` is case insensitive.

If the metadata_lock_info plugin is installed, the Information Schema metadata_lock_info table contains information about locks of this kind (as well as metadata locks).

Statements using the `IS_FREE_LOCK` function are not safe for statement-based replication.

See Also

- GET_LOCK
- RELEASE_LOCK
- IS_USED_LOCK
- RELEASE_ALL_LOCKS

This page is licensed: GPLv2, originally from fill_help_tables.sql

IS_IPV4

Syntax

```
IS_IPV4(expr)
```

Description

If the expression is a valid IPv4 address, returns 1, otherwise returns 0.

`IS_IPV4()` is stricter than INET_ATON(), but as strict as INET6_ATON(), in determining the validity of an IPv4 address. This implies that if IS_IPV4 returns 1, the same expression will always return a non-`NULL` result when passed to `INET_ATON()`, but that the reverse may not apply.

Examples

```
SELECT IS_IPV4('1110.0.1.1');
+----------------------+
| IS_IPV4('1110.0.1.1') |
+----------------------+
|                    0 |
+----------------------+

SELECT IS_IPV4('48f3::d432:1431:ba23:846f');
+--------------------------------------+
| IS_IPV4('48f3::d432:1431:ba23:846f') |
+--------------------------------------+
|                                    0 |
+--------------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

IS_IPV4_COMPAT

Syntax

```
IS_IPV4_COMPAT(expr)
```

Description

Returns 1 if a given numeric binary string IPv6 address, such as returned by INET6_ATON(), is IPv4-compatible, otherwise returns 0.

> **CURRENT**
>
> When the argument is not INET6, automatic implicit CAST to INET6 is applied. As a consequence, `IS_IPV4_COMPAT` now understands arguments in both text representation and binary(16) representation.
>
> **< 10.5**
>
> The function understands only binary(16) representation.

Examples

```
SELECT IS_IPV4_COMPAT(INET6_ATON('::10.0.1.1'));
+-----------------------------------------+
| IS_IPV4_COMPAT(INET6_ATON('::10.0.1.1')) |
+-----------------------------------------+
|                                       1 |
+-----------------------------------------+

SELECT IS_IPV4_COMPAT(INET6_ATON('::48f3::d432:1431:ba23:846f'));
+------------------------------------------------------------+
| IS_IPV4_COMPAT(INET6_ATON('::48f3::d432:1431:ba23:846f')) |
+------------------------------------------------------------+
|                                                          0 |
+------------------------------------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

IS_IPV4_MAPPED

Syntax

```
IS_IPV4_MAPPED(expr)
```

Description

Returns 1 if a given a numeric binary string IPv6 address, such as returned by INET6_ATON(), is a valid IPv4-mapped address, otherwise returns 0.

> **CURRENT**
>
> When the argument is not INET6, automatic implicit CAST to INET6 is applied. As a consequence, `IS_IPV4_MAPPED` now understands arguments in both text representation and binary(16) representation.
>
> **< 10.5**
>
> The function understands only binary(16) representation.

Examples

```
SELECT IS_IPV4_MAPPED(INET6_ATON('::10.0.1.1'));
+-----------------------------------------+
| IS_IPV4_MAPPED(INET6_ATON('::10.0.1.1')) |
+-----------------------------------------+
|                                       0 |
+-----------------------------------------+

SELECT IS_IPV4_MAPPED(INET6_ATON('::ffff:10.0.1.1'));
+-----------------------------------------------+
| IS_IPV4_MAPPED(INET6_ATON('::ffff:10.0.1.1')) |
+-----------------------------------------------+
|                                             1 |
+-----------------------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

IS_IPV6

Syntax

```
IS_IPV6(expr)
```

Description

Returns 1 if the expression is a valid IPv6 address specified as a string, otherwise returns 0. Does not consider IPv4 addresses to be valid IPv6 addresses.

Examples

```
SELECT IS_IPV6('48f3::d432:1431:ba23:846f');
+--------------------------------------+
| IS_IPV6('48f3::d432:1431:ba23:846f') |
+--------------------------------------+
|                                    1 |
+--------------------------------------+
1 row in set (0.02 sec)

SELECT IS_IPV6('10.0.1.1');
+---------------------+
| IS_IPV6('10.0.1.1') |
+---------------------+
|                   0 |
+---------------------+
```

IS_USED_LOCK

Syntax

```
IS_USED_LOCK(str)
```

Description

Checks whether the lock named `str` is in use (that is, locked). If so, it returns the connection identifier of the client that holds the lock. Otherwise, it returns `NULL`. `str` is case insensitive.

If the metadata_lock_info plugin is installed, the Information Schema metadata_lock_info table contains information about locks of this kind (as well as metadata locks).

Statements using the `IS_USED_LOCK` function are not safe for statement-based replication.

MASTER_GTID_WAIT

Syntax

```
MASTER_GTID_WAIT(gtid-list[, timeout)
```

Description

This function takes a string containing a comma-separated list of global transaction id's (similar to the value of, for example, gtid_binlog_pos). It waits until the value of gtid_slave_pos has the same or higher `seq_no` within all replication domains specified in the gtid-list; in other words, it waits until the replica has reached the specified GTID position.

An optional second argument gives a timeout in seconds. If the timeout expires before the specified GTID position is reached, then the function returns -1. Passing `NULL` or a negative number for the timeout means no timeout, and the function will wait indefinitely.

If the wait completes without a timeout, 0 is returned. Passing `NULL` for the gtid-list makes the function return `NULL` immediately, without waiting.

The gtid-list may be the empty string, in which case `MASTER_GTID_WAIT()` returns immediately. If the gtid-list contains fewer domains than gtid_slave_pos, then only those domains are waited upon. If gtid-list contains a domain that is not present in `@@gtid_slave_pos`, then `MASTER_GTID_WAIT()` will wait until an event containing such domain_id arrives on the replica (or until timed out or killed).

`MASTER_GTID_WAIT()` can be useful to ensure that a replica has caught up to a master. Simply take the value of gtid_binlog_pos on the master, and use it in a `MASTER_GTID_WAIT()` call on the replica; when the call completes, the replica will have caught up with that master position.

`MASTER_GTID_WAIT()` can also be used in client applications together with the last_gtid session variable. This is useful in a read-scaleout replication setup, where the application writes to a single master but divides the reads out to a number of replica to distribute the load. In such a setup, there is a risk that an application could first do an update on the master, and then a bit later do a read on a replica, and if the replica is not fast enough, the data read from the slave might not include the update just made, possibly confusing the application and/or the end-user. One way to avoid this is to request the value of last_gtid on the master just after the update. Then before doing the read on the replica, do a `MASTER_GTID_WAIT()` on the value obtained from the master; this will ensure that the read is not performed until the replica has replicated sufficiently far for the update to have become visible.

Note that `MASTER_GTID_WAIT()` can be used even if the replica is configured not to use GTID for connections (CHANGE MASTER TO master_use_gtid=no). This is because from MariaDB 10, GTIDs are always logged on the master server, and always recorded on the replica servers.

Differences to MASTER_POS_WAIT()

- `MASTER_GTID_WAIT()` is global; it waits for any master connection to reach the specified GTID position. MASTER_POS_WAIT() works only against a specific connection. This also means that while `MASTER_POS_WAIT()` aborts if its master connection is terminated with STOP REPLICA or due to an error, `MASTER_GTID_WAIT()` continues to wait while replicas are stopped.
- `MASTER_GTID_WAIT()` can take its timeout as a floating-point value, so a timeout in fractional seconds is supported, eg. `MASTER_GTID_WAIT("0-1-100", 0.5)`. (The minimum wait is one microsecond, 0.000001 seconds).
- `MASTER_GTID_WAIT()` allows one to specify a timeout of zero in order to do a non-blocking check to see if the replicas have progressed to a specific GTID position (`MASTER_POS_WAIT()` takes a zero timeout as meaning an

infinite wait). To do an infinite `MASTER_GTID_WAIT()`, specify a negative timeout, or omit the timeout argument.

- `MASTER_GTID_WAIT()` does not return the number of events executed since the wait started, nor does it return `NULL` if a replica thread is stopped. It always returns either 0 for successful wait completed, or -1 for timeout reached (or `NULL` if the specified gtid-pos is `NULL`).

Since `MASTER_GTID_WAIT()` looks only at the seq_no part of the GTIDs, not the server_id, care is needed if a replica becomes diverged from another server so that two different GTIDs with the same seq_no (in the same domain) arrive at the same server. This situation is in any case best avoided; setting gtid_strict_mode is recommended, as this will prevent any such out-of-order sequence numbers from ever being replicated on a replica.

This page is licensed: CC BY-SA / Gnu FDL

MASTER_POS_WAIT

Syntax

```
MASTER_POS_WAIT(log_name,log_pos[,timeout,["connection_name"]])
```

Description

This function is useful in replication for controlling primary/replica synchronization. It blocks until the replica has read and applied all updates up to the specified position (`log_name,log_pos`) in the primary's binary log. The return value is the number of log events the replica had to wait for to advance to the specified position. The function returns `NULL` if the replica SQL thread is not started, the replica's primary information is not initialized, the arguments are incorrect, or an error occurs. It returns -1 if the timeout has been exceeded. If the replica SQL thread stops while `MASTER_POS_WAIT()` is waiting, the function returns `NULL`. If the replica is past the specified position, the function returns immediately.

If a `timeout` value is specified, `MASTER_POS_WAIT()` stops waiting when `timeout` seconds have elapsed. `timeout` must be greater than 0; a zero or negative `timeout` means no `timeout`.

The `connection_name` is used when you are using multi-source-replication. If you don't specify it, it's set to the value of the default_master_connection system variable.

Statements using the `MASTER_POS_WAIT()` function are not safe for statement-based replication.

This page is licensed: GPLv2, originally from fill_help_tables.sql

NAME_CONST

Syntax

```
NAME_CONST(name,value)
```

Description

Returns the given value. When used to produce a result set column, `NAME_CONST()` causes the column to have the given name. The arguments should be constants.

This function is used internally when replicating stored procedures. It makes little sense to use it explicitly in SQL statements, and it was not supposed to be used like that.

```
SELECT NAME_CONST('myname', 14);
+--------+
| myname |
+--------+
|     14 |
+--------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

OLD_VALUE

Note:

This function is available from MariaDB 13.0.

Syntax

```
OLD_VALUE(val)
```

Description

In the `RETURNING` clause of an `UPDATE` statement, `OLD_VALUE()` returns the value before the update. The function is meaningful only in this context.

Examples

```
UPDATE t SET a=a+1 RETURNING OLD_VALUE(a) AS old, a as new;
+------+------+
| old  | new  |
+------+------+
|    1 |    2 |
+------+------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

RELEASE_ALL_LOCKS

Note:

`RELEASE_ALL_LOCKS` is available from MariaDB 10.5.2.

Syntax

```
RELEASE_ALL_LOCKS()
```

Description

Releases all named locks held by the current session. Returns the number of locks released, or `0` if none were held.

Statements using the `RELEASE_ALL_LOCKS` function are not safe for statement-based replication.

Examples

```
SELECT RELEASE_ALL_LOCKS();
+---------------------+
| RELEASE_ALL_LOCKS() |
+---------------------+
|                   0 |
+---------------------+

SELECT GET_LOCK('lock1',10);
+----------------------+
| GET_LOCK('lock1',10) |
+----------------------+
|                    1 |
+----------------------+

SELECT RELEASE_ALL_LOCKS();
+---------------------+
| RELEASE_ALL_LOCKS() |
+---------------------+
|                   1 |
+---------------------+
```

See Also

- GET_LOCK
- IS_FREE_LOCK
- IS_USED_LOCK
- RELEASE_LOCK

This page is licensed: CC BY-SA / Gnu FDL

RELEASE_LOCK

Syntax

```
RELEASE_LOCK(str)
```

Description

Releases the lock named by the string `str` that was obtained with GET_LOCK(). Returns `1` if the lock was released, `0` if the lock was not established by this connection (in which case the lock is not released), and `NULL` if the named lock did not exist. The lock does not exist if it was never obtained by a call to `GET_LOCK()` or if it has previously been released.

`str` is case insensitive. If `str` is an empty string or `NULL`, `RELEASE_LOCK()` returns `NULL` and does nothing.

Statements using the `RELEASE_LOCK` function are not safe for statement-based replication.

The DO statement is convenient to use with `RELEASE_LOCK()`.

Examples

Connection1:

```
SELECT GET_LOCK('lock1',10);
+----------------------+
| GET_LOCK('lock1',10) |
+----------------------+
|                    1 |
+----------------------+
```

Connection 2:

```
SELECT GET_LOCK('lock2',10);
+----------------------+
| GET_LOCK('lock2',10) |
+----------------------+
|                    1 |
+----------------------+
```

Connection 1:

```
SELECT RELEASE_LOCK('lock1'), RELEASE_LOCK('lock2'), RELEASE_LOCK('lock3');
+----------------------+----------------------+----------------------+
| RELEASE_LOCK('lock1') | RELEASE_LOCK('lock2') | RELEASE_LOCK('lock3') |
+----------------------+----------------------+----------------------+
|                    1 |                    0 |                 NULL |
+----------------------+----------------------+----------------------+
```

It is possible to hold the same lock recursively. This example is viewed using the metadata_lock_info plugin:

```
SELECT GET_LOCK('lock3',10);
+----------------------+
| GET_LOCK('lock3',10) |
+----------------------+
|                    1 |
+----------------------+

SELECT GET_LOCK('lock3',10);
+----------------------+
| GET_LOCK('lock3',10) |
+----------------------+
|                    1 |
+----------------------+

SELECT * FROM INFORMATION_SCHEMA.METADATA_LOCK_INFO;
+-----------+---------------------+---------------+-----------+--------------+------------+
| THREAD_ID | LOCK_MODE           | LOCK_DURATION | LOCK_TYPE | TABLE_SCHEMA | TABLE_NAME |
+-----------+---------------------+---------------+-----------+--------------+------------+
|        46 | MDL_SHARED_NO_WRITE | NULL          | User lock | lock3        |            |
+-----------+---------------------+---------------+-----------+--------------+------------+

SELECT RELEASE_LOCK('lock3');
+----------------------+
| RELEASE_LOCK('lock3') |
+----------------------+
|                    1 |
+----------------------+

SELECT * FROM INFORMATION_SCHEMA.METADATA_LOCK_INFO;
+-----------+---------------------+---------------+-----------+--------------+------------+
| THREAD_ID | LOCK_MODE           | LOCK_DURATION | LOCK_TYPE | TABLE_SCHEMA | TABLE_NAME |
+-----------+---------------------+---------------+-----------+--------------+------------+
|        46 | MDL_SHARED_NO_WRITE | NULL          | User lock | lock3        |            |
+-----------+---------------------+---------------+-----------+--------------+------------+

SELECT RELEASE_LOCK('lock3');
+----------------------+
| RELEASE_LOCK('lock3') |
+----------------------+
|                    1 |
+----------------------+

SELECT * FROM INFORMATION_SCHEMA.METADATA_LOCK_INFO;
Empty set (0.000 sec)
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

SLEEP

Syntax

```
SLEEP(duration)
```

Description

Sleeps (pauses) for the number of seconds given by the duration argument, then returns `0`. If `SLEEP()` is interrupted, it returns `1`. The duration may have a fractional part given in microseconds.

Statements using the SLEEP() function are not safe for statement-based replication.

Example

```
SELECT SLEEP(5.5);
+------------+
| SLEEP(5.5) |
+------------+
|          0 |
+------------+
1 row in set (5.50 sec)
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

SYS_GUID

> **Note:**
>
> `SYS_GUID` is available from MariaDB 10.6.1.

The `SYS_GUID` function was introduced to enhance Oracle compatibility. Similar functionality can be achieved with the UUID function.

Syntax

```
SYS_GUID()
```

Description

Returns a 16-byte globally unique identifier (GUID), similar to the UUID function, but without the `-` character.

Example

```
SELECT SYS_GUID();
+----------------------------------+
| SYS_GUID()                       |
+----------------------------------+
| 2C574E45BA2811EBB265F859713E4BE4 |
+----------------------------------+
```

See Also

- UUID
- UUID_SHORT
- UUID data type

This page is licensed: CC BY-SA / Gnu FDL

UUID

Syntax

```
UUID()
```

Description

Returns a Universally Unique Identifier (UUID) version 1. Functions to generate v4 and v7 UUIDs are available from MariaDB 11.7. See UUIDv4 and UUIDv7 respectively.

A UUID is designed as a number that is globally unique in space and time. Two calls to `UUID()` are expected to generate two different values, even if these calls are performed on two separate computers that are not connected to each other.

UUID() results are intended to be unique, but cannot always be relied upon to be unpredictable and unguessable.

A UUID is a 128-bit number represented by a utf8 string of five hexadecimal numbers in `aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee` format:

- The first three numbers are generated from a timestamp.
- The fourth number preserves temporal uniqueness in case the timestamp value loses monotonicity (for example, due to daylight saving time).
- The fifth number is an IEEE 802 node number that provides spatial uniqueness.
  A random number is substituted if the latter is not available (for example, because the host computer has no Ethernet card, or we do not know how to find the hardware address of an interface on your operating system). In this case, spatial uniqueness cannot be guaranteed. Nevertheless, a collision should have very low probability.

Currently, the MAC address of an interface is taken into account only on FreeBSD and Linux. On other operating systems, MariaDB uses a randomly generated 48-bit number.

Statements using the UUID() function are not safe for statement-based replication.

The function generates a UUIDv1 and the results are generated according to the “DCE 1.1:Remote Procedure Call” (Appendix A) CAE (Common Applications Environment) Specifications published by The Open Group in October 1997 (Document Number C706).

Examples

```
SELECT UUID();
+--------------------------------------+
| UUID()                               |
+--------------------------------------+
| cd41294a-afb0-11df-bc9b-00241dd75637 |
+--------------------------------------+
```

UUID_SHORT

Syntax

```
UUID_SHORT()
```

Description

Returns a “short” universally unique identifier as a 64-bit unsigned integer (rather than a string-form 128-bit identifier as returned by the UUID() function).

The value of `UUID_SHORT()` is guaranteed to be unique if the following conditions hold:

- The server_id of the current host is unique among your set of master and replica servers.
- `server_id` is between 0 and 255.
- You don’t set back your system time for your server between mariadbd restarts.
- You do not invoke `UUID_SHORT()` on average more than 16 million times per second between mariadbd restarts

The `UUID_SHORT()` return value is constructed this way:

```
(server_id & 255) << 56
+ (server_startup_time_in_seconds << 24)
+ incremented_variable++;
```

Statements using the UUID_SHORT() function are not safe for statement-based replication.

Examples

```
SELECT UUID_SHORT();
+-------------------+
| UUID_SHORT()      |
+-------------------+
| 21517162376069120 |
+-------------------+
```

```
CREATE TABLE t1 (a BIGINT UNSIGNED DEFAULT(uuid_short()) PRIMARY KEY);
INSERT INTO t1 VALUES(),();
SELECT * FROM t1;
+-------------------+
| a                 |
+-------------------+
| 98113699159474176 |
| 98113699159474177 |
+-------------------+
```

UUID_v4

> **Note:**
>
> `UUID_v4` is available from MariaDB 11.7.

It is possible to generate UUIDv4 and UUIDv7, in addition to UUIDv1.

Syntax

```
UUID_v4()
```

Description

Returns a Universally Unique Identifier (UUID) version 4. To generate a version 1 UUID, see the UUID function. To generate a version 7 UUID, see UUIDv7.

A UUID is designed as a number that is globally unique in space and time. Two calls to `UUID()` are expected to generate two different values, even if these calls are performed on two separate computers that are not connected to each other.

UUID_v4() results are intended to be unique, but cannot always be relied upon to be unpredictable and unguessable.

A UUID is a 128-bit number represented by a utf8 string of five hexadecimal numbers in `aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee` format.

Statements using the UUID_v4() function are not safe for statement-based replication.

Examples

```
SELECT UUID(),UUID_v4(),UUID_v7()\G
*************************** 1. row ***************************
  UUID(): 63ae8c92-799a-11ef-98b2-f859713e4be4
UUID_v4(): a2443495-1b94-415b-b6fa-fe8e79ba4812
UUID_v7(): 01921e85-f198-7490-9b89-7dd0d468543b

CREATE TABLE t1 (a INT PRIMARY KEY NOT NULL, u UUID DEFAULT UUID_v4(), UNIQUE KEY(u));
```

UUID_v7

> **Note:**
>
> `UUID_v7` is available from MariaDB 11.7.

It is possible to generate UUIDv4 and UUIDv7, in addition to UUIDv1.

Syntax

```
UUID_v7()
```

Description

Returns a Universally Unique Identifier (UUID) version 7. To generate a version 1 UUID, see the UUID function. To generate a version 4 UUID, see UUID_v4.

A UUID is designed as a number that is globally unique in space and time. Two calls to `UUID()` are expected to generate two different values, even if these calls are performed on two separate computers that are not connected to each other.

A UUID is a 128-bit number represented by a utf8 string of five hexadecimal numbers in `aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee` format.

Statements using the UUID_v7() function are not safe for statement-based replication.

Examples

```
SELECT UUID(),UUID_v4(),UUID_v7()\G
*************************** 1. row ***************************
  UUID(): 63ae8c92-799a-11ef-98b2-f859713e4be4
UUID_v4(): a2443495-1b94-415b-b6fa-fe8e79ba4812
UUID_v7(): 01921e85-f198-7490-9b89-7dd0d468543b

VALUES / VALUE

Syntax

```
VALUE(col_name)
```

Description

In an INSERT … ON DUPLICATE KEY UPDATE statement, you can use the `VALUES(col_name)` function in the UPDATE clause to refer to column values from the INSERT portion of the statement. In other words, `VALUES(col_name)` in the `UPDATE` clause refers to the value of col_name that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts.

The `VALUES()` function is meaningful only in `INSERT ... ON DUPLICATE KEY UPDATE` statements and returns `NULL` otherwise.

This function was renamed to `VALUE()`, because it's incompatible with the standard Table Value Constructors syntax.

The `VALUES()` function can still be used but only in `INSERT ... ON DUPLICATE KEY UPDATE` statements; it's a syntax error otherwise.

Examples

```
INSERT INTO t (a,b,c) VALUES (1,2,3),(4,5,6)
    ON DUPLICATE KEY UPDATE c=VALUE(a)+VALUE(b);
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

Special Functions

See Dynamic Columns Functions.

Manage schema-less data within relational tables. These functions, such as COLUMN_CREATE and COLUMN_GET, allow you to store and retrieve variable sets of columns in a single BLOB field.

See Galera Functions.

Interact with the Galera Cluster plugin. These functions provide internal status information and control mechanisms specific to synchronous multi-master replication nodes.

See Geographic Functions.

Process geospatial data. This collection of functions allows you to create, analyze, and manipulate geometric shapes like points, lines, and polygons within your database.

See JSON Functions.

Complete JSON Functions reference: JSON_EXTRACT(), JSON_SET(), JSON_REPLACE(), JSON_SEARCH() syntax for path queries, document updates, and value retrieval.

See Window Functions.

Explore window functions in MariaDB Server. This section details SQL functions that perform calculations across a set of table rows related to the current row, enabling advanced analytical queries.

This page is licensed: CC BY-SA / Gnu FDL

Dynamic Columns Functions

See COLUMN_ADD.

Update dynamic columns. This function adds or updates values within a dynamic column blob, returning the new blob content.

See COLUMN_CHECK.

Verify dynamic column integrity. This function checks if a blob containing dynamic columns is valid and returns 1 if it is, 0 otherwise.

See COLUMN_CREATE.

Create a dynamic column blob. This function generates a binary string containing specified column names and values for storage in a BLOB.

See COLUMN_DELETE.

Remove dynamic columns. This function deletes specified columns from a dynamic column blob and returns the updated blob.

See COLUMN_EXISTS.

Check for a dynamic column. This function returns 1 if a specified column exists within a dynamic column blob, and 0 otherwise.

See COLUMN_GET.

Retrieve a dynamic column value. This function extracts a specific column's value from a dynamic column blob, casting it to a specified type.

See COLUMN_JSON.

Convert dynamic columns to JSON. This function returns a JSON string representation of the data stored in a dynamic column blob.

See COLUMN_LIST.

List dynamic column names. This function returns a comma-separated list of all column names contained within a dynamic column blob.

This page is licensed: CC BY-SA / Gnu FDL

COLUMN_ADD

Syntax

```
COLUMN_ADD(dyncol_blob, column_nr, value [as type], [column_nr, value [as type]]...)
COLUMN_ADD(dyncol_blob, column_name, value [as type], [column_name, value [as type]]...)
```

Description

Adds or updates dynamic columns.

- `dyncol_blob` must be either a valid dynamic columns blob (for example, `COLUMN_CREATE` returns such blob), or an empty string.
- `column_name` specifies the name of the column to be added. If `dyncol_blob` already has a column with this name, it will be overwritten.

- `value` specifies the new value for the column. Passing a NULL value will cause the column to be deleted.
- `as type` is optional. See #datatypes section for a discussion about types.

The return value is a dynamic column blob after the modifications.

Examples

```
UPDATE t1 SET dyncol_blob=COLUMN_ADD(dyncol_blob, "column_name", "value") WHERE id=1;
```

Note: `COLUMN_ADD()` is a regular function (just like CONCAT()), hence, in order to update the value in the table you have to use the `UPDATE ... SET dynamic_col=COLUMN_ADD(dynamic_col, ....)` pattern.

This page is licensed: CC BY-SA / Gnu FDL

COLUMN_CHECK

Syntax

```
COLUMN_CHECK(dyncol_blob);
```

Description

Check if `dyncol_blob` is a valid packed dynamic columns blob. Return value of 1 means the blob is valid, return value of 0 means it is not.

Rationale:
Normally, one works with valid dynamic column blobs. Functions like COLUMN_CREATE, COLUMN_ADD, COLUMN_DELETE always return valid dynamic column blobs. However, if a dynamic column blob is accidentally truncated, or transcoded from one character set to another, it will be corrupted. This function can be used to check if a value in a blob field is a valid dynamic column blob.

This page is licensed: CC BY-SA / Gnu FDL

COLUMN_CREATE

Syntax

```
COLUMN_CREATE(column_nr, value [as type], [column_nr, value [as type]]...)
COLUMN_CREATE(column_name, value [as type], [column_name, value [as type]]...)
```

Description

Returns a dynamic columns blob that stores the specified columns with values.

The return value is suitable for

- storing in a table;
- further modification with other dynamic columns functions.

The **`as type`** part allows one to specify the value type. In most cases, this is redundant because MariaDB will be able to deduce the type of the value. Explicit type specification may be needed when the type of the value is not apparent. For example, a literal `'2012-12-01'` has a CHAR type by default, one will need to specify `'2012-12-01' AS DATE` to have it stored as a date. See Dynamic Columns:Datatypes for further details.

Examples

```
INSERT INTO tbl SET dyncol_blob=COLUMN_CREATE("column_name", "value");
```

This page is licensed: CC BY-SA / Gnu FDL

COLUMN_DELETE

Syntax

```
COLUMN_DELETE(dyncol_blob, column_nr, column_nr...)
COLUMN_DELETE(dyncol_blob, column_name, column_name...)
```

Description

Deletes a dynamic column with the specified name. Multiple names can be given. The return value is a dynamic column blob after the modification.

This page is licensed: CC BY-SA / Gnu FDL

COLUMN_EXISTS

Syntax

```
COLUMN_EXISTS(dyncol_blob, column_nr)
COLUMN_EXISTS(dyncol_blob, column_name)
```

Description

Checks if a column with name `column_name` exists in `dyncol_blob`. If yes, return `1`, otherwise return `0`. See dynamic columns for more information.

This page is licensed: CC BY-SA / Gnu FDL

COLUMN_GET

Syntax

```
COLUMN_GET(dyncol_blob, column_nr as type)
COLUMN_GET(dyncol_blob, column_name as type)
```

Description

Gets the value of a dynamic column by its name. If no column with the given name exists, `NULL` will be returned.

`column_name as type` requires that one specify the datatype of the dynamic column they are reading.

This may seem counter-intuitive: why would one need to specify which datatype they're retrieving? Can't the dynamic columns system figure the datatype from the data being stored?

The answer is: SQL is a statically-typed language. The SQL interpreter needs to know the datatypes of all expressions before the query is run (for example, when one is using prepared statements and runs `"select COLUMN_GET(...)"`, the prepared statement API requires the server to inform the client about the datatype of the column being read before the query is executed and the server can see what datatype the column actually has).

Lengths

Suppose running a query like this:

```
SELECT COLUMN_GET(BLOB, 'colname' AS CHAR) ...
```

Without specifying a maximum length (i.e. using `as CHAR`, not `as CHAR(n)`), MariaDB will report the maximum length of the result set column to be 16,777,216. This may cause excessive memory usage in some client libraries, because they try to pre-allocate a buffer of maximum result set width. To avoid this problem, use CHAR(n) whenever you're using COLUMN_GET in the select list.

See Dynamic Columns:Datatypes for more information about datatypes.

This page is licensed: CC BY-SA / Gnu FDL

COLUMN_JSON

Syntax

```
COLUMN_JSON(dyncol_blob)
```

Description

Returns a JSON representation of data in `dyncol_blob`. Can also be used to display nested columns. See dynamic columns for more information.

Example

```
SELECT item_name, COLUMN_JSON(dynamic_cols) FROM assets;
+-----------------+----------------------------------------+
| item_name       | COLUMN_JSON(dynamic_cols)              |
+-----------------+----------------------------------------+
| MariaDB T-shirt | {"size":"XL","color":"blue"}           |
| Thinkpad Laptop | {"color":"black","warranty":"3 years"} |
+-----------------+----------------------------------------+
```

Warning:

Limitation: `COLUMN_JSON` decodes nested dynamic columns at a nesting level of not more than 10 levels deep. Dynamic columns that are nested deeper than 10 levels are shown as `BINARY` string, without encoding.

This page is licensed: CC BY-SA / Gnu FDL

COLUMN_LIST

Syntax

```
COLUMN_LIST(dyncol_blob);
```

Description

Returns a comma-separated list of column names. The names are quoted with backticks.

See dynamic columns for more information.

This page is licensed: CC BY-SA / Gnu FDL

Galera Functions

See WSREP_LAST_SEEN_GTID.

Return the GTID of the most recent write transaction. This function helps determine the transaction ID to use for synchronization waiting.

See WSREP_LAST_WRITTEN_GTID.

Return the GTID of the client's last write. This function identifies the specific transaction ID generated by the current client's most recent write operation.

See WSREP_SYNC_WAIT_UPTO_GTID.

Wait for a specific GTID to be applied. This function blocks the client until the node has committed the transaction with the specified Global Transaction ID.

This page is licensed: CC BY-SA / Gnu FDL

WSREP_LAST_SEEN_GTID

Syntax

```
WSREP_LAST_SEEN_GTID()
```

Description

Returns the Global Transaction ID of the most recent write transaction observed by the client.

The result can be useful to determine the transaction to provide to WSREP_SYNC_WAIT_UPTO_GTID for waiting and unblocking purposes.

This page is licensed: CC BY-SA / Gnu FDL

WSREP_LAST_WRITTEN_GTID

Syntax

```
WSREP_LAST_WRITTEN_GTID()
```

Description

Returns the Global Transaction ID of the most recent write transaction performed by the client.

This page is licensed: CC BY-SA / Gnu FDL

WSREP_SYNC_WAIT_UPTO_GTID

Syntax

```
WSREP_SYNC_WAIT_UPTO_GTID(gtid[,timeout])
```

Description

Blocks the client until the transaction specified by the given Global Transaction ID is applied and committed by the node.

The optional *timeout* argument can be used to specify a block timeout in seconds. If not provided, the timeout will be indefinite.

Returns the node that applied and committed the Global Transaction ID, `ER_LOCAL_WAIT_TIMEOUT` if the function is timed out before this, or `ER_WRONG_ARGUMENTS` if the function is given an invalid GTID.

The result from WSREP_LAST_SEEN_GTID can be useful to determine the transaction to provide to `WSREP_SYNC_WAIT_UPTO_GTID` for waiting and unblocking purposes.

JSONPath Expressions

A number of JSON functions accept JSON Path expressions. MariaDB defines this path as follows:

JSON Path Syntax

```
path : ['lax'] '$' [step]*
```

The path starts with an optional *path mode*. At the moment, MariaDB supports only the "lax" mode, which is also the mode that is used when it is not explicitly specified.

The `$` symbol represents the context item. The search always starts from the context item; because of that, the path always starts with `$`.

Then, it is followed by zero or more steps, which select element(s) in the JSON document. A step may be one of the following:

- Object member selector.
- Array element selector.
- Wildcard selector.

Object Member Selector

To select member(s) in a JSON object, one can use one of the following:

- `.memberName` selects the value of the member with name memberName.
- `."memberName"` - the same as above but allows one to select a member with a name that's not a valid identifier (that is, has space, dot, and/or other characters).
- `.*` - selects the values of all members of the object.

If the current item is an array (instead of an object), nothing will be selected.

Array Element Selector

To select elements of an array, one can use one of the following:

- `[N]` selects element number N in the array. The elements are counted from zero.
- `[*]` selects all elements in the array.

If the current item is an object (instead of an array), nothing will be selected.

> **CURRENT**
>
> JSON path supports negative indexes in an array, 'last' keyword and range notation ('to' keyword) for accessing array elements. Negative indexes start from -1.
>
> - `[-N]` selects n th element from end.
> - `[last-N]` selects n th element from the last element.
> - `[M to N]` selects range of elements starting from index M to N.
>
> Example:

```
SET @json='{
            "A": [0,
                  [1, 2, 3],
                  [4, 5, 6],
                  "seven",
                   0.8,
                   true,
                   false,
                   "eleven",
                  [12, [13, 14], {"key1":"value1"},[15]],
                  true],
            "B": {"C": 1},
            "D": 2
           }';
SELECT JSON_EXTRACT(@json, '$.A[-8][1]');
+-------------------------------------------------+
| JSON_EXTRACT(@json, '$.A[-8][1]')               |
+-------------------------------------------------+
| 5                                               |
+-------------------------------------------------+

SELECT JSON_EXTRACT(@json, '$.A[last-7][1]');
+-----------------------------------------------+
| SELECT JSON_EXTRACT(@json, '$.A[last-7][1]'); |
+-----------------------------------------------+
| 5                                             |
+-----------------------------------------------+

SET @json= '[
             [1, {"key1": "value1"}, 3],
             [false, 5, 6],
             [7, 8, [9, {"key2": 2}, 11]],
             [15, 1.34, [14], ["string1", [16, {"key1":[1,2,3,[4,5,6]]}, 18]]],
             [19, 20],
             21, 22
            ]';

SELECT JSON_EXTRACT(@json, '$[0 to 3][2]');
+-----------------------------------------------+
| JSON_EXTRACT(@json, '$[0 to 3][2]')           |
+-----------------------------------------------+
| [3, 6, [9, {"key2": 2}, 11], [14]]            |
+-----------------------------------------------+
```

< 10.9

JSON path does **not** support negative indexes in an array.

This produces output for first index of eighth from last element of a two dimensional array.

Note: In range notation, when M > N (when M,N are greater than or equal to 0) or (size of array - M or size of array - N when M, N are less than 0), then it is treated as an impossible range and `NULL` is returned.

```
SET @json= '[1, 2, 3, 4, 5]';
SELECT JSON_EXTRACT(@json, '$[4 to 2]');
+----------------------------------+
| JSON_EXTRACT(@json, '$[4 to 2]') |
+----------------------------------+
| NULL                             |
+----------------------------------+
```

Wildcard

The wildcard step, `**`, recursively selects all child elements of the current element. Both array elements and object members are selected.

The wildcard step must not be the last step in the JSONPath expression. It must be followed by an array or object member selector step.

For example, this query selects all object members named `price` in the document:

```
SELECT json_extract(@json_doc, '$**.price');
```

This query, however, selects the second element in each of the arrays present in the document:

```
SELECT json_extract(@json_doc, '$**[2]');
```

Compatibility

MariaDB's JSONPath syntax supports a subset of JSON Path's definition in the SQL Standard. The most notable things not supported are the `strict` mode and filters.

MariaDB's JSONPath is close to MySQL's JSONPath. The wildcard step (`**`) is a non-standard extension that has the same meaning as in MySQL. The difference between MariaDB and MySQL's JSONPath is: MySQL doesn't allow one to specify the mode explicitly (but uses `lax` mode implicitly).

This page is licensed: CC BY-SA / Gnu FDL

Differences between JSON_QUERY and JSON_VALUE

The primary difference between the two functions is that *JSON_QUERY* returns an object or an array, while *JSON_VALUE* returns a scalar.

Take the following JSON document as an example:

```
SET @json='{ "x": [0,1], "y": "[0,1]", "z": "Monty" }';
```

Note that data member "x" is an array, and data members "y" and "z" are strings. The following examples demonstrate the differences between the two functions.

```
SELECT JSON_QUERY(@json,'$'), JSON_VALUE(@json,'$');
+-----------------------------------------+----------------------+
| JSON_QUERY(@json,'$')                   | JSON_VALUE(@json,'$') |
+-----------------------------------------+----------------------+
| { "x": [0,1], "y": "[0,1]", "z": "Monty" } | NULL                  |
+-----------------------------------------+----------------------+

SELECT JSON_QUERY(@json,'$.x'), JSON_VALUE(@json,'$.x');
+-------------------------+-------------------------+
| JSON_QUERY(@json,'$.x') | JSON_VALUE(@json,'$.x') |
+-------------------------+-------------------------+
| [0,1]                   | NULL                    |
+-------------------------+-------------------------+

SELECT JSON_QUERY(@json,'$.y'), JSON_VALUE(@json,'$.y');
+-------------------------+-------------------------+
| JSON_QUERY(@json,'$.y') | JSON_VALUE(@json,'$.y') |
+-------------------------+-------------------------+
| NULL                    | [0,1]                   |
+-------------------------+-------------------------+

SELECT JSON_QUERY(@json,'$.z'), JSON_VALUE(@json,'$.z');
+-------------------------+-------------------------+
| JSON_QUERY(@json,'$.z') | JSON_VALUE(@json,'$.z') |
+-------------------------+-------------------------+
| NULL                    | Monty                   |
+-------------------------+-------------------------+

SELECT JSON_QUERY(@json,'$.x[0]'), JSON_VALUE(@json,'$.x[0]');
+----------------------------+----------------------------+
| JSON_QUERY(@json,'$.x[0]') | JSON_VALUE(@json,'$.x[0]') |
+----------------------------+----------------------------+
| NULL                       | 0                          |
+----------------------------+----------------------------+
```

JSON Arrow Operators

Syntax

```
json_doc -> path
json_doc ->> path
```

Description

> **Note:**
>
> The `->` and `->>` operators were introduced in MariaDB 13.1.

The `->` and `->>` operators are shorthand for extracting a value from a JSON document by a JSONPath expression:

- `json_doc -> path` is equivalent to `JSON_EXTRACT(json_doc, path)`.
- `json_doc ->> path` is equivalent to `JSON_UNQUOTE ( JSON_EXTRACT (json_doc, path))`.

MariaDB supports these operators for compatibility with MySQL 5.7 and later, where they originated. Each operator builds the same expression as its equivalent function call and inherits the same `NULL` and error behavior. On the left, `json_doc` is any JSON expression — typically a column, a function result, or a JSON literal.

The two operators differ only in quoting:

- `->` returns the extracted value in its JSON representation, so a matched string keeps its surrounding double quotes (for example, `"Alice"`).
- `->>` additionally unquotes the result, returning the raw value (for example, `Alice`). Use `->>` when comparing against, sorting by, or displaying scalar values.

The following caveats apply and distinguish the operators from the underlying functions:

- **The path must be a string literal.** Unlike `JSON_EXTRACT()`, which accepts any expression as its path argument, the right-hand side of `->` and `->>` must be a literal string. A column, user variable (`data -> @path`), or placeholder (`data -> ?`) will not parse.
- **Chaining requires parentheses.** The operators do not chain directly; `col -> '$.a' -> '$.b'` is a syntax error. Wrap the intermediate result in parentheses instead: `(col -> '$.a') -> '$.b'`.
- **Precedence** is higher than the arithmetic and comparison operators, so `col ->> '$.age' = 30` is evaluated as `(col ->> '$.age') = 30`.

Examples

Before MariaDB 13.1, only the function form (`JSON_EXTRACT()` / `JSON_UNQUOTE(JSON_EXTRACT())`) worked in MariaDB; the `->` and `->>` operator form was accepted only by MySQL. As of MariaDB 13.1 both forms work, so queries written for MySQL 5.7+ port across unchanged.

The function form works in both MySQL and MariaDB:

```
SELECT JSON_EXTRACT('{"id":"1", "name":"Name"}', '$.name') `name`;
+--------+
| name   |
+--------+
| "Name" |
+--------+

SELECT JSON_UNQUOTE(JSON_EXTRACT('{"id":"1", "name":"Name"}', '$.name')) `name`;
+------+
| name |
+------+
| Name |
+------+
```

The equivalent operator form worked only in MySQL before MariaDB 13.1, and now works in MariaDB too:

```
SELECT '{"id":"1", "name":"Name"}'->'$.name' `name`;
+--------+
| name   |
+--------+
| "Name" |
+--------+

SELECT '{"id":"1", "name":"Name"}'->>'$.name' `name`;
+------+
| name |
+------+
| Name |
+------+
```

As with the function form, `->` keeps the JSON quoting (`"Name"`) while `->>` returns the unquoted value (`Name`).

The operators can be used anywhere an expression is allowed, such as in a `WHERE` clause:

```
CREATE TABLE t1 (id INT, data JSON);
INSERT INTO t1 VALUES (1, '{"id":"1", "name":"Name"}');

SELECT id FROM t1 WHERE data->>'$.name' = 'Name';
+------+
| id   |
+------+
|    1 |
+------+
```

See Also

- JSON_EXTRACT — the function `->` is shorthand for.
- JSON_UNQUOTE — combined with `JSON_EXTRACT`, the function `->>` is shorthand for.
- JSONPath Expressions — the path syntax used on the right-hand side.
- JSON_VALUE — related, but *not* equivalent: returns only scalar values, always unquoted.
- JSON_QUERY — related, but *not* equivalent: returns only objects or arrays.

JSON_ARRAY

Syntax

```
JSON_ARRAY([value[, value2] ...])
```

Description

Returns a JSON array containing the listed values. The list can be empty.

Example

```
SELECT Json_Array(56, 3.1416, 'My name is "Foo"', NULL);
+-------------------------------------------------+
| Json_Array(56, 3.1416, 'My name is "Foo"', NULL) |
+-------------------------------------------------+
| [56, 3.1416, "My name is \"Foo\"", null]         |
+-------------------------------------------------+
```

See also

- JSON_MAKE_ARRAY, the CONNECT storage engine function

This page is licensed: CC BY-SA / Gnu FDL

JSON_ARRAY_APPEND

Syntax

```
JSON_ARRAY_APPEND(json_doc, path, value[, path, value] ...)
```

Description

Appends values to the end of the specified arrays within a JSON document, returning the result, or `NULL` if any of the arguments are `NULL`.

Evaluation is performed from left to right, with the resulting document from the previous pair becoming the new value against which the next pair is evaluated.

If the `json_doc` is not a valid JSON document, or if any of the paths are not valid, or contain a `*` or `**` wildcard, an error is returned.

Examples

```
SET @json = '[1, 2, [3, 4]]';

SELECT JSON_ARRAY_APPEND(@json, '$[0]', 5)
+-------------------------------------+
| JSON_ARRAY_APPEND(@json, '$[0]', 5) |
+-------------------------------------+
| [[1, 5], 2, [3, 4]]                 |
+-------------------------------------+

SELECT JSON_ARRAY_APPEND(@json, '$[1]', 6);
+-------------------------------------+
| JSON_ARRAY_APPEND(@json, '$[1]', 6) |
+-------------------------------------+
| [1, [2, 6], [3, 4]]                 |
+-------------------------------------+

SELECT JSON_ARRAY_APPEND(@json, '$[1]', 6, '$[2]', 7);
+-----------------------------------------------+
| JSON_ARRAY_APPEND(@json, '$[1]', 6, '$[2]', 7) |
+-----------------------------------------------+
| [1, [2, 6], [3, 4, 7]]                        |
+-----------------------------------------------+

SELECT JSON_ARRAY_APPEND(@json, '$', 5);
+----------------------------------+
| JSON_ARRAY_APPEND(@json, '$', 5) |
+----------------------------------+
| [1, 2, [3, 4], 5]                |
+----------------------------------+

SET @json = '{"A": 1, "B": [2], "C": [3, 4]}';

SELECT JSON_ARRAY_APPEND(@json, '$.B', 5);
+-------------------------------------+
| JSON_ARRAY_APPEND(@json, '$.B', 5) |
+-------------------------------------+
| {"A": 1, "B": [2, 5], "C": [3, 4]} |
+-------------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

JSON_ARRAY_INSERT

Syntax

```
JSON_ARRAY_INSERT(json_doc, path, value[, path, value] ...)
```

Description

Inserts a value into a JSON document, returning the modified document, or `NULL` if any of the arguments are `NULL`.

Evaluation is performed from left to right, with the resulting document from the previous pair becoming the new value against which the next pair is evaluated.

If the `json_doc` is not a valid JSON document, or if any of the paths are not valid, or contain a `*` or `**` wildcard, an error is returned.

Examples

```
SET @json = '[1, 2, [3, 4]]';

SELECT JSON_ARRAY_INSERT(@json, '$[0]', 5);
+-----------------------------------+
| JSON_ARRAY_INSERT(@json, '$[0]', 5) |
+-----------------------------------+
| [5, 1, 2, [3, 4]]                 |
+-----------------------------------+

SELECT JSON_ARRAY_INSERT(@json, '$[1]', 6);
+-----------------------------------+
| JSON_ARRAY_INSERT(@json, '$[1]', 6) |
+-----------------------------------+
| [1, 6, 2, [3, 4]]                 |
+-----------------------------------+

SELECT JSON_ARRAY_INSERT(@json, '$[1]', 6, '$[2]', 7);
+-----------------------------------------------+
| JSON_ARRAY_INSERT(@json, '$[1]', 6, '$[2]', 7) |
+-----------------------------------------------+
| [1, 6, 7, 2, [3, 4]]                          |
+-----------------------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

JSON_ARRAY_INTERSECT

> **Note:**
>
> `JSON_ARRAY_INTERSECT` is available from MariaDB 11.2.

Syntax

```
JSON_ARRAY_INTERSECT(arr1, arr2)
```

Description

Finds intersection between two json arrays and returns an array of items found in both array.

Examples

```
SET @json1= '[1,2,3]';
SET @json2= '[1,2,4]';

SELECT json_array_intersect(@json1, @json2);
+-------------------------------------+
| json_array_intersect(@json1, @json2) |
+-------------------------------------+
| [1, 2]                              |
+-------------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

JSON_COMPACT

Syntax

```
JSON_COMPACT(json_doc)
```

Description

Removes all unnecessary spaces so the json document is as short as possible.

Example

```
SET @j = '{ "A": 1, "B": [2, 3]}';

SELECT JSON_COMPACT(@j), @j;
+-------------------+-----------------------+
| JSON_COMPACT(@j)  | @j                    |
+-------------------+-----------------------+
| {"A":1,"B":[2,3]} | { "A": 1, "B": [2, 3]} |
+-------------------+-----------------------+
```

See Also

- JSON video tutorial covering JSON_COMPACT.

This page is licensed: CC BY-SA / Gnu FDL

JSON_CONTAINS

Syntax

```
JSON_CONTAINS(json_doc, val[, path])
```

Description

Returns whether or not the specified value is found in the given JSON document or, optionally, at the specified path within the document. Returns `1` if it does, `0` if not and `NULL` if any of the arguments are null. An error occurs if the document or path is not valid, or contains the `*` or `**` wildcards.

Examples

```
SET @json = '{"A": 0, "B": {"C": 1}, "D": 2}';

SELECT JSON_CONTAINS(@json, '2', '$.A');
+---------------------------------+
| JSON_CONTAINS(@json, '2', '$.A') |
+---------------------------------+
|                               0 |
+---------------------------------+

SELECT JSON_CONTAINS(@json, '2', '$.D');
+---------------------------------+
| JSON_CONTAINS(@json, '2', '$.D') |
+---------------------------------+
|                               1 |
+---------------------------------+

SELECT JSON_CONTAINS(@json, '{"C": 1}', '$.A');
+---------------------------------------+
| JSON_CONTAINS(@json, '{"C": 1}', '$.A') |
+---------------------------------------+
|                                     0 |
+---------------------------------------+

SELECT JSON_CONTAINS(@json, '{"C": 1}', '$.B');
+---------------------------------------+
| JSON_CONTAINS(@json, '{"C": 1}', '$.B') |
+---------------------------------------+
|                                     1 |
+---------------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

JSON_CONTAINS_PATH

Syntax

```
JSON_CONTAINS_PATH(json_doc, return_arg, path[, path] ...)
```

Description

Indicates whether the given JSON document contains data at the specified path or paths. Returns `1` if it does, `0` if not and `NULL` if any of the arguments are null.

The *return_arg* can be `one` or `all`:

- `one` - Returns `1` if at least one path exists within the JSON document.
- `all` - Returns `1` only if all paths exist within the JSON document.

Examples

```
SET @json = '{"A": 1, "B": [2], "C": [3, 4]}';

SELECT JSON_CONTAINS_PATH(@json, 'one', '$.A', '$.D');
+-----------------------------------------------+
| JSON_CONTAINS_PATH(@json, 'one', '$.A', '$.D') |
+-----------------------------------------------+
|                                             1 |
+-----------------------------------------------+
1 row in set (0.00 sec)

SELECT JSON_CONTAINS_PATH(@json, 'all', '$.A', '$.D');
+-----------------------------------------------+
| JSON_CONTAINS_PATH(@json, 'all', '$.A', '$.D') |
+-----------------------------------------------+
|                                             0 |
+-----------------------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

JSON_DEPTH

Syntax

```
JSON_DEPTH(json_doc)
```

Description

Returns the maximum depth of the given JSON document, or `NULL` if the argument is null. An error occurs if the argument is an invalid JSON document.

- Scalar values or empty arrays or objects have a depth of 1.
- Arrays with only scalar values and objects with only scalar values for all keys have depth of 1.
- In all other cases, the depth can be 2 or greater.

> **12.2**
>
> There is no maximum depth level — it's unlimited.
>
> For more information, see this blog post.
>
> **< 12.2**
>
> The maximum depth is 32.

Examples

```
SELECT JSON_DEPTH('[]'), JSON_DEPTH('true'), JSON_DEPTH('{}');
+------------------+--------------------+------------------+
| JSON_DEPTH('[]') | JSON_DEPTH('true') | JSON_DEPTH('{}') |
+------------------+--------------------+------------------+
|                1 |                  1 |                1 |
+------------------+--------------------+------------------+

SELECT JSON_DEPTH('[1, 2, 3]'), JSON_DEPTH('[[], {}, []]');
+-------------------------+----------------------------+
| JSON_DEPTH('[1, 2, 3]') | JSON_DEPTH('[[], {}, []]') |
+-------------------------+----------------------------+
|                       2 |                          2 |
+-------------------------+----------------------------+

SELECT JSON_DEPTH('[1, 2, [3, 4, 5, 6], 7]');
+---------------------------------------+
| JSON_DEPTH('[1, 2, [3, 4, 5, 6], 7]') |
+---------------------------------------+
|                                     3 |
+---------------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

JSON_DETAILED

Syntax

```
JSON_DETAILED(json_doc[, tab_size])
JSON_PRETTY(json_doc[, tab_size])
```

Description

Represents JSON in the most understandable way emphasizing nested structures.

> **CURRENT**
>
> `JSON_PRETTY` is an alias for `JSON_DETAILED` .
>
> **< 10.10.3 / 10.9.5 / 10.8.7 / 10.7.8 / 10.6.12 / 10.5.19 / 10.4.28**
>
> `JSON_PRETTY` is **not** available as an alias for `JSON_DETAILED` .

Example

```
SET @j = '{ "A":1,"B":[2,3]}';

SELECT @j;
+--------------------+
| @j                 |
+--------------------+
| { "A":1,"B":[2,3]} |
+--------------------+

SELECT JSON_DETAILED(@j);
+------------------------------------------------------------+
| JSON_DETAILED(@j)                                          |
+------------------------------------------------------------+
| {
    "A": 1,
    "B":
    [
        2,
        3
    ]
} |
+------------------------------------------------------------+
```

See Also

- JSON video tutorial covering JSON_DETAILED.

JSON_EQUALS

> **Note:**
>
> `JSON_EQUALS` is available from MariaDB 10.7.

Syntax

```
JSON_EQUALS(json1, json2)
```

Description

Checks if there is equality between two json objects. Returns `1` if it there is, `0` if not, or NULL if any of the arguments are null.

Examples

```
SELECT JSON_EQUALS('{"a"   :[1, 2, 3],"b":[4]}', '{"b":[4],"a":[1, 2, 3.0]}');
+-------------------------------------------------------------------------+
| JSON_EQUALS('{"a"   :[1, 2, 3],"b":[4]}', '{"b":[4],"a":[1, 2, 3.0]}') |
+-------------------------------------------------------------------------+
|                                                                       1 |
+-------------------------------------------------------------------------+

SELECT JSON_EQUALS('{"a":[1, 2, 3]}', '{"a":[1, 2, 3.01]}');
+-----------------------------------------------------+
| JSON_EQUALS('{"a":[1, 2, 3]}', '{"a":[1, 2, 3.01]}') |
+-----------------------------------------------------+
|                                                   0 |
+-----------------------------------------------------+
```

See Also

- JSON_NORMALIZE

This page is licensed: CC BY-SA / Gnu FDL

JSON_EXISTS

Syntax

```
JSON_EXISTS(json_doc, json_path)
```

Description

Determines whether `json_doc` has an element pointed to by path `json_path`. Returns `1` if the element exists, `0` if not, or `NULL` if any of the inputs were `NULL`.

Examples

```
SELECT JSON_EXISTS('{"key1":"xxxx", "key2":[1, 2, 3]}', "$.key2");
+-----------------------------------------------------------+
| JSON_EXISTS('{"key1":"xxxx", "key2":[1, 2, 3]}', "$.key2") |
+-----------------------------------------------------------+
|                                                         1 |
+-----------------------------------------------------------+

SELECT JSON_EXISTS('{"key1":"xxxx", "key2":[1, 2, 3]}', "$.key3");
+-----------------------------------------------------------+
| JSON_EXISTS('{"key1":"xxxx", "key2":[1, 2, 3]}', "$.key3") |
+-----------------------------------------------------------+
|                                                         0 |
+-----------------------------------------------------------+

SELECT JSON_EXISTS('{"key1":"xxxx", "key2":[1, 2, 3]}', "$.key2[1]");
+--------------------------------------------------------------+
| JSON_EXISTS('{"key1":"xxxx", "key2":[1, 2, 3]}', "$.key2[1]") |
+--------------------------------------------------------------+
|                                                            1 |
+--------------------------------------------------------------+

SELECT JSON_EXISTS('{"key1":"xxxx", "key2":[1, 2, 3]}', "$.key2[10]");
+---------------------------------------------------------------+
| JSON_EXISTS('{"key1":"xxxx", "key2":[1, 2, 3]}', "$.key2[10]") |
+---------------------------------------------------------------+
|                                                             0 |
+---------------------------------------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

JSON_EXTRACT

Syntax

```
JSON_EXTRACT(json_doc, path[, path] ...)
```

Description

Extracts data from a JSON document. The extracted data is selected from the parts matching the path arguments. Returns all matched values; either as a single matched value, or, if the arguments could return multiple values, a result autowrapped as an array in the matching order.

Returns `NULL` if no paths match or if any of the arguments are `NULL`.

An error occurs if any path argument is not a valid path, or if the json_doc argument is not a valid JSON document.

The path expression be a JSONPath expression as supported by MariaDB

Examples

```
SET @json = '[1, 2, [3, 4]]';

SELECT JSON_EXTRACT(@json, '$[1]');
+----------------------------+
| JSON_EXTRACT(@json, '$[1]') |
+----------------------------+
| 2                          |
+----------------------------+

SELECT JSON_EXTRACT(@json, '$[2]');
+----------------------------+
| JSON_EXTRACT(@json, '$[2]') |
+----------------------------+
| [3, 4]                     |
+----------------------------+

SELECT JSON_EXTRACT(@json, '$[2][1]');
+-------------------------------+
| JSON_EXTRACT(@json, '$[2][1]') |
+-------------------------------+
| 4                             |
+-------------------------------+
```

See Also

- JSON Arrow Operators — the `->` operator is shorthand for `JSON_EXTRACT()`.
- JSON video tutorial covering JSON_EXTRACT.

JSON_INSERT

Syntax

```
JSON_INSERT(json_doc, path, val[, path, val] ...)
```

Description

Inserts data into a JSON document, returning the resulting document or `NULL` if either of the *json_doc* or *path* arguments are null.

An error occurs if the JSON document is invalid, or if any of the paths are invalid or contain a `*` or `**` wildcard.

JSON_INSERT can only insert data, while JSON_REPLACE can only update. JSON_SET can update or insert data.

Examples

```
SET @json = '{ "A": 0, "B": [1, 2]}';

SELECT JSON_INSERT(@json, '$.C', '[3, 4]');
+-------------------------------------+
| JSON_INSERT(@json, '$.C', '[3, 4]')  |
+-------------------------------------+
| { "A": 0, "B": [1, 2], "C":"[3, 4]"} |
+-------------------------------------+
```

See Also

- JSON video tutorial covering JSON_INSERT.

This page is licensed: CC BY-SA / Gnu FDL

JSON_KEY_VALUE

> **Note:**
>
> JSON_KEY_VALUE is available from MariaDB 11.2.

Syntax

```
JSON_KEY_VALUE(obj, json_path)
```

Description

`JSON_KEY_VALUE` extracts key/value pairs from a JSON object. The JSON path parameter is used to only return key/value pairs for matching JSON objects.

Example

```
SELECT JSON_KEY_VALUE('[[1, {"key1":"val1", "key2":"val2"}, 3], 2, 3]', '$[0][1]');
+-------------------------------------------------------------------------+
| JSON_KEY_VALUE('[[1, {"key1":"val1", "key2":"val2"}, 3], 2, 3]', '$[0][1]') |
+-------------------------------------------------------------------------+
| [{"key": "key1", "value": "val1"}, {"key": "key2", "value": "val2"}]        |
+-------------------------------------------------------------------------+
```

`JSON_KEY_VALUE()` can be used as an argument to JSON_TABLE(), which allows adding the key to a result set.

```
SELECT jt.* FROM JSON_TABLE(
JSON_KEY_VALUE('[[1, {"key1":"val1", "key2":"val2"}, 3], 2, 3]', '$[0][1]'),'$[*]'
COLUMNS (
k VARCHAR(20) PATH '$.key',
v VARCHAR(20) PATH '$.value',
id FOR ORDINALITY )) AS jt;
+------+------+------+
| k    | v    | id   |
+------+------+------+
| key1 | val1 |    1 |
| key2 | val2 |    2 |
+------+------+------+
```

This page is licensed: CC BY-SA / Gnu FDL

JSON_KEYS

Syntax

```
JSON_KEYS(json_doc[, path])
```

Description

Returns the keys as a JSON array from the top-level value of a JSON object or, if the optional path argument is provided, the top-level keys from the path.

Excludes keys from nested sub-objects in the top level value. The resulting array will be empty if the selected object is empty.

Returns `NULL` if any of the arguments are null, a given path does not locate an object, or if the json_doc argument is not an object.

An error will occur if JSON document is invalid, the path is invalid or if the path contains a `*` or `**` wildcard.

Examples

```
SELECT JSON_KEYS('{"A": 1, "B": {"C": 2}}');
+--------------------------------------+
| JSON_KEYS('{"A": 1, "B": {"C": 2}}') |
+--------------------------------------+
| ["A", "B"]                           |
+--------------------------------------+

SELECT JSON_KEYS('{"A": 1, "B": 2, "C": {"D": 3}}', '$.C');
+-----------------------------------------------------+
| JSON_KEYS('{"A": 1, "B": 2, "C": {"D": 3}}', '$.C') |
+-----------------------------------------------------+
| ["D"]                                               |
+-----------------------------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

JSON_LENGTH

Syntax

```
JSON_LENGTH(json_doc[, path])
```

Description

Returns the length of a JSON document, or, if the optional path argument is given, the length of the value within the document specified by the path.

Returns `NULL` if any of the arguments argument are null or the path argument does not identify a value in the document.

An error occurs if the JSON document is invalid, the path is invalid or if the path contains a `*` or `**` wildcard.

Length will be determined as follow:

- A scalar's length is always 1.
- If an array, the number of elements in the array.
- If an object, the number of members in the object.

The length of nested arrays or objects are not counted.

Examples

```

```

This page is licensed: CC BY-SA / Gnu FDL

JSON_LOOSE

Syntax

```
JSON_LOOSE(json_doc)
```

Description

Adds spaces to a JSON document to make it look more readable.

Example

```
SET @j = '{ "A":1,"B":[2,3]}';

SELECT JSON_LOOSE(@j), @j;
+----------------------+--------------------+
| JSON_LOOSE(@j)       | @j                 |
+----------------------+--------------------+
| {"A": 1, "B": [2, 3]} | { "A":1,"B":[2,3]} |
+----------------------+--------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

JSON_MERGE

Syntax

```
JSON_MERGE(json_doc, json_doc[, json_doc] ...)
```

Description

Merges the given JSON documents.

Returns the merged result, or `NULL` if any argument is `NULL`.

An error occurs if any of the arguments are not valid JSON documents.

> **Warning:**
>
> `JSON_MERGE` is deprecated. JSON_MERGE_PATCH is an RFC 7396-compliant replacement, and JSON_MERGE_PRESERVE is a synonym.

Example

```
SET @json1 = '[1, 2]';
SET @json2 = '[3, 4]';

SELECT JSON_MERGE(@json1,@json2);
+---------------------------+
| JSON_MERGE(@json1,@json2) |
+---------------------------+
| [1, 2, 3, 4]              |
+---------------------------+
```

See Also

- JSON_MERGE_PATCH
- JSON_MERGE_PRESERVE

This page is licensed: CC BY-SA / Gnu FDL

JSON_MERGE_PATCH

Syntax

```
JSON_MERGE_PATCH(json_doc, json_doc[, json_doc] ...)
```

Description

Merges the given JSON documents, returning the merged result, or `NULL` if any argument is `NULL`.

`JSON_MERGE_PATCH` is an RFC 7396-compliant replacement for JSON_MERGE, which is deprecated.

Unlike JSON_MERGE_PRESERVE, members with duplicate keys are not preserved.

Example

```
SET @json1 = '[1, 2]';
SET @json2 = '[2, 3]';
SELECT JSON_MERGE_PATCH(@json1,@json2),JSON_MERGE_PRESERVE(@json1,@json2);
+---------------------------------+-----------------------------------+
| JSON_MERGE_PATCH(@json1,@json2) | JSON_MERGE_PRESERVE(@json1,@json2) |
+---------------------------------+-----------------------------------+
| [2, 3]                          | [1, 2, 2, 3]                      |
+---------------------------------+-----------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

JSON_MERGE_PRESERVE

Syntax

```
JSON_MERGE_PRESERVE(json_doc, json_doc[, json_doc] ...)
```

Description

Merges the given JSON documents, returning the merged result, or `NULL` if any argument is `NULL`.

`JSON_MERGE_PRESERVE` is a synonym for JSON_MERGE, which has been deprecated.

Unlike JSON_MERGE_PATCH, members with duplicate keys are preserved.

Example

```
SET @json1 = '[1, 2]';
SET @json2 = '[2, 3]';
SELECT JSON_MERGE_PATCH(@json1,@json2),JSON_MERGE_PRESERVE(@json1,@json2);
+---------------------------------+-----------------------------------+
| JSON_MERGE_PATCH(@json1,@json2) | JSON_MERGE_PRESERVE(@json1,@json2) |
+---------------------------------+-----------------------------------+
| [2, 3]                          | [1, 2, 2, 3]                      |
+---------------------------------+-----------------------------------+
```

See Also

- JSON_MERGE_PATCH

This page is licensed: CC BY-SA / Gnu FDL

JSON_NORMALIZE

> **Note:**
>
> `JSON_NORMALIZE` is available from MariaDB 10.7.

Syntax

```
JSON_NORMALIZE(json)
```

Description

Recursively sorts keys and removes spaces, allowing comparison of json documents for equality.

Examples

We may wish our application to use the database to enforce a unique constraint on the JSON contents, and we can do so using the `JSON_NORMALIZE` function in combination with a unique key.

For example, if we have a table with a JSON column:

```
CREATE TABLE t1 (
 id BIGINT UNSIGNED NOT NULL AUTO_INCREMENT,
 val JSON,
 /* other columns here */
 PRIMARY KEY (id)
);
```

Add a unique constraint using JSON_NORMALIZE like this:

```
ALTER TABLE t1
   ADD COLUMN jnorm JSON AS (JSON_NORMALIZE(val)) VIRTUAL,
   ADD UNIQUE KEY (jnorm);
```

We can test this by first inserting a row as normal:

```
INSERT INTO t1 (val) VALUES ('{"name":"alice","color":"blue"}');
```

And then seeing what happens with a different string which would produce the same JSON object:

```
INSERT INTO t1 (val) VALUES ('{ "color": "blue", "name": "alice" }');
ERROR 1062 (23000): Duplicate entry '{"color":"blue","name":"alice"}' for key 'jnorm'
```

See Also

- JSON_EQUALS

This page is licensed: CC BY-SA / Gnu FDL

JSON_OBJECT

Syntax

```
JSON_OBJECT([key, value[, key, value] ...])
```

Description

Returns a JSON object containing the given key/value pairs. The key/value list can be empty.

An error will occur if there are an odd number of arguments, or any key name is `NULL`.

Example

```
SELECT JSON_OBJECT("id", 1, "name", "Monty");
+---------------------------------------+
| JSON_OBJECT("id", 1, "name", "Monty") |
+---------------------------------------+
| {"id": 1, "name": "Monty"}            |
+---------------------------------------+
```

- JSON_MAKE_OBJECT, the CONNECT storage engine function

This page is licensed: CC BY-SA / Gnu FDL

JSON_OBJECT_FILTER_KEYS

> **Note:**
>
> JSON_OBJECT_FILTER_KEYS is available from MariaDB 11.2.

Syntax

```
JSON_OBJECT_FILTER_KEYS(obj, array_keys)
```

Description

`JSON_OBJECT_FILTER_KEYS` returns a JSON object with keys from the object that are also present in the array as string. It is used when one wants to get key-value pair such that the keys are common but the values may not be common.

Example

```
SET @obj1= '{ "a": 1, "b": 2, "c": 3}';
SET @obj2= '{"b" : 10, "c": 20, "d": 30}';
SELECT JSON_OBJECT_FILTER_KEYS (@obj1, JSON_ARRAY_INTERSECT(JSON_KEYS(@obj1), JSON_KEYS(@obj2)));
+-----------------------------------------------------------------------------------------+
| JSON_OBJECT_FILTER_KEYS (@obj1, JSON_ARRAY_INTERSECT(JSON_KEYS(@obj1), JSON_KEYS(@obj2))) |
+-----------------------------------------------------------------------------------------+
| {"b": 2, "c": 3}                                                                        |
+-----------------------------------------------------------------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

JSON_OBJECT_TO_ARRAY

> **Note:**
>
> JSON_OBJECT_TO_ARRAY is available from MariaDB 11.2.

Syntax

```
JSON_OBJECT_TO_ARRAY(Obj)
```

Description

It is used to convert all JSON objects found in a JSON document to JSON arrays where each item in the outer array represents a single key-value pair from the object. It is used when we want not just common keys, but also common values. It can be used in conjunction with `JSON_ARRAY_INTERSECT()`.

Examples

```
SET @obj1= '{ "a": [1, 2, 3], "b": { "key1":"val1", "key2": {"key3":"val3"} }}';

SELECT JSON_OBJECT_TO_ARRAY(@obj1);
+-----------------------------------------------------------------------+
| JSON_OBJECT_TO_ARRAY(@obj1)                                           |
+-----------------------------------------------------------------------+
| [["a", [1, 2, 3]], ["b", {"key1": "val1", "key2": {"key3": "val3"}}]] |
+-----------------------------------------------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

JSON_OVERLAPS

> **Note:**
>
> `JSON_OVERLAPS` is available from MariaDB 10.9.

Syntax

```
JSON_OVERLAPS(json_doc1, json_doc2)
```

Description

`JSON_OVERLAPS()` compares two json documents and returns true if they have at least one common key-value pair between two objects, array element common between two arrays, or array element common with scalar if one of the arguments is a scalar and other is an array. If two json documents are scalars, it returns true if they have same type and value.

If none of the above conditions are satisfied then it returns false.

Examples

```
SELECT JSON_OVERLAPS('false', 'false');
+---------------------------------+
| JSON_OVERLAPS('false', 'false') |
+---------------------------------+
| 1                               |
+---------------------------------+

SELECT JSON_OVERLAPS('true', '["abc", 1, 2, true, false]');
+---------------------------------------------------+
| JSON_OVERLAPS('true','["abc", 1, 2, true, false]') |
+---------------------------------------------------+
| 1                                                 |
+---------------------------------------------------+

SELECT JSON_OVERLAPS('{"A": 1, "B": {"C":2}}', '{"A": 2, "B": {"C":2}}') AS is_overlap;
+---------------------+
| is_overlap          |
+---------------------+
| 1                   |
+---------------------+
```

Partial match is considered as no-match.

Examples

```
SELECT JSON_OVERLAPS('[1, 2, true, false, null]', '[3, 4, [1]]') AS is_overlap;
+--------------------- +
| is_overlap           |
+----------------------+
| 0                    |
+----------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

JSON_PRETTY

> **Note:**
>
> JSON_PRETTY is available from MariaDB 10.10.3, 10.9.5, 10.8.7, 10.7.8, 10.6.12, 10.5.19, and 10.4.28.

`JSON_PRETTY` is an alias for JSON_DETAILED.

This page is licensed: CC BY-SA / Gnu FDL

JSON_QUERY

Syntax

```
JSON_QUERY(json_doc, path)
```

Description

Given a JSON document, returns an object or array specified by the path. Returns `NULL` if not given a valid JSON document, or if there is no match.

Examples

```
SELECT json_query('{"key1":{"a":1, "b":[1,2]}}', '$.key1');
+-----------------------------------------------------+
| json_query('{"key1":{"a":1, "b":[1,2]}}', '$.key1') |
+-----------------------------------------------------+
| {"a":1, "b":[1,2]}                                  |
+-----------------------------------------------------+

SELECT json_query('{"key1":123, "key1": [1,2,3]}', '$.key1');
+-----------------------------------------------------+
| json_query('{"key1":123, "key1": [1,2,3]}', '$.key1') |
+-----------------------------------------------------+
| [1,2,3]                                             |
+-----------------------------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

JSON_QUOTE

Syntax

```
JSON_QUOTE(json_value)
```

Description

Quotes a string as a JSON value, usually for producing valid JSON string literals for inclusion in JSON documents. Wraps the string with double quote characters and escapes interior quotes and other special characters, returning a

utf8mb4 string.

Returns `NULL` if the argument is `NULL`.

Examples

```
SELECT JSON_QUOTE('A'), JSON_QUOTE("B"), JSON_QUOTE('"C"');
+-----------------+-----------------+------------------+
| JSON_QUOTE('A') | JSON_QUOTE("B") | JSON_QUOTE('"C"') |
+-----------------+-----------------+------------------+
| "A"             | "B"             | "\"C\""          |
+-----------------+-----------------+------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

JSON_REMOVE

Syntax

```
JSON_REMOVE(json_doc, path[, path] ...)
```

Description

Removes data from a JSON document returning the result, or `NULL` if any of the arguments are null. If the element does not exist in the document, no changes are made.

The function returns `NULL` and throws a warning if the JSON document is invalid, the path is invalid, contains a range, or contains a `*` or `**` wildcard.

Path arguments are evaluated from left to right, with the result from the earlier evaluation being used as the value for the next.

Examples

```
SELECT JSON_REMOVE('{"A": 1, "B": 2, "C": {"D": 3}}', '$.C');
+-----------------------------------------------------+
| JSON_REMOVE('{"A": 1, "B": 2, "C": {"D": 3}}', '$.C') |
+-----------------------------------------------------+
| {"A": 1, "B": 2}                                    |
+-----------------------------------------------------+

SELECT JSON_REMOVE('["A", "B", ["C", "D"], "E"]', '$[1]');
+--------------------------------------------------+
| JSON_REMOVE('["A", "B", ["C", "D"], "E"]', '$[1]') |
+--------------------------------------------------+
| ["A", ["C", "D"], "E"]                           |
+--------------------------------------------------+
```

See Also

- JSON video tutorial covering JSON_REMOVE.

JSON_REPLACE

Syntax

```
JSON_REPLACE(json_doc, path, val[, path, val] ...)
```

Description

Replaces existing values in a JSON document, returning the result, or `NULL` if any of the arguments are `NULL`.

An error will occur if the JSON document is invalid, the path is invalid or if the path contains a `*` or `**` wildcard.

Paths and values are evaluated from left to right, with the result from the earlier evaluation being used as the value for the next.

JSON_REPLACE can only update data, while JSON_INSERT can only insert. JSON_SET can update or insert data.

Examples

```
SELECT JSON_REPLACE('{ "A": 1, "B": [2, 3]}', '$.B[1]', 4);
+-----------------------------------------------------+
| JSON_REPLACE('{ "A": 1, "B": [2, 3]}', '$.B[1]', 4) |
+-----------------------------------------------------+
| { "A": 1, "B": [2, 4]}                              |
+-----------------------------------------------------+
```

JSON_SCHEMA_VALID

> **Note:**
>
> `JSON_SCHEMA_VALID` is available from MariaDB 11.1.

Syntax

```
JSON_SCHEMA_VALID(schema, json);
```

Description

`JSON_SCHEMA_VALID` allows MariaDB to support JSON schema validation. If a given json is valid against a schema it returns true. When JSON does not validate against the schema, it does not return a message about which keyword it failed against and only returns false.

The function supports JSON Schema Draft 2020 with a few exceptions:

- External resources are not supported.
- Hyper schema keywords are not supported.
- Formats like date, email etc are treated as annotations.

Examples

To create validation rules for json field, do this:

```
CREATE TABLE obj_table(val_obj JSON CHECK(JSON_SCHEMA_VALID('{
  "type":"object",
    "properties": {
      "number1":{
        "type":"number",
        "maximum":5,
        "const":4
      },
      "string1":{
        "type":"string",
        "maxLength":5,
        "minLength":3
      },
    "object1":{
      "type":"object",
       "properties":{
         "key1": {"type":"string"},
         "key2":{"type":"array"},
         "key3":{"type":"number", "minimum":3}
       },
       "dependentRequired": { "key1":["key3"] }
     }
  },
  "required":["number1","object1"]
  }', val_obj)));

INSERT INTO obj_table VALUES(
  '{"number1":4, "string1":"abcd",
  "object1":{"key1":"val1", "key2":[1,2,3, "string1"], "key3":4}}'
);

INSERT INTO obj_table VALUES(
  '{"number1":3, "string1":"abcd",
  "object1":{"key1":"val1", "key2":[1,2,3, "string1"], "key3":4}}'
);
ERROR 4025 (23000): CONSTRAINT `obj_table.val_obj` failed for `test`.`obj_table`

SELECT * FROM obj_table;
+-----------------------------------------------------------------------------------------------------+
| val_obj                                                                                             |
+-----------------------------------------------------------------------------------------------------+
| {"number1":4, "string1":"abcd", "object1":{"key1":"val1", "key2":[1,2,3, "string1"], "key3":4}} |
+-----------------------------------------------------------------------------------------------------+

SET @schema= '{
  "properties" : {
    "number1":{ "maximum":10 },
    "string1" : { "maxLength": 3}
  }
}';

SELECT JSON_SCHEMA_VALID(@schema, '{ "number1":25, "string1":"ab" }');
+-------------------------------------------------------------------+
| JSON_SCHEMA_VALID(@schema, '{ "number1":25, "string1":"ab" }') |
+-------------------------------------------------------------------+
|                                                                 0 |
+-------------------------------------------------------------------+

SELECT JSON_SCHEMA_VALID(@schema, '{ "number1":10, "string1":"ab" }');
+-------------------------------------------------------------------+
| JSON_SCHEMA_VALID(@schema, '{ "number1":10, "string1":"ab" }') |
+-------------------------------------------------------------------+
|                                                                 1 |
+-------------------------------------------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

JSON_SEARCH

Syntax

```
JSON_SEARCH(json_doc, return_arg, search_str[, escape_char[, path] ...])
```

Description

Returns the path to the given string within a JSON document, or `NULL` if any of *json_doc*, *search_str* or a path argument is `NULL`; if the search string is not found, or if no path exists within the document.

A warning will occur if the JSON document is not valid, any of the path arguments are not valid, if *return_arg* is neither *one* nor *all*, or if the escape character is not a constant. `NULL` will be returned.

return_arg can be one of two values:

- `'one`: Terminates after finding the first match, so will return one path string. If there is more than one match, it is undefined which is considered first.
- `all`: Returns all matching path strings, without duplicates. Multiple strings are autowrapped as an array. The order is undefined.

Examples

```
SET @json = '["A", [{"B": "1"}], {"C":"AB"}, {"D":"BC"}]';

SELECT JSON_SEARCH(@json, 'one', 'AB');
+---------------------------------+
| JSON_SEARCH(@json, 'one', 'AB') |
+---------------------------------+
| "$[2].C"                        |
+---------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

JSON_SET

Syntax

```
JSON_SET(json_doc, path, val[, path, val] ...)
```

Description

Updates or inserts data into a JSON document, returning the result, or `NULL` if any of the arguments are `NULL` or the optional path fails to find an object.

An error will occur if the JSON document is invalid, the path is invalid or if the path contains a `*` or a wildcard**.**

`JSON_SET` can update or insert data, while JSON_REPLACE can only update, and JSON_INSERT only insert.

Examples

```
SELECT JSON_SET(Priv, '$.locked', 'true') FROM mysql.global_priv
```

This page is licensed: CC BY-SA / Gnu FDL

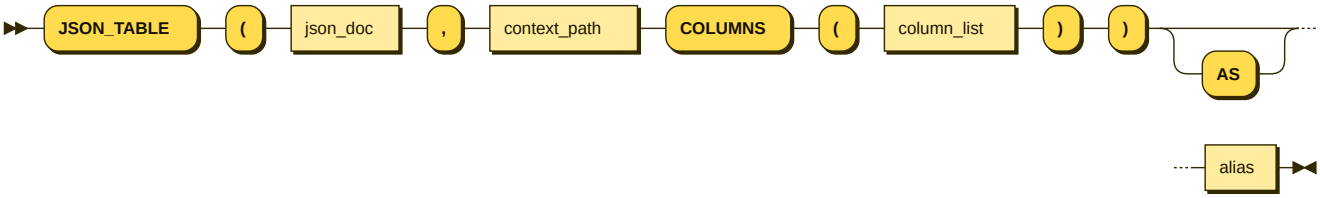
JSON_TABLE

> **Note:**
>
> `JSON_TABLE` is available from MariaDB 10.6.

`JSON_TABLE` is a table function that converts JSON data into a relational form.

Syntax

```
JSON_TABLE(json_doc,
          context_path COLUMNS (column_list)
) [AS] alias
```



Railroad diagram of JSON_TABLE — equivalent to the BNF above

```
column_list:
    column[, column][, ...]
```

```
column:
    name FOR ORDINALITY
    |  name type PATH path_str [on_empty] [on_error]
    |  name type FORMAT JSON PATH path_str [on_empty] [on_error]
    |  name type EXISTS PATH path_str
    |  NESTED PATH path_str COLUMNS (column_list)
```

```
on_empty:
    {NULL | DEFAULT string | ERROR} ON EMPTY
```

```
on_error:
    {NULL | DEFAULT string | ERROR} ON ERROR
```

Description

`JSON_TABLE` can be used in contexts where a table reference can be used; in the `FROM` clause of a SELECT statement, and in multi-table UPDATE/DELETE statements.

`json_doc` is the JSON document to extract data from. In the simplest case, it is a string literal containing JSON. In more complex cases it can be an arbitrary expression returning JSON. The expression may have references to columns of other tables. However, one can only refer to tables that precede this JSON_TABLE invocation. For RIGHT JOIN, it is assumed that its outer side precedes the inner. All tables in outer selects are also considered preceding.

`context_path` is a JSON Path expression pointing to a collection of nodes in `json_doc` that will be used as the source of rows.

The `COLUMNS` clause declares the names and types of the columns that JSON_TABLE returns, as well as how the values of the columns are produced.

Column Definitions

The following types of columns are supported:

Path Columns

```
name type PATH path_str [on_empty] [on_error]
```

Locates the JSON node pointed to by `path_str` and returns its value. The path_str is evaluated using the current row source node as the context node.

```
SET @json='
[
  {"name":"Laptop", "color":"black", "price":"1000"},
  {"name":"Jeans",  "color":"blue"}
]';

SELECT * FROM json_table(@json, '$[*]'
  COLUMNS(
   name  VARCHAR(10) path '$.name',
   color VARCHAR(10) path '$.color',
   price DECIMAL(8,2) path '$.price' )
) AS jt;
+--------+-------+---------+
| name   | color | price   |
+--------+-------+---------+
| Laptop | black | 1000.00 |
| Jeans  | blue  |    NULL |
+--------+-------+---------+
```

The `on_empty` and `on_error` clauses specify the actions to be performed when the value was not found or there was an error condition. See the `ON EMPTY` and `ON ERROR` clauses section for details.

FORMAT JSON Columns

> **Note:**
>
> `FORMAT JSON` columns are available from MariaDB 13.1.1.

```
name type FORMAT JSON PATH path_str [on_empty] [on_error]
```

Like a path column, but returns the JSON value located by `path_str` as-is, serialized to text — including arrays and objects, not only scalar values. This is useful for pulling a nested array or object into a single column without expanding it into multiple rows with `NESTED PATH`.

The column must be declared with a string type, such as VARCHAR or TEXT. Using `FORMAT JSON` with a non-string type raises an error.

```
SET @json='
[
  {"name":"Jeans",   "sizes": [32, 34, 36]},
  {"name":"T-Shirt", "sizes":["Medium", "Large"]},
  {"name":"Cellphone"}
]';

SELECT * FROM JSON_TABLE(@json, '$[*]'
  COLUMNS(
    name  VARCHAR(10)  PATH '$.name',
    sizes VARCHAR(100) FORMAT JSON PATH '$.sizes'
  )
) AS jt;
+-----------+---------------------+
| name      | sizes               |
+-----------+---------------------+
| Jeans     | [32, 34, 36]        |
| T-Shirt   | ["Medium", "Large"] |
| Cellphone | NULL                |
+-----------+---------------------+
```

Without `FORMAT JSON`, a path column returns only scalar values; locating an array or object instead triggers the `ON ERROR` behavior (`NULL` by default). A column declared with the JSON type applies `FORMAT JSON` implicitly — see Extracting a Subdocument into a Column.

ORDINALITY Columns

```
name FOR ORDINALITY
```

Counts the rows, starting from 1.

Example:

```
set @json='
[
  {"name":"Laptop", "color":"black"},
  {"name":"Jeans",  "color":"blue"}
]';

select * from json_table(@json, '$[*]'
  columns(
   id for ordinality,
   name  varchar(10) path '$.name')
) as jt;
+------+--------+
| id   | name   |
+------+--------+
|    1 | Laptop |
|    2 | Jeans  |
+------+--------+
```

EXISTS PATH Columns

```
name type EXISTS PATH path_str
```

Checks whether the node pointed to by `value_path` exists. The `value_path` is evaluated using the current row source node as the context node.

```
set @json='
[
  {"name":"Laptop", "color":"black", "price":1000},
  {"name":"Jeans",  "color":"blue"}
]';

select * from json_table(@json, '$[*]'
  columns(
   name  varchar(10) path '$.name',
   has_price integer exists path '$.price')
) as jt;
+--------+-----------+
| name   | has_price |
+--------+-----------+
| Laptop |         1 |
| Jeans  |         0 |
+--------+-----------+
```

NESTED PATHs

NESTED PATH converts nested JSON structures into multiple rows.

```
NESTED PATH path COLUMNS (column_list)
```

It finds the sequence of JSON nodes pointed to by `path` and uses it to produce rows. For each found node, a row is generated with column values as specified by the NESTED PATH's COLUMNS clause. If `path` finds no nodes, only one row is generated with all columns having NULL values.

For example, consider a JSON document that contains an array of items, and each item, in turn, is expected to have an array of its available sizes:

```
SET @json='
[
  {"name":"Jeans",  "sizes": [32, 34, 36]},
  {"name":"T-Shirt", "sizes":["Medium", "Large"]},
  {"name":"Cellphone"}
]';
```

NESTED PATH allows one to produce a separate row for each size each item has:

```
select * from json_table(@json, '$[*]'
  columns(
    name  varchar(10) path '$.name',
    nested path '$.sizes[*]' columns (
      size varchar(32) path '$'
    )
  )
) as jt;
+-----------+--------+
| name      | size   |
+-----------+--------+
| Jeans     | 32     |
| Jeans     | 34     |
| Jeans     | 36     |
| T-Shirt   | Medium |
| T-Shirt   | Large  |
| Cellphone | NULL   |
+-----------+--------+
```

`NESTED PATH` clauses can be nested within one another. They can also be located next to each other. In that case, the nested path clauses will produce records one at a time. The ones that are not producing records will have all columns set to `NULL`.

Example:

```
set @json='
[
  {"name":"Jeans",  "sizes": [32, 34, 36], "colors":["black", "blue"]}
]';

select * from json_table(@json, '$[*]'
  columns(
    name  varchar(10) path '$.name',
    nested path '$.sizes[*]' columns (
      size varchar(32) path '$'
    ),
    nested path '$.colors[*]' columns (
      color varchar(32) path '$'
    )
  )
) as jt;

+-------+------+-------+
| name  | size | color |
+-------+------+-------+
| Jeans | 32   | NULL  |
| Jeans | 34   | NULL  |
| Jeans | 36   | NULL  |
| Jeans | NULL | black |
| Jeans | NULL | blue  |
+-------+------+-------+
```

ON EMPTY and ON ERROR Clauses

The ON EMPTY clause specifies what will be done when the element specified by the search path is missing in the JSON document.

```
on_empty:
    {NULL | DEFAULT string | ERROR} ON EMPTY
```

When `ON EMPTY` clause is not present, `NULL ON EMPTY` is implied.

```
on_error:
    {NULL | DEFAULT string | ERROR} ON ERROR
```

The ON ERROR clause specifies what should be done if a JSON structure error occurs when trying to extract the value pointed to by the path expression. A JSON structure error here occurs only when one attempts to convert a JSON non-scalar (array or object) into a scalar value. When the `ON ERROR` clause is not present, `NULL ON ERROR` is implied.

Note: A datatype conversion error (e.g. attempt to store a non-integer value into an integer field, or a varchar column being truncated) is not considered a JSON error and so will not trigger the `ON ERROR` behavior. It will produce warnings, in the same way as CAST(value AS datatype) would.

Replication

In the current code, evaluation of `JSON_TABLE` is deterministic, that is, for a given input string `JSON_TABLE` will always produce the same set of rows in the same order. However, one can think of JSON documents that one can consider identical which will produce different output. In order to be future-proof and withstand changes like

- sorting JSON object members by name (like MySQL does);
- changing the way duplicate object members are handled the function is marked as unsafe for statement-based replication.

Extracting a Subdocument into a Column

CURRENT

```
SELECT * FROM JSON_TABLE('{"foo": [1,2,3,4]}','$' columns( jscol json path '$.foo') ) AS T;
+-----------+
| jscol     |
+-----------+
| [1,2,3,4] |
+-----------+
```

< 10.6.9

`JSON_TABLE` does not allow to extract a JSON "subdocument" into a JSON column.

```
SELECT * FROM JSON_TABLE('{"foo": [1,2,3,4]}','$' columns( jscol json path '$.foo') ) AS T;
+-------+
| jscol |
+-------+
| NULL  |
+-------+
```

See Also

- JSON Support (video)

This page is licensed: CC BY-SA / Gnu FDL

JSON_TYPE

Syntax

```
JSON_TYPE(json_val)
```

Description

Returns the type of a JSON value (as a string), or `NULL` if the argument is null.

An error will occur if the argument is an invalid JSON value.

The following is a complete list of the possible return types:

Return type	Value	Example
ARRAY	JSON array	[1, 2, {"key": "value"}]
OBJECT	JSON object	{"key":"value"}
BOOLEAN	JSON true/false literals	true, false
DOUBLE	A number with at least one floating point decimal.	1.2
INTEGER	A number without a floating point decimal.	1
NULL	JSON null literal (this is returned as a string, not to be confused with the SQL NULL value!)	null
STRING	JSON String	"a sample string"

Examples

```
SELECT JSON_TYPE('{"A": 1, "B": 2, "C": 3}');
+--------------------------------------+
| JSON_TYPE('{"A": 1, "B": 2, "C": 3}') |
+--------------------------------------+
| OBJECT                               |
+--------------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

JSON_UNQUOTE

Syntax

```
JSON_UNQUOTE(val)
```

Description

Unquotes a JSON value, returning a string, or `NULL` if the argument is null.

An error will occur if the given value begins and ends with double quotes and is an invalid JSON string literal.

If the given value is not a JSON string, value is passed through unmodified.

Certain character sequences have special meanings within a string. Usually, a backslash is ignored, but the escape sequences in the table below are recognised by MariaDB, unless the SQL Mode is set to `NO_BACKSLASH_ESCAPES` .

Escape sequence	Character
”	Double quote (“)
\b	Backslash
\f	Formfeed
\n	Newline (linefeed)
\r	Carriage return
\t	Tab
\	Backslash ()
\uXXXX	UTF-8 bytes for Unicode value XXXX

Examples

```
SELECT JSON_UNQUOTE('"Monty"');
+-------------------------+
| JSON_UNQUOTE('"Monty"') |
+-------------------------+
| Monty                   |
+-------------------------+
```

With the default SQL Mode:

```
SELECT JSON_UNQUOTE('Si\bng\ting');
+----------------------------+
| JSON_UNQUOTE('Si\bng\ting') |
+----------------------------+
| Sng   ing                  |
+----------------------------+
```

Setting `NO_BACKSLASH_ESCAPES` :

```
SET @@sql_mode = 'NO_BACKSLASH_ESCAPES';

SELECT JSON_UNQUOTE('Si\bng\ting');
+----------------------------+
| JSON_UNQUOTE('Si\bng\ting') |
+----------------------------+
| Si\bng\ting                |
+----------------------------+
```

See Also

- JSON Arrow Operators — the `->>` operator is shorthand for `JSON_UNQUOTE(JSON_EXTRACT())`.

This page is licensed: CC BY-SA / Gnu FDL

JSON_VALID

Syntax

```
JSON_VALID(value)
```

Description

Indicates whether the given value is a valid JSON document or not. Returns `1` if valid, `0` if not, and `NULL` if the argument is `NULL`.

> **CURRENT**
>
> The `JSON_VALID` function is automatically used as a CHECK constraint for the JSON data type alias in order to ensure that a valid json document is inserted.
>
> **< 10.4.3**
>
> The `JSON_VALID` function is **not** automatically used as a CHECK constraint for the JSON data type alias.

Examples

```
SELECT JSON_VALID('{"id": 1, "name": "Monty"}');
+-----------------------------------------+
| JSON_VALID('{"id": 1, "name": "Monty"}') |
+-----------------------------------------+
|                                       1 |
+-----------------------------------------+

SELECT JSON_VALID('{"id": 1, "name": "Monty", "oddfield"}');
+-----------------------------------------------------+
| JSON_VALID('{"id": 1, "name": "Monty", "oddfield"}') |
+-----------------------------------------------------+
|                                                   0 |
+-----------------------------------------------------+
```

See Also

- JSON video tutorial covering JSON_VALID.

This page is licensed: CC BY-SA / Gnu FDL

JSON_VALUE

Syntax

```
JSON_VALUE(json_doc, path)
```

Description

Given a JSON document, returns the scalar specified by the path. Returns NULL if not given a valid JSON document, or if there is no match.

Examples

```
SELECT json_value('{"key1":123}', '$.key1');
+-------------------------------------+
| json_value('{"key1":123}', '$.key1') |
+-------------------------------------+
| 123                                 |
+-------------------------------------+

SELECT json_value('{"key1": [1,2,3], "key1":123}', '$.key1');
+-------------------------------------------------------+
| json_value('{"key1": [1,2,3], "key1":123}', '$.key1') |
+-------------------------------------------------------+
| 123                                                   |
+-------------------------------------------------------+
```

In the `SET` statement below, two escape characters are needed, as a single escape character would be applied by the SQL parser in the `SET` statement, and the escaped character would not form part of the saved value.

```
SET @json = '{"key1":"60\\" Table", "key2":"1"}';

SELECT JSON_VALUE(@json,'$.key1') AS Name , json_value(@json,'$.key2') as ID;
+-----------+------+
| Name      | ID   |
+-----------+------+
| 60" Table | 1    |
+-----------+------+
```

This page is licensed: CC BY-SA / Gnu FDL

JSON Validation Function

IS JSON

Test whether a JSON expression includes valid data.

Syntax

```
<expr> IS [ NOT ] JSON
       [ { VALUE | ARRAY | OBJECT | SCALAR } ]
       [ { WITH | WITHOUT } UNIQUE [ KEYS ] ]
```

Description

The `IS JSON` is a variant of IS predicate that checks whether an expression contains valid JSON data, with optional constraints on JSON type (VALUE, ARRAY, OBJECT, SCALAR) and key uniqueness.

Example

```
SELECT '{"a": 42}' IS JSON OBJECT;
```

Output

```
+----------------------------+
| '{"a": 42}' IS JSON OBJECT |
+----------------------------+
|                          1|
+----------------------------+
```

Window Functions Overview

Window Functions

Window functions calculate across related rows without collapsing them. Unlike `GROUP BY`, they return one result for each input row.

When to Use Window Functions

Use window functions when you need to:

- Rank rows inside a group.
- Calculate running totals or moving averages.
- Compare a row with earlier or later rows.
- Return the top *N* rows per group.

Basic Syntax

```
window_function(expr) OVER (
  [PARTITION BY expr [, ...]]
  [ORDER BY expr [ASC | DESC] [, ...]]
  [{ROWS | RANGE} frame_clause]
)

frame_clause:
  {frame_border | BETWEEN frame_border AND frame_border}

frame_border:
  UNBOUNDED PRECEDING
  | UNBOUNDED FOLLOWING
  | CURRENT ROW
  | expr PRECEDING
  | expr FOLLOWING
```

You can also define a named window and reuse it:

```
SELECT
  SUM(score) OVER w AS running_total,
  AVG(score) OVER w AS running_avg
FROM student
WINDOW w AS (
  ORDER BY score
  ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW
);
```

Window Functions vs `GROUP BY`

Use `GROUP BY` when you want one output row per group.

Use a window function when you want to keep the original rows and add per-group or per-sequence calculations beside them.

```
SELECT test, AVG(score)
FROM student
GROUP BY test;
```

This returns one row per `test`.

```
SELECT
  name,
  test,
  score,
  AVG(score) OVER (PARTITION BY test) AS avg_by_test
FROM student;
```

This returns every row, plus the average for that row's `test`.

How `OVER` Works

`PARTITION BY`

`PARTITION BY` starts a new calculation for each group.

`ORDER BY`

`ORDER BY` defines the row sequence inside each partition.

Frame

The frame controls which rows contribute to the current result. Aggregate window functions use frames. Ranking functions such as `ROW_NUMBER()` and `RANK()` do not.

> **Warning:**
>
> `OVER ()` uses the whole result set.
>
> For aggregate window functions, `OVER (ORDER BY ...)` uses a running frame by default. In MariaDB, that default is `RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW`.

`ROWS` vs `RANGE`

`ROWS` counts physical rows. `RANGE` groups peer rows that share the same `ORDER BY` value.

Use `ROWS` when you need strict row-by-row stepping. Use `RANGE` when ties should be treated as one peer group.

```
CREATE TABLE t (score INT);
INSERT INTO t VALUES (10), (10), (20);

SELECT
  score,
  SUM(score) OVER (
    ORDER BY score
    ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW
  ) AS rows_sum,
  SUM(score) OVER (
    ORDER BY score
    RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW
  ) AS range_sum
FROM t;
```

This produces different results for the duplicate `10` values:

```
+-------+----------+-----------+
| score | rows_sum | range_sum |
+-------+----------+-----------+
|    10 |       10 |        20 |
|    10 |       20 |        20 |
|    20 |       40 |        40 |
+-------+----------+-----------+
```

Supported Functions

Dedicated window functions include CUME_DIST, DENSE_RANK, FIRST_VALUE, LAG, LAST_VALUE, LEAD, MEDIAN, NTH_VALUE, NTILE, PERCENTILE_CONT, PERCENTILE_DISC, PERCENT_RANK, RANK, and ROW_NUMBER.

Aggregate functions that also work with `OVER (...)` include AVG, BIT_AND, BIT_OR, BIT_XOR, COUNT, MAX, MIN, STD, STDDEV, STDDEV_POP, STDDEV_SAMP, SUM, VAR_POP, VAR_SAMP, and VARIANCE.

Aggregate window functions do not support `DISTINCT`.

Aggregate Functions as Window Functions

It is possible to use aggregate functions as window functions. An aggregate function used as a window function must have the `OVER` clause. For example, here's COUNT() used as a window function:

```
SELECT COUNT(*) OVER (ORDER BY column) FROM table;
```

Common Pitfalls

- You cannot reference a window function in `WHERE`.
- Compute the window result in a subquery or CTE first.
- MariaDB does not support `GROUPS` frames.
- MariaDB does not support frame exclusion.
- MariaDB does not support explicit `NULLS FIRST` or `NULLS LAST`.
- `RANGE` frames do not support `DATE` or `DATETIME` arithmetic.

> **Note:**
>
> Window functions are evaluated after `WHERE`, `GROUP BY`, and `HAVING`. Filter the computed result in an outer query or CTE.

Optimization

Window function evaluation invokes a sort pass per group of compatible windows. Each such pass appears as a `filesort` node in the execution plan. Query shape decides how many passes are needed and how cheap each one is to perform.

`GROUP BY` Comes First

If a query uses both `GROUP BY` and window functions, MariaDB executes the grouping step first. The window step runs on the grouped result.

This affects index usage. An index that helps the base table scan does not automatically avoid later sorting for the window stage.

> **Note:**
>
> When tuning this pattern, optimize the `GROUP BY` step first. Then check `EXPLAIN FORMAT=JSON` to confirm the window step's sort cost is low.

Sort Reuse Depends on Sort Keys

If the `GROUP BY` definition and the window's `PARTITION BY` and `ORDER BY` definition use different sort keys, the window's sort pass cannot reuse the grouped output's order — it has to re-sort the rows. Aligning the keys keeps the sort cheap; misaligning them forces a full sort.

For example, this shape can require an extra sort:

```
SELECT
  dept,
  month,
  SUM(sales) AS monthly_sales,
  ROW_NUMBER() OVER (
    PARTITION BY dept
    ORDER BY month
  ) AS row_num
FROM revenue
GROUP BY month, dept;
```

The grouped result is ordered by `month, dept`. The window step needs `dept, month`. Those orders do not match.

Multiple Window Functions Can Share One Sort

Multiple window functions can share the same sort pass when their `PARTITION BY` and `ORDER BY` clauses are compatible. Two specs are compatible if they are identical, or if one is a prefix of the other — the longer specification then becomes the canonical sort order.

Identical specs:

```
SELECT
  dept,
  month,
  sales,
  ROW_NUMBER() OVER (
    PARTITION BY dept
    ORDER BY month
  ) AS row_num,
  SUM(sales) OVER (
    PARTITION BY dept
    ORDER BY month
    ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW
  ) AS running_sales
FROM revenue;
```

Both window functions use the same partitioning and ordering. MariaDB reuses the same sorted stream for both — one `filesort` pass.

Prefix-compatible specs:

```
SELECT
  dept,
  month,
  day,
  ROW_NUMBER() OVER (PARTITION BY dept ORDER BY month)      AS rn,
  SUM(sales)   OVER (PARTITION BY dept ORDER BY month, day) AS running_sales
FROM revenue;
```

The first window's order key (`dept` , `month`) is a prefix of the second's (`dept` , `month` , `day`). MariaDB sorts once by the longer key (`dept, month, day`) and both window functions consume the result.

Practical Tuning Tips

- Expect `GROUP BY` to shape the input seen by window functions.
- Align `GROUP BY` keys with the window sort keys when possible — the sort still runs, but it is cheap when the data is already in the right order.
- Reuse the same `PARTITION BY` and `ORDER BY` across multiple window functions, or make one a prefix of another, so MariaDB can collapse them into a single sort pass.
- Use `EXPLAIN FORMAT=JSON` (or `ANALYZE FORMAT=JSON` for real timings) to count the window-function sort passes — each pass appears as a `filesort` node under the aggregation step.

Examples

Given the following data:

```
CREATE TABLE student (
  name CHAR(10),
  test CHAR(10),
  score TINYINT
);

INSERT INTO student VALUES
  ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
  ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
  ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
  ('Tatiana', 'SQL', 87), ('Tatiana', 'Tuning', 83);
```

Average by Test

```
SELECT
  name,
  test,
  score,
  AVG(score) OVER (PARTITION BY test) AS avg_by_test
FROM student
ORDER BY test, name;
```

```
+---------+--------+-------+-------------+
| name    | test   | score | avg_by_test |
+---------+--------+-------+-------------+
| Chun    | SQL    |    75 |     65.2500 |
| Esben   | SQL    |    43 |     65.2500 |
| Kaolin  | SQL    |    56 |     65.2500 |
| Tatiana | SQL    |    87 |     65.2500 |
| Chun    | Tuning |    73 |     68.7500 |
| Esben   | Tuning |    31 |     68.7500 |
| Kaolin  | Tuning |    88 |     68.7500 |
| Tatiana | Tuning |    83 |     68.7500 |
+---------+--------+-------+-------------+
```

Running Total by Score

```
SELECT
  name,
  score,
  SUM(score) OVER (
    ORDER BY score
    ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW
  ) AS running_total
FROM student
ORDER BY score;
```

```
+---------+-------+---------------+
| name    | score | running_total |
+---------+-------+---------------+
| Esben   |    31 |            31 |
| Esben   |    43 |            74 |
| Kaolin  |    56 |           130 |
| Chun    |    73 |           203 |
| Chun    |    75 |           278 |
| Tatiana |    83 |           361 |
| Tatiana |    87 |           448 |
| Kaolin  |    88 |           536 |
+---------+-------+---------------+
```

Top 2 Scores per Test

```
WITH ranked AS (
  SELECT
    name,
    test,
    score,
    RANK() OVER (PARTITION BY test ORDER BY score DESC) AS rnk
  FROM student
)
SELECT
  name,
  test,
  score,
  rnk
FROM ranked
WHERE rnk <= 2
ORDER BY test, rnk, name;
```

```
+---------+--------+-------+-----+
| name    | test   | score | rnk |
+---------+--------+-------+-----+
| Tatiana | SQL    |    87 |   1 |
| Chun    | SQL    |    75 |   2 |
| Kaolin  | Tuning |    88 |   1 |
| Tatiana | Tuning |    83 |   2 |
+---------+--------+-------+-----+
```

MariaDB Support and Limitations

MariaDB:

- Supports `ROWS` and `RANGE` frames.
- Supports all frame bounds, including `RANGE n PRECEDING` and `RANGE n FOLLOWING`.
- Does not support `GROUPS` frames.
- Does not support frame exclusion.
- Does not support explicit `NULLS FIRST` or `NULLS LAST`.
- Does not support `DATE` or `DATETIME` arithmetic for `RANGE` frames.
- Does not support `DISTINCT` for aggregate window functions.

Window Frames

Basic Syntax

```
frame_clause:
  {ROWS | RANGE} {frame_border | BETWEEN frame_border AND frame_border}

frame_border:
  | UNBOUNDED PRECEDING
  | UNBOUNDED FOLLOWING
  | CURRENT ROW
  | expr PRECEDING
  | expr FOLLOWING
```

How Window Frames Work

A basic overview of window functions is described in Window Functions Overview. Window frames define which rows contribute to the current result.

Window frames are used by aggregate window functions. They are defined by the frame clause inside `OVER (...)`.

> **Warning:**
>
> `OVER ()` uses the whole result set.
>
> For aggregate window functions, `OVER (ORDER BY ...)` uses a running frame by default. In MariaDB, that default is `RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW`.

Frame Bound Types

Common frame bounds include:

- All rows before the current row (`UNBOUNDED PRECEDING`), for example `RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW`.
- All rows after the current row (UNBOUNDED FOLLOWING), for example `RANGE BETWEEN CURRENT ROW AND UNBOUNDED FOLLOWING`.
- A set number of rows before the current row (`expr PRECEDING`), for example `RANGE BETWEEN 6 PRECEDING AND CURRENT ROW`.
- A set number of rows after the current row (`expr FOLLOWING`), for example `RANGE BETWEEN CURRENT ROW AND 2 FOLLOWING`.
- A specified number of rows both before and after the current row, for example `RANGE BETWEEN 6 PRECEDING AND 3 FOLLOWING`.

`ROWS` vs `RANGE`

`ROWS` counts physical rows. `RANGE` groups peer rows that share the same `ORDER BY` value.

Use `ROWS` when you want strict row-by-row stepping. Use `RANGE` when tied sort values should be treated as one peer group.

Aggregate Functions Using Frames

See list here.

Examples

Take the following example:

```
CREATE TABLE `student_test` (
  name char(10),
  test char(10),
  score tinyint(4)
);

INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87);

SELECT name, test, score, SUM(score)
  OVER () AS total_score
  FROM student_test;
```

```
+---------+--------+-------+-------------+
| name    | test   | score | total_score |
+---------+--------+-------+-------------+
| Chun    | SQL    |    75 |         453 |
| Chun    | Tuning |    73 |         453 |
| Esben   | SQL    |    43 |         453 |
| Esben   | Tuning |    31 |         453 |
| Kaolin  | SQL    |    56 |         453 |
| Kaolin  | Tuning |    88 |         453 |
| Tatiana | SQL    |    87 |         453 |
+---------+--------+-------+-------------+
```

By not specifying an `ORDER BY` clause, SUM runs over the entire result set. If we add `ORDER BY score`, the default running frame is used instead:

```
SELECT name, test, score, SUM(score)
  OVER (ORDER BY score) AS total_score
  FROM student_test ORDER BY score;
```

```
+---------+--------+-------+-------------+
| name    | test   | score | total_score |
+---------+--------+-------+-------------+
| Esben   | Tuning |    31 |          31 |
| Esben   | SQL    |    43 |          74 |
| Kaolin  | SQL    |    56 |         130 |
| Chun    | Tuning |    73 |         203 |
| Chun    | SQL    |    75 |         278 |
| Tatiana | SQL    |    87 |         365 |
| Kaolin  | Tuning |    88 |         453 |
+---------+--------+-------+-------------+
```

The `total_score` column now represents a running total of the current row and all previous rows. The frame expands as the query proceeds.

The previous query relies on the default frame. Written explicitly, it looks like this:

```
SELECT name, test, score, SUM(score)
  OVER (ORDER BY score RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW) AS total_score
  FROM student_test ORDER BY score;
```

```
+---------+--------+-------+-------------+
| name    | test   | score | total_score |
+---------+--------+-------+-------------+
| Esben   | Tuning |    31 |          31 |
| Esben   | SQL    |    43 |          74 |
| Kaolin  | SQL    |    56 |         130 |
| Chun    | Tuning |    73 |         203 |
| Chun    | SQL    |    75 |         278 |
| Tatiana | SQL    |    87 |         365 |
| Kaolin  | Tuning |    88 |         453 |
+---------+--------+-------+-------------+
```

Applying the window function to the current row and all following rows can be done with `UNBOUNDED FOLLOWING`:

```
SELECT name, test, score, SUM(score)
  OVER (ORDER BY score RANGE BETWEEN CURRENT ROW AND UNBOUNDED FOLLOWING) AS total_score
  FROM student_test ORDER BY score;
```

```
+---------+--------+-------+-------------+
| name    | test   | score | total_score |
+---------+--------+-------+-------------+
| Esben   | Tuning |    31 |         453 |
| Esben   | SQL    |    43 |         422 |
| Kaolin  | SQL    |    56 |         379 |
| Chun    | Tuning |    73 |         323 |
| Chun    | SQL    |    75 |         250 |
| Tatiana | SQL    |    87 |         175 |
| Kaolin  | Tuning |    88 |          88 |
+---------+--------+-------+-------------+
```

You can also specify a fixed number of rows instead of an unbounded frame. The following example uses the current row and the previous row:

```
SELECT name, test, score, SUM(score)
  OVER (ORDER BY score ROWS BETWEEN 1 PRECEDING AND CURRENT ROW) AS total_score
  FROM student_test ORDER BY score;
```

```
+---------+--------+-------+-------------+
| name    | test   | score | total_score |
+---------+--------+-------+-------------+
| Esben   | Tuning |    31 |          31 |
| Esben   | SQL    |    43 |          74 |
| Kaolin  | SQL    |    56 |          99 |
| Chun    | Tuning |    73 |         129 |
| Chun    | SQL    |    75 |         148 |
| Tatiana | SQL    |    87 |         162 |
| Kaolin  | Tuning |    88 |         175 |
+---------+--------+-------+-------------+
```

The next example uses the previous row, the current row, and the following row:

```
SELECT name, test, score, SUM(score)
  OVER (ORDER BY score ROWS BETWEEN 1 PRECEDING AND 1 FOLLOWING) AS total_score
  FROM student_test ORDER BY score;
```

```
+---------+--------+-------+-------------+
| name    | test   | score | total_score |
+---------+--------+-------+-------------+
| Esben   | Tuning |    31 |          74 |
| Esben   | SQL    |    43 |         130 |
| Kaolin  | SQL    |    56 |         172 |
| Chun    | Tuning |    73 |         204 |
| Chun    | SQL    |    75 |         235 |
| Tatiana | SQL    |    87 |         250 |
| Kaolin  | Tuning |    88 |         175 |
+---------+--------+-------+-------------+
```

ColumnStore Window Functions

Introduction

MariaDB ColumnStore provides support for window functions broadly following the SQL 2003 specification. A window function allows for calculations relating to a window of data surrounding the current row in a result set. This capability provides for simplified queries in support of common business questions such as cumulative totals, rolling averages, and top 10 lists.

Aggregate functions are utilized for window functions however differ in behavior from a group by query because the rows remain ungrouped. This provides support for cumulative sums and rolling averages, for example.

Two key concepts for window functions are Partition and Frame:

- A Partition is a group of rows, or window, that have the same value for a specific column, for example a Partition can be created over a time period such as a quarter or lookup values.
- The Frame for each row is a subset of the row's Partition. The frame typically is dynamic allowing for a sliding frame of rows within the Partition. The Frame determines the range of rows for the windowing function. A Frame could be defined as the last X rows and next Y rows all the way up to the entire Partition.

Window functions are applied after joins, group by, and having clauses are calculated.

Syntax

A window function is applied in the select clause using the following syntax:

```
function_name ([expression [, expression ... ]]) OVER ( window_definition )
```

where *window_definition* is defined as:

```
[ PARTITION BY expression [, ...] ]
[ ORDER BY expression [ ASC | DESC ] [ NULLS { FIRST | LAST } ] [, ...] ]
[ frame_clause ]
```

`PARTITION BY`:

- Divides the window result set into groups based on one or more expressions.
- An expression may be a constant, column, and non window function expressions.
- A query is not limited to a single partition by clause. Different partition clauses can be used across different window function applications.
- The partition by columns do not need to be in the select list but do need to be available from the query result set.
- If there is no `PARTITION BY` clause, all rows of the result set define the group.

`ORDER BY`:

- Defines the ordering of values within the partition.
- Can be ordered by multiple keys which may be a constant, column or non window function expression.
- The order by columns do not need to be in the select list but need to be available from the query result set.
- Use of a select column alias from the query is not supported.
- `ASC` (default) and `DESC` options allow for ordering ascending or descending.
- `NULLS FIRST` and `NULL_LAST` options specify whether null values come first or last in the ordering sequence. `NULLS_FIRST` is the default for ASC order, and `NULLS_LAST` is the default for `DESC` order.

and the optional *frame_clause* is defined as:

```
{ RANGE | ROWS } frame_start
{ RANGE | ROWS } BETWEEN frame_start AND frame_end
```

and the optional *frame_start* and *frame_end* are defined as (value being a numeric expression):

```
UNBOUNDED PRECEDING
value PRECEDING
CURRENT ROW
value FOLLOWING
UNBOUNDED FOLLOWING
```

RANGE/ROWS:

- Defines the windowing clause for calculating the set of rows that the function applies to for calculating a given rows window function result.
- Requires an `ORDER BY` clause to define the row order for the window.
- `ROWS` specify the window in physical units, i.e. result set rows and must be a constant or expression evaluating to a positive numeric value.
- `RANGE` specifies the window as a logical offset. If the expression evaluates to a numeric value then the `ORDER BY` expression must be a numeric or `DATE` type. If the expression evaluates to an interval value then the `ORDER BY` expression must be a `DATE` data type.
- `UNBOUNDED PRECEDING` indicates the window starts at the first row of the partition.
- `UNBOUNDED FOLLOWING` indicates the window ends at the last row of the partition.
- `CURRENT ROW` specifies the window start or ends at the current row or value.
- If omitted, the default is `ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW`.

Supported Functions

Function	Description
AVG()	The average of all input values.
COUNT()	Number of input rows.
CUME_DIST()	Calculates the cumulative distribution, or relative rank, of the current row to other rows in the same partition. Number of peer or preceding rows / number of rows in partition.
DENSE_RANK()	Ranks items in a group leaving no gaps in ranking sequence when there are ties.
FIRST_VALUE()	The value evaluated at the row that is the first row of the window frame (counting from 1); null if no such row.

Function	Description
LAG()	The value evaluated at the row that is offset rows before the current row within the partition; if there is no such row, instead return default. Both offset and default are evaluated with respect to the current row. If omitted, offset defaults to 1 and default to null. LAG provides access to more than one row of a table at the same time without a self-join. Given a series of rows returned from a query and a position of the cursor, LAG provides access to a row at a given physical offset prior to that position.
LAST_VALUE()	The value evaluated at the row that is the last row of the window frame (counting from 1); null if no such row.
LEAD()	Provides access to a row at a given physical offset beyond that position. Returns value evaluated at the row that is offset rows after the current row within the partition; if there is no such row, instead return default. Both offset and default are evaluated with respect to the current row. If omitted, offset defaults to 1 and default to null.
MAX()	Maximum value of expression across all input values.
MEDIAN()	An inverse distribution function that assumes a continuous distribution model. It takes a numeric or datetime value and returns the middle value or an interpolated value that would be the middle value once the values are sorted. Nulls are ignored in the calculation.
MIN()	Minimum value of expression across all input values.
NTH_VALUE()	The value evaluated at the row that is the nth row of the window frame (counting from 1); null if no such row.
NTILE()	Divides an ordered data set into a number of buckets indicated by expr and assigns the appropriate bucket number to each row. The buckets are numbered 1 through expr. The expr value must resolve to a positive constant for each partition. Integer ranging from 1 to the argument value, dividing the partition as equally as possible.
PERCENT_RANK()	relative rank of the current row: (rank - 1) / (total rows - 1).
PERCENTILE_CONT()	An inverse distribution function that assumes a continuous distribution model. It takes a percentile value and a sort specification, and returns an interpolated value that would fall into that percentile value with respect to the sort specification. Nulls are ignored in the calculation.
PERCENTILE_DISC()	An inverse distribution function that assumes a discrete distribution model. It takes a percentile value and a sort specification and returns an element from the set. Nulls are ignored in the calculation.
RANK()	rank of the current row with gaps; same as row_number of its first peer.
ROW_NUMBER()	number of the current row within its partition, counting from 1
STDDEV() STDDEV_POP()	Computes the population standard deviation and returns the square root of the population variance.
STDDEV_SAMP()	Computes the cumulative sample standard deviation and returns the square root of the sample variance.
SUM()	Sum of expression across all input values.
VARIANCE() VAR_POP()	Population variance of the input values (square of the population standard deviation).
VAR_SAMP()	Sample variance of the input values (square of the sample standard deviation).

Examples

Example Schema

The examples are all based on the following simplified sales opportunity table:

```
CREATE TABLE opportunities (
id INT,
accountName VARCHAR(20),
name VARCHAR(128),
owner VARCHAR(7),
amount DECIMAL(10,2),
closeDate DATE,
stageName VARCHAR(11)
) ENGINE=columnstore;
```

Some example values are (thanks to www.mockaroo.com for sample data generation):

id	accountName	name	owner	amount	closeDate	stageName
1	Browseblab	Multi-lateral executive function	Bob	26444.86	2016-10-20	Negotiating
2	Mita	Organic demand-driven benchmark	Maria	477878.41	2016-11-28	ClosedWon
3	Miboo	De-engineered hybrid groupware	Olivier	80181.78	2017-01-05	ClosedWon
4	Youbridge	Enterprise-wide bottom-line Graphic Interface	Chris	946245.29	2016-07-02	ClosedWon
5	Skyba	Reverse-engineered fresh-thinking standardization	Maria	696241.82	2017-02-17	Negotiating
6	Eayo	Fundamental well-modulated artificial intelligence	Bob	765605.52	2016-08-27	Prospecting
7	Yotz	Extended secondary infrastructure	Chris	319624.20	2017-01-06	ClosedLost
8	Oloo	Configurable web-enabled data-warehouse	Chris	321016.26	2017-03-08	ClosedLost
9	Kaymbo	Multi-lateral web-enabled definition	Bob	690881.01	2017-01-02	Developing
10	Rhyloo	Public-key coherent infrastructure	Chris	965477.74	2016-11-07	Prospecting

The schema, sample data, and queries are available as an attachment to this article.

Cumulative Sum and Running Max Example

Window functions can be used to achieve cumulative / running calculations on a detail report. In this case a won opportunity report for a 7 day period adds columns to show the accumulated won amount as well as the current highest opportunity amount in preceding rows.

```
SELECT owner,
accountName,
CloseDate,
amount,
SUM(amount) OVER (ORDER BY CloseDate ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW) cumeWon,
MAX(amount) OVER (ORDER BY CloseDate ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW) runningMax
FROM opportunities
WHERE stageName='ClosedWon'
AND closeDate >= '2016-10-02' AND closeDate <= '2016-10-09'
ORDER BY CloseDate;
```

with example results:

owner	accountName	CloseDate	amount	cumeWon	runningMax
Bill	Babbleopia	2016-10-02	437636.47	437636.47	437636.47

Partitioned Cumulative Sum and Running Max Example

The above example can be partitioned, so that the window functions are over a particular field grouping such as owner and accumulate within that grouping. This is achieved by adding the syntax “partition by” in the window function clause.

```
SELECT owner,
accountName,
CloseDate,
amount,
SUM(amount) OVER (PARTITION BY owner ORDER BY CloseDate ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW)
cumeWon,
MAX(amount) OVER (PARTITION BY owner ORDER BY CloseDate ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW)
runningMax
FROM opportunities
WHERE stageName='ClosedWon'
AND closeDate >= '2016-10-02' AND closeDate <= '2016-10-09'
ORDER BY owner, CloseDate;
```

With example results:

owner	accountName	CloseDate	amount	cumeWon	runningMax
Bill	Babbleopia	2016-10-02	437636.47	437636.47	437636.47
Bill	Thoughtworks	2016-10-04	146086.51	583722.98	437636.47
Bill	Latz	2016-10-08	857254.87	1440977.85	857254.87
Chris	Linkbridge	2016-10-07	539977.45	539977.45	539977.45
Chris	Avamm	2016-10-09	699566.86	1239544.31	699566.86
Olivier	Devpulse	2016-10-05	834235.93	834235.93	834235.93
Olivier	Trupe	2016-10-07	500802.29	1335038.22	834235.93

Ranking / Top Results

The rank window function allows for ranking or assigning a numeric order value based on the window function definition. Using the `Rank()` function will result in the same value for ties / equal values and the next rank value skipped. The `Dense_Rank()` function behaves similarly except the next consecutive number is used after a tie rather than skipped. The `Row_Number()` function will provide a unique ordering value. The example query shows the `Rank()` function being applied to rank sales reps by the number of opportunities for Q4 2016.

```
SELECT owner,
wonCount,
rank() OVER (ORDER BY wonCount DESC) rank
FROM (
  SELECT owner,
  COUNT(*) wonCount
  FROM opportunities
  WHERE stageName='ClosedWon'
  AND closeDate >= '2016-10-01' AND closeDate < '2016-12-31'
  GROUP BY owner
) t
ORDER BY rank;
```

with example results (note the query is technically incorrect by using closeDate < '2016-12-31' however this creates a tie scenario for illustrative purposes):

owner	wonCount	rank
Bill	19	1
Chris	15	2
Maria	14	3
Bob	14	3
Olivier	10	5

If the `dense_rank` function is used the rank values would be 1,2,3,3,4 and for the `row_number` function the values would be 1,2,3,4,5.

First and Last Values

The first_value and last_value functions allow determining the first and last values of a given range. Combined with a group by this allows summarizing opening and closing values. The example shows a more complex case where detailed information is presented for first and last opportunity by quarter.

```
SELECT a.YEAR,
a.quarter,
f.accountName firstAccountName,
f.owner firstOwner,
f.amount firstAmount,
l.accountName lastAccountName,
l.owner lastOwner,
l.amount lastAmount
FROM (
  SELECT YEAR,
  QUARTER,
  MIN(firstId) firstId,
  MIN(lastId) lastId
  FROM (
    SELECT YEAR(closeDate) YEAR,
    quarter(closeDate) QUARTER,
    first_value(id) OVER (PARTITION BY YEAR(closeDate), quarter(closeDate) ORDER BY closeDate ROWS
BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW) firstId,
    last_value(id) OVER (PARTITION BY YEAR(closeDate), quarter(closeDate) ORDER BY closeDate ROWS BETWEEN
CURRENT ROW AND UNBOUNDED FOLLOWING) lastId
    FROM opportunities  WHERE stageName='ClosedWon'
  ) t
  GROUP BY YEAR, QUARTER ORDER BY YEAR,QUARTER
) a
JOIN opportunities f ON a.firstId = f.id
JOIN opportunities l ON a.lastId = l.id
ORDER BY YEAR, QUARTER;
```

with example results:

year	quarter	firstAccountName	firstOwner	firstAmount	lastAccountName	lastOwner	lastAmount
2016	3	Skidoo	Bill	523295.07	Skipstorm	Bill	151420.86
2016	4	Skimia	Chris	961513.59	Avamm	Maria	112493.65
2017	1	Yombu	Bob	536875.51	Skaboo	Chris	270273.08

Prior and Next Example

Sometimes it useful to understand the previous and next values in the context of a given row. The lag and lead window functions provide this capability. By default the offset is one providing the prior or next value but can also be provided to get a larger offset. The example query is a report of opportunities by account name showing the opportunity amount, and the prior and next opportunity amount for that account by close date.

```
SELECT accountName,
closeDate,
amount currentOppAmount,
lag(amount) OVER (PARTITION BY accountName ORDER BY closeDate) priorAmount, lead(amount) OVER (PARTITION
BY accountName ORDER BY closeDate) nextAmount
FROM opportunities
ORDER BY accountName, closeDate
LIMIT 9;
```

With example results:

accountName	closeDate	currentOppAmount	priorAmount	nextAmount
Abata	2016-09-10	645098.45	NULL	161086.82
Abata	2016-10-14	161086.82	645098.45	350235.75
Abata	2016-12-18	350235.75	161086.82	878595.89
Abata	2016-12-31	878595.89	350235.75	922322.39
Abata	2017-01-21	922322.39	878595.89	NULL
Abatz	2016-10-19	795424.15	NULL	NULL
Agimba	2016-07-09	288974.84	NULL	914461.49
Agimba	2016-09-07	914461.49	288974.84	176645.52
Agimba	2016-09-20	176645.52	914461.49	NULL

Quartiles Example

The NTile window function allows for breaking up a data set into portions assigned a numeric value to each portion of the range. NTile(4) breaks the data up into quartiles (4 sets). The example query produces a report of all opportunities summarizing the quartile boundaries of amount values.

```
SELECT t.quartile,
MIN(t.amount) MIN,
MAX(t.amount) MAX
FROM (
  SELECT amount,
  ntile(4) OVER (ORDER BY amount ASC) quartile
  FROM opportunities
  WHERE closeDate >= '2016-10-01' AND closeDate <= '2016-12-31'
  ) t
GROUP BY quartile
ORDER BY quartile;
```

With example results:

quartile	min	max
1	6337.15	287634.01
2	288796.14	539977.45
3	540070.04	748727.51
4	753670.77	998864.47

Percentile Example

The percentile functions have a slightly different syntax from other window functions as can be seen in the example below. These functions can be only applied against numeric values. The argument to the function is the percentile to evaluate. Following ‘within group’ is the sort expression which indicates the sort column and optionally order. Finally after ‘over’ is an optional partition by clause, for no partition clause use ‘over ()’. The example below utilizes the value 0.5 to calculate the median opportunity amount in the rows. The values differ sometimes because percentile_cont will return the average of the 2 middle rows for an even data set while percentile_desc returns the first encountered in the sort.

```
SELECT owner,
accountName,
CloseDate,
amount,
percentile_cont(0.5) within GROUP (ORDER BY amount) OVER (PARTITION BY owner) pct_cont,
percentile_disc(0.5) within GROUP (ORDER BY amount) OVER (PARTITION BY owner) pct_disc
FROM opportunities
WHERE stageName='ClosedWon'
AND closeDate >= '2016-10-02' AND closeDate <= '2016-10-09'
ORDER BY owner, CloseDate;
```

With example results:

owner	accountName	CloseDate	amount	pct_cont	pct_disc
Bill	Babbleopia	2016-10-02	437636.47	437636.4700000000	437636.47
Bill	Thoughtworks	2016-10-04	146086.51	437636.4700000000	437636.47
Bill	Latz	2016-10-08	857254.87	437636.4700000000	437636.47
Chris	Linkbridge	2016-10-07	539977.45	619772.1550000000	539977.45
Chris	Avamm	2016-10-09	699566.86	619772.1550000000	539977.45
Olivier	Devpulse	2016-10-05	834235.93	667519.1100000000	500802.29
Olivier	Trupe	2016-10-07	500802.29	667519.1100000000	500802.29

CUME_DIST

Syntax

```
CUME_DIST() OVER (
  [ PARTITION BY partition_expression ]
  [ ORDER BY order_list ]
)
```

Description

`CUME_DIST()` is a window function that returns the cumulative distribution of a given row. The following formula is used to calculate the value:

```
(number of rows <= current row) / (total rows)
```

Examples

```
create table t1 (
  pk int primary key,
  a int,
  b int
);

insert into t1 values
( 1 , 0, 10),
( 2 , 0, 10),
( 3 , 1, 10),
( 4 , 1, 10),
( 8 , 2, 10),
( 5 , 2, 20),
( 6 , 2, 20),
( 7 , 2, 20),
( 9 , 4, 20),
(10 , 4, 20);

select pk, a, b,
    rank() over (order by a) as rank,
    percent_rank() over (order by a) as pct_rank,
    cume_dist() over (order by a) as cume_dist
from t1;
+----+------+------+------+--------------+--------------+
| pk | a    | b    | rank | pct_rank     | cume_dist    |
+----+------+------+------+--------------+--------------+
|  1 |    0 |   10 |    1 | 0.0000000000 | 0.2000000000 |
|  2 |    0 |   10 |    1 | 0.0000000000 | 0.2000000000 |
|  3 |    1 |   10 |    3 | 0.2222222222 | 0.4000000000 |
|  4 |    1 |   10 |    3 | 0.2222222222 | 0.4000000000 |
|  5 |    2 |   20 |    5 | 0.4444444444 | 0.8000000000 |
|  6 |    2 |   20 |    5 | 0.4444444444 | 0.8000000000 |
|  7 |    2 |   20 |    5 | 0.4444444444 | 0.8000000000 |
|  8 |    2 |   10 |    5 | 0.4444444444 | 0.8000000000 |
|  9 |    4 |   20 |    9 | 0.8888888889 | 1.0000000000 |
| 10 |    4 |   20 |    9 | 0.8888888889 | 1.0000000000 |
+----+------+------+------+--------------+--------------+

select pk, a, b,
       percent_rank() over (order by pk) as pct_rank,
       cume_dist() over (order by pk) as cume_dist
from t1 order by pk;
+----+------+------+--------------+--------------+
| pk | a    | b    | pct_rank     | cume_dist    |
+----+------+------+--------------+--------------+
|  1 |    0 |   10 | 0.0000000000 | 0.1000000000 |
|  2 |    0 |   10 | 0.1111111111 | 0.2000000000 |
|  3 |    1 |   10 | 0.2222222222 | 0.3000000000 |
|  4 |    1 |   10 | 0.3333333333 | 0.4000000000 |
|  5 |    2 |   20 | 0.4444444444 | 0.5000000000 |
|  6 |    2 |   20 | 0.5555555556 | 0.6000000000 |
|  7 |    2 |   20 | 0.6666666667 | 0.7000000000 |
|  8 |    2 |   10 | 0.7777777778 | 0.8000000000 |
|  9 |    4 |   20 | 0.8888888889 | 0.9000000000 |
| 10 |    4 |   20 | 1.0000000000 | 1.0000000000 |
+----+------+------+--------------+--------------+

select pk, a, b,
        percent_rank() over (partition by a order by a) as pct_rank,
        cume_dist() over (partition by a order by a) as cume_dist
from t1;
+----+------+------+--------------+--------------+
| pk | a    | b    | pct_rank     | cume_dist    |
+----+------+------+--------------+--------------+
|  1 |    0 |   10 | 0.0000000000 | 1.0000000000 |
|  2 |    0 |   10 | 0.0000000000 | 1.0000000000 |
|  3 |    1 |   10 | 0.0000000000 | 1.0000000000 |
```

```
|  4 |    1 |   10 | 0.0000000000 | 1.0000000000 |
|  5 |    2 |   20 | 0.0000000000 | 1.0000000000 |
|  6 |    2 |   20 | 0.0000000000 | 1.0000000000 |
|  7 |    2 |   20 | 0.0000000000 | 1.0000000000 |
|  8 |    2 |   10 | 0.0000000000 | 1.0000000000 |
|  9 |    4 |   20 | 0.0000000000 | 1.0000000000 |
| 10 |    4 |   20 | 0.0000000000 | 1.0000000000 |
+----+------+------+--------------+--------------+
```

DENSE_RANK

Syntax

```
DENSE_RANK() OVER (
  [ PARTITION BY partition_expression ]
  [ ORDER BY order_list ]
)
```

Description

`DENSE_RANK()` is a window function that displays the number of a given row, starting at one and following the ORDER BY sequence of the window function, with identical values receiving the same result. Unlike the RANK() function, there are no skipped values if the preceding results are identical. It is also similar to the ROW_NUMBER() function except that in that function, identical values will receive a different row number for each result.

Examples

The distinction between `DENSE_RANK()`, RANK() and ROW_NUMBER():

```
CREATE TABLE student(course VARCHAR(10), mark int, name varchar(10));

INSERT INTO student VALUES
  ('Maths', 60, 'Thulile'),
  ('Maths', 60, 'Pritha'),
  ('Maths', 70, 'Voitto'),
  ('Maths', 55, 'Chun'),
  ('Biology', 60, 'Bilal'),
   ('Biology', 70, 'Roger');

SELECT
  RANK() OVER (PARTITION BY course ORDER BY mark DESC) AS rank,
  DENSE_RANK() OVER (PARTITION BY course ORDER BY mark DESC) AS dense_rank,
  ROW_NUMBER() OVER (PARTITION BY course ORDER BY mark DESC) AS row_num,
  course, mark, name
FROM student ORDER BY course, mark DESC;
+------+------------+---------+---------+------+---------+
| rank | dense_rank | row_num | course  | mark | name    |
+------+------------+---------+---------+------+---------+
|    1 |          1 |       1 | Biology |   70 | Roger   |
|    2 |          2 |       2 | Biology |   60 | Bilal   |
|    1 |          1 |       1 | Maths   |   70 | Voitto  |
|    2 |          2 |       2 | Maths   |   60 | Thulile |
|    2 |          2 |       3 | Maths   |   60 | Pritha  |
|    4 |          3 |       4 | Maths   |   55 | Chun    |
+------+------------+---------+---------+------+---------+
```

FIRST_VALUE

Syntax

```
FIRST_VALUE(expr) OVER (
  [ PARTITION BY partition_expression ]
  [ ORDER BY order_list ]
)
```

Description

`FIRST_VALUE` returns the first result from an ordered set, or NULL if no such result exists.

Examples

```
CREATE TABLE t1 (
  pk int primary key,
  a int,
  b int,
  c char(10),
  d decimal(10, 3),
  e real
);

INSERT INTO t1 VALUES
( 1, 0, 1,    'one',    0.1,  0.001),
( 2, 0, 2,    'two',    0.2,  0.002),
( 3, 0, 3,    'three',  0.3,  0.003),
( 4, 1, 2,    'three',  0.4,  0.004),
( 5, 1, 1,    'two',    0.5,  0.005),
( 6, 1, 1,    'one',    0.6,  0.006),
( 7, 2, NULL, 'n_one',  0.5,  0.007),
( 8, 2, 1,    'n_two',  NULL, 0.008),
( 9, 2, 2,    NULL,     0.7,  0.009),
(10, 2, 0,    'n_four', 0.8,  0.010),
(11, 2, 10,   NULL,     0.9,  NULL);

SELECT pk, FIRST_VALUE(pk) OVER (ORDER BY pk) AS first_asc,
           LAST_VALUE(pk) OVER (ORDER BY pk) AS last_asc,
           FIRST_VALUE(pk) OVER (ORDER BY pk DESC) AS first_desc,
           LAST_VALUE(pk) OVER (ORDER BY pk DESC) AS last_desc
FROM t1
ORDER BY pk DESC;

+----+-----------+----------+------------+-----------+
| pk | first_asc | last_asc | first_desc | last_desc |
+----+-----------+----------+------------+-----------+
| 11 |         1 |       11 |         11 |        11 |
| 10 |         1 |       10 |         11 |        10 |
|  9 |         1 |        9 |         11 |         9 |
|  8 |         1 |        8 |         11 |         8 |
|  7 |         1 |        7 |         11 |         7 |

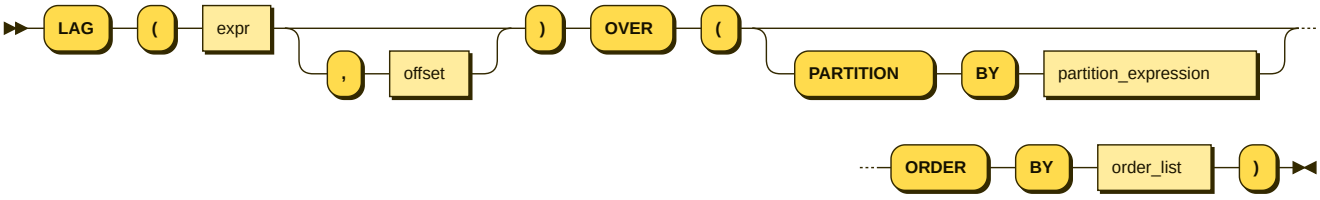
LAG

Syntax

```
LAG (expr[, offset]) OVER (
  [ PARTITION BY partition_expression ]
  < ORDER BY order_list >
)
```



Railroad diagram of LAG — equivalent to the BNF above

Description

The `LAG` function accesses data from a previous row according to the `ORDER BY` clause without the need for a self-join. The specific row is determined by the *offset* (default *1*), which specifies the number of rows behind the current row to use. An offset of *0* is the current row.

Examples

```
CREATE TABLE t1 (pk int primary key, a int, b int, c char(10), d decimal(10, 3), e real);

INSERT INTO t1 VALUES
 ( 1, 0, 1,    'one',    0.1,  0.001),
 ( 2, 0, 2,    'two',    0.2,  0.002),
 ( 3, 0, 3,    'three',  0.3,  0.003),
 ( 4, 1, 2,    'three',  0.4,  0.004),
 ( 5, 1, 1,    'two',    0.5,  0.005),
 ( 6, 1, 1,    'one',    0.6,  0.006),
 ( 7, 2, NULL, 'n_one',  0.5,  0.007),
 ( 8, 2, 1,    'n_two',  NULL, 0.008),
 ( 9, 2, 2,    NULL,     0.7,  0.009),
 (10, 2, 0,    'n_four', 0.8,  0.010),
 (11, 2, 10,   NULL,     0.9,  NULL);

SELECT pk, LAG(pk) OVER (ORDER BY pk) AS l,
  LAG(pk,1) OVER (ORDER BY pk) AS l1,
  LAG(pk,2) OVER (ORDER BY pk) AS l2,
  LAG(pk,0) OVER (ORDER BY pk) AS l0,
  LAG(pk,-1) OVER (ORDER BY pk) AS lm1,
  LAG(pk,-2) OVER (ORDER BY pk) AS lm2
FROM t1;
+----+------+------+------+------+------+------+
| pk | l    | l1   | l2   | l0   | lm1  | lm2  |
+----+------+------+------+------+------+------+
|  1 | NULL | NULL | NULL |    1 |    2 |    3 |

- LEAD - Window function to access a following row

This page is licensed: CC BY-SA / Gnu FDL

LEAD

Syntax

```
LEAD (expr[, offset]) OVER (
  [ PARTITION BY partition_expression ]
  [ ORDER BY order_list ]
)
```

Description

The `LEAD` function accesses data from a following row in the same result set without the need for a self-join. The specific row is determined by the *offset* (default *1*), which specifies the number of rows ahead the current row to use. An offset of *0* is the current row.

Example

```
CREATE TABLE t1 (pk int primary key, a int, b int, c char(10), d decimal(10, 3), e real);

INSERT INTO t1 VALUES
 ( 1, 0, 1,    'one',    0.1,  0.001),
 ( 2, 0, 2,    'two',    0.2,  0.002),
 ( 3, 0, 3,    'three',  0.3,  0.003),
 ( 4, 1, 2,    'three',  0.4,  0.004),
 ( 5, 1, 1,    'two',    0.5,  0.005),
 ( 6, 1, 1,    'one',    0.6,  0.006),
 ( 7, 2, NULL, 'n_one',  0.5,  0.007),
 ( 8, 2, 1,    'n_two',  NULL, 0.008),
 ( 9, 2, 2,    NULL,     0.7,  0.009),
 (10, 2, 0,    'n_four', 0.8,  0.010),
 (11, 2, 10,   NULL,     0.9,  NULL);

MEDIAN

Syntax

```
MEDIAN(median expression) OVER (
  [ PARTITION BY partition_expression ]
)
```

Description

`MEDIAN()` is a window function that returns the median value of a range of values.

It is a specific case of PERCENTILE_CONT, with an argument of 0.5 and the ORDER BY column the one in `MEDIAN`'s argument.

```
MEDIAN(<median-arg>) OVER ( [ PARTITION BY partition_expression] )
```

Is equivalent to:

```
PERCENTILE_CONT(0.5) WITHIN
  GROUP (ORDER BY <median-arg>) OVER ( [ PARTITION BY partition_expression ])
```

Examples

```
CREATE TABLE book_rating (name CHAR(30), star_rating TINYINT);

INSERT INTO book_rating VALUES ('Lord of the Ladybirds', 5);
INSERT INTO book_rating VALUES ('Lord of the Ladybirds', 3);
INSERT INTO book_rating VALUES ('Lady of the Flies', 1);
INSERT INTO book_rating VALUES ('Lady of the Flies', 2);
INSERT INTO book_rating VALUES ('Lady of the Flies', 5);

SELECT name, median(star_rating) OVER (PARTITION BY name) FROM book_rating;
+----------------------+-------------------------------------------+
| name                 | median(star_rating) OVER (PARTITION BY name) |
+----------------------+-------------------------------------------+
| Lord of the Ladybirds |                                4.0000000000 |
| Lord of the Ladybirds |                                4.0000000000 |
| Lady of the Flies     |                                2.0000000000 |
| Lady of the Flies     |                                2.0000000000 |
| Lady of the Flies     |                                2.0000000000 |
+----------------------+-------------------------------------------+

NTH_VALUE

Syntax

```
NTH_VALUE (expr[, num_row]) OVER (
  [ PARTITION BY partition_expression ]
  [ ORDER BY order_list ]
)
```

Description

The `NTH_VALUE` function returns the value evaluated at row number `num_row` of the window frame, starting from 1, or `NULL` if the row does not exist.

NTILE

Syntax

```
NTILE (expr) OVER (
  [ PARTITION BY partition_expression ]
  [ ORDER BY order_list ]
)
```

Description

`NTILE()` is a window function that returns an integer indicating which group a given row falls into. The number of groups is specified in the argument (*expr*), starting at one. Ordered rows in the partition are divided into the specified number of groups with as equal a size as possible.

Examples

```
create table t1 (
    pk int primary key,
    a int,
    b int
  );

insert into t1 values
    (11 , 0, 10),
    (12 , 0, 10),
    (13 , 1, 10),
    (14 , 1, 10),
    (18 , 2, 10),
    (15 , 2, 20),
    (16 , 2, 20),
    (17 , 2, 20),
    (19 , 4, 20),
    (20 , 4, 20);

select pk, a, b,
    ntile(1) over (order by pk)
  from t1;
+----+------+------+-----------------------------+
| pk | a    | b    | ntile(1) over (order by pk) |
+----+------+------+-----------------------------+
| 11 |    0 |   10 |                           1 |
| 12 |    0 |   10 |                           1 |
| 13 |    1 |   10 |                           1 |
| 14 |    1 |   10 |                           1 |
| 15 |    2 |   20 |                           1 |
| 16 |    2 |   20 |                           1 |
| 17 |    2 |   20 |                           1 |
| 18 |    2 |   10 |                           1 |

PERCENT_RANK

Syntax

```
PERCENT_RANK() OVER (
  [ PARTITION BY partition_expression ]
  [ ORDER BY order_list ]
)
```

Description

`PERCENT_RANK()` is a window function that returns the relative percent rank of a given row. The following formula is used to calculate the percent rank:

```
(rank - 1) / (number of rows in the window or partition - 1)
```

Examples

```
create table t1 (
  pk int primary key,
  a int,
  b int
);

insert into t1 values
( 1 , 0, 10),
( 2 , 0, 10),
( 3 , 1, 10),
( 4 , 1, 10),
( 8 , 2, 10),
( 5 , 2, 20),
( 6 , 2, 20),
( 7 , 2, 20),
( 9 , 4, 20),
(10 , 4, 20);

select pk, a, b,
    rank() over (order by a) as rank,
    percent_rank() over (order by a) as pct_rank,
    cume_dist() over (order by a) as cume_dist
from t1;
+----+------+------+------+--------------+--------------+
| pk | a    | b    | rank | pct_rank     | cume_dist    |
+----+------+------+------+--------------+--------------+
|  1 |    0 |   10 |    1 | 0.0000000000 | 0.2000000000 |
|  2 |    0 |   10 |    1 | 0.0000000000 | 0.2000000000 |
|  3 |    1 |   10 |    3 | 0.2222222222 | 0.4000000000 |
|  4 |    1 |   10 |    3 | 0.2222222222 | 0.4000000000 |
|  5 |    2 |   20 |    5 | 0.4444444444 | 0.8000000000 |
|  6 |    2 |   20 |    5 | 0.4444444444 | 0.8000000000 |
|  7 |    2 |   20 |    5 | 0.4444444444 | 0.8000000000 |
|  8 |    2 |   10 |    5 | 0.4444444444 | 0.8000000000 |
|  9 |    4 |   20 |    9 | 0.8888888889 | 1.0000000000 |
| 10 |    4 |   20 |    9 | 0.8888888889 | 1.0000000000 |
+----+------+------+------+--------------+--------------+

select pk, a, b,
       percent_rank() over (order by pk) as pct_rank,
       cume_dist() over (order by pk) as cume_dist
from t1 order by pk;
+----+------+------+--------------+--------------+
| pk | a    | b    | pct_rank     | cume_dist    |
+----+------+------+--------------+--------------+
|  1 |    0 |   10 | 0.0000000000 | 0.1000000000 |

PERCENTILE_CONT

Syntax

Description

`PERCENTILE_CONT()` (standing for continuous percentile) is a window function which returns a value which corresponds to the given fraction in the sort order. If required, it will interpolate between adjacent input items.

Essentially, the following process is followed to find the value to return:

- Get the number of rows in the partition, denoted by N
- RN = p*(N-1), where p denotes the argument to the PERCENTILE_CONT function
- Calculate FRN as FRN=floor(RN) and CRN as CRN=ceil(RN)
- Look up rows FRN and CRN
- If (CRN = FRN = RN) then the result is (value of expression from row at RN)
- Otherwise the result is
- (CRN - RN) * (value of expression for row at FRN) +
- (RN - FRN) * (value of expression for row at CRN)

The MEDIAN function is a specific case of `PERCENTILE_CONT`, equivalent to `PERCENTILE_CONT(0.5)`.

Examples

```
CREATE TABLE book_rating (name CHAR(30), star_rating TINYINT);

INSERT INTO book_rating VALUES ('Lord of the Ladybirds', 5);
INSERT INTO book_rating VALUES ('Lord of the Ladybirds', 3);
INSERT INTO book_rating VALUES ('Lady of the Flies', 1);
INSERT INTO book_rating VALUES ('Lady of the Flies', 2);
INSERT INTO book_rating VALUES ('Lady of the Flies', 5);

SELECT name, PERCENTILE_CONT(0.5) WITHIN GROUP (ORDER BY star_rating)
  OVER (PARTITION BY name) AS pc
  FROM book_rating;
+----------------------+--------------+
| name                 | pc           |
+----------------------+--------------+
| Lord of the Ladybirds | 4.0000000000 |
| Lord of the Ladybirds | 4.0000000000 |
| Lady of the Flies     | 2.0000000000 |
| Lady of the Flies     | 2.0000000000 |
| Lady of the Flies     | 2.0000000000 |
+----------------------+--------------+

SELECT name, PERCENTILE_CONT(1) WITHIN GROUP (ORDER BY star_rating)
  OVER (PARTITION BY name) AS pc
  FROM book_rating;

PERCENTILE_DISC

Syntax

Description

`PERCENTILE_DISC()` (standing for discrete percentile) is a window function which returns the first value in the set whose ordered position is the same or more than the specified fraction.

Essentially, the following process is followed to find the value to return:

- Get the number of rows in the partition.
- Walk through the partition, in order, until finding the first row with CUME_DIST() >= function_argument.

Examples

```
CREATE TABLE book_rating (name CHAR(30), star_rating TINYINT);

INSERT INTO book_rating VALUES ('Lord of the Ladybirds', 5);
INSERT INTO book_rating VALUES ('Lord of the Ladybirds', 3);
INSERT INTO book_rating VALUES ('Lady of the Flies', 1);
INSERT INTO book_rating VALUES ('Lady of the Flies', 2);
INSERT INTO book_rating VALUES ('Lady of the Flies', 5);

SELECT name, PERCENTILE_DISC(0.5) WITHIN GROUP (ORDER BY star_rating)
  OVER (PARTITION BY name) AS pc FROM book_rating;
+-----------------------+------+
| name                  | pc   |
+-----------------------+------+
| Lord of the Ladybirds |    3 |
| Lord of the Ladybirds |    3 |
| Lady of the Flies     |    2 |
| Lady of the Flies     |    2 |
| Lady of the Flies     |    2 |
+-----------------------+------+
5 rows in set (0.000 sec)

SELECT name, PERCENTILE_DISC(0) WITHIN GROUP (ORDER BY star_rating)
 OVER (PARTITION BY name) AS pc FROM book_rating;
+-----------------------+------+
| name                  | pc   |
+-----------------------+------+
| Lord of the Ladybirds |    3 |
| Lord of the Ladybirds |    3 |
| Lady of the Flies     |    1 |
| Lady of the Flies     |    1 |
| Lady of the Flies     |    1 |
+-----------------------+------+
5 rows in set (0.000 sec)

SELECT name, PERCENTILE_DISC(1) WITHIN GROUP (ORDER BY star_rating)
  OVER (PARTITION BY name) AS pc FROM book_rating;
+-----------------------+------+
| name                  | pc   |
+-----------------------+------+
| Lord of the Ladybirds |    5 |
| Lord of the Ladybirds |    5 |
| Lady of the Flies     |    5 |
| Lady of the Flies     |    5 |
| Lady of the Flies     |    5 |
+-----------------------+------+
5 rows in set (0.000 sec)

SELECT name, PERCENTILE_DISC(0.6) WITHIN GROUP (ORDER BY star_rating)
  OVER (PARTITION BY name) AS pc FROM book_rating;
+-----------------------+------+
| name                  | pc   |
+-----------------------+------+
| Lord of the Ladybirds |    5 |
| Lord of the Ladybirds |    5 |
| Lady of the Flies     |    2 |
| Lady of the Flies     |    2 |
| Lady of the Flies     |    2 |

RANK

Syntax

```
RANK() OVER (
  [ PARTITION BY partition_expression ]
  [ ORDER BY order_list ]
)
```

Description

RANK() is a window function that displays the number of a given row, starting at one and following the ORDER BY sequence of the window function, with identical values receiving the same result. It is similar to the ROW_NUMBER() function except that in that function, identical values will receive a different row number for each result.

Examples

The distinction between DENSE_RANK(), RANK() and ROW_NUMBER():

```
CREATE TABLE student(course VARCHAR(10), mark int, name varchar(10));

INSERT INTO student VALUES
  ('Maths', 60, 'Thulile'),
  ('Maths', 60, 'Pritha'),
  ('Maths', 70, 'Voitto'),
  ('Maths', 55, 'Chun'),
  ('Biology', 60, 'Bilal'),
   ('Biology', 70, 'Roger');

SELECT
  RANK() OVER (PARTITION BY course ORDER BY mark DESC) AS rank,
  DENSE_RANK() OVER (PARTITION BY course ORDER BY mark DESC) AS dense_rank,
  ROW_NUMBER() OVER (PARTITION BY course ORDER BY mark DESC) AS row_num,
  course, mark, name
FROM student ORDER BY course, mark DESC;
+------+------------+---------+---------+------+---------+
| rank | dense_rank | row_num | course  | mark | name    |
+------+------------+---------+---------+------+---------+
|    1 |          1 |       1 | Biology |   70 | Roger   |
|    2 |          2 |       2 | Biology |   60 | Bilal   |
|    1 |          1 |       1 | Maths   |   70 | Voitto  |
|    2 |          2 |       2 | Maths   |   60 | Thulile |
|    2 |          2 |       3 | Maths   |   60 | Pritha  |
|    4 |          3 |       4 | Maths   |   55 | Chun    |
+------+------------+---------+---------+------+---------+
```

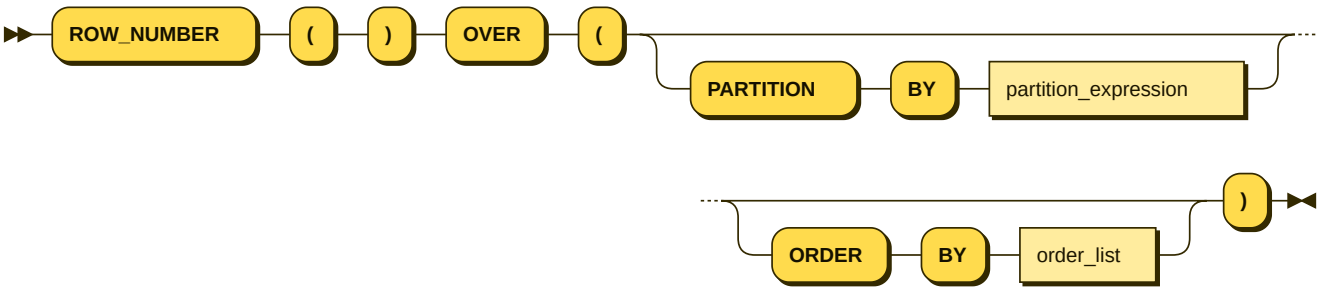
ROW_NUMBER

Syntax

```
ROW_NUMBER() OVER (
  [ PARTITION BY partition_expression ]
  [ ORDER BY order_list ]
)
```



Railroad diagram of ROW_NUMBER — equivalent to the BNF above

Description

`ROW_NUMBER()` is a window function that displays the number of a given row, starting at one and following the ORDER BY sequence of the window function, with identical values receiving different row numbers. It is similar to the RANK() and DENSE_RANK() functions except that in that function, identical values will receive the same rank for each result.

Examples

The distinction between DENSE_RANK(), RANK() and ROW_NUMBER():

```
CREATE TABLE student(course VARCHAR(10), mark int, name varchar(10));

INSERT INTO student VALUES
  ('Maths', 60, 'Thulile'),
  ('Maths', 60, 'Pritha'),
  ('Maths', 70, 'Voitto'),
  ('Maths', 55, 'Chun'),
  ('Biology', 60, 'Bilal'),
   ('Biology', 70, 'Roger');

SELECT
  RANK() OVER (PARTITION BY course ORDER BY mark DESC) AS rank,
  DENSE_RANK() OVER (PARTITION BY course ORDER BY mark DESC) AS dense_rank,
  ROW_NUMBER() OVER (PARTITION BY course ORDER BY mark DESC) AS row_num,
  course, mark, name
FROM student ORDER BY course, mark DESC;
+------+------------+---------+---------+------+---------+
| rank | dense_rank | row_num | course  | mark | name    |
+------+------------+---------+---------+------+---------+
|    1 |          1 |       1 | Biology |   70 | Roger   |
|    2 |          2 |       2 | Biology |   60 | Bilal   |
|    1 |          1 |       1 | Maths   |   70 | Voitto  |
|    2 |          2 |       2 | Maths   |   60 | Thulile |
|    2 |          2 |       3 | Maths   |   60 | Pritha  |
|    4 |          3 |       4 | Maths   |   55 | Chun    |
+------+------------+---------+---------+------+---------+
```

String Functions

See ASCII.

Return the ASCII value of the first character. This function returns the numeric ASCII code for the leftmost character of the input string.

See BIN.

Return the binary representation of a number. This function converts a number to its binary string equivalent.

See BINARY Operator.

Cast a string to a binary string. This operator converts a character string to a binary string, often used for case-sensitive comparisons.

See BIT_LENGTH.

Return the length of a string in bits. This function calculates the size of the string in bits (length in bytes multiplied by 8).

See CAST.

Complete CAST reference for MariaDB. Complete function guide with syntax, parameters, return values, and usage examples with comprehensive examples and best.

See CHAR Function.

Return the character for each integer passed. This function interprets arguments as integer ASCII values and returns a string of those characters.

See CHAR_LENGTH.

Return the length of a string in characters. This function counts the number of characters in the string, treating multi-byte characters as single units.

See CHARACTER_LENGTH.

Synonym for CHAR_LENGTH(). Returns the number of characters in the string.

See CHR.

Return the character for a specific ASCII value. This function is similar to CHAR() but accepts a single integer argument.

See CONCAT.

Complete CONCAT reference for MariaDB. Complete function guide with syntax, parameters, return values, and usage examples with comprehensive examples and.

See CONCAT_WS.

Concatenate with separator. This function joins strings with a specified separator. It skips NULL values during concatenation.

See CONVERT.

Complete CONVERT() reference: CONVERT(expr,type) and CONVERT(expr USING charset) syntax, SIGNED/UNSIGNED/BINARY/CHAR types, and CAST() differences.

See ELT.

Return the string at a specific index. This function returns the N-th string from a list of arguments.

See EXPORT_SET.

Return a string representation of bits. This function generates a string based on the bits set in a number, using specified ‘on’ and ‘off’ strings.

See EXTRACTVALUE.

Extract a value from XML. This function returns the text content of an XML fragment matching a given XPath expression.

See FIELD.

Return the index of a string in a list. This function returns the position of the first argument within the subsequent list of arguments.

See FIND_IN_SET.

Return the index of a string in a comma-separated list. This function finds the position of a string within a list of strings separated by commas.

See FORMAT.

Format a number. This function formats a number to a format like ‘#,###,###.##’, rounded to a specified number of decimal places.

See FROM_BASE64.

Decode a base-64 encoded string. This function takes a base-64 string and returns the decoded binary result.

See HEX.

Return the hexadecimal representation. This function converts a number or string to its hexadecimal string equivalent.

See INSERT Function.

Insert a substring into a string. This function inserts a string within another string at a specified position and length, replacing existing characters.

See INSTR.

Return the position of the first occurrence of a substring. This function locates a substring within a string and returns its index.

See LCASE.

Synonym for LOWER(). Converts a string to lowercase characters.

See LEFT.

Return the leftmost characters. This function returns the specified number of characters from the beginning (left) of a string.

See LENGTH.

Return the length of a string in bytes. This function counts the number of bytes in the string, which may differ from character count for multi-byte strings.

See LENGTHB.

Return the length of a string in bytes. This function is a synonym for LENGTH() in default mode, returning the byte count.

See LIKE.

Complete LIKE operator reference: LIKE/NOT LIKE pattern matching syntax, % and _ wildcards, ESCAPE clause, NULL behavior, and collation case-sensitivity.

See LOAD_FILE.

Read a file from the server. This function reads the content of a file located on the server host and returns it as a string.

See LOCATE.

Return the position of the first occurrence of a substring. This function finds the starting position of a substring within a string.

See LOWER.

Convert a string to lowercase. This function returns the string with all characters converted to lowercase.

See LPAD.

Left-pad a string. This function pads a string on the left side with a specified string until it reaches a certain length.

See LTRIM.

Remove leading spaces. This function returns the string with any leading whitespace characters removed.

See MAKE_SET.

Return a set of comma-separated strings. This function returns a string consisting of substrings corresponding to the set bits in a given number.

See MATCH AGAINST.

Perform a full-text search. This construct searches for a text query against a set of columns indexed with a FULLTEXT index.

See MID.

Synonym for SUBSTRING(). Returns a substring starting at a specified position for a given length.

See NATURAL_SORT_KEY.

Generate a sort key for natural ordering. This function produces a key that allows strings containing numbers to be sorted in a human-readable order.

See NOT LIKE.

Negated pattern matching. This operator tests whether a string does NOT match a specified SQL pattern.

See NOT REGEXP.

Negated regular expression matching. This operator tests whether a string does NOT match a specified regular expression pattern.

See OCTET_LENGTH.

Return the length of a string in bytes. This function is a synonym for LENGTH() and returns the number of bytes in the string.

See ORD.

Return the numeric value of the first character. This function returns the code for the leftmost character, supporting multi-byte characters.

See POSITION.

Synonym for LOCATE(). Returns the position of the first occurrence of a substring within a string.

See QUOTE.

Quote a string for SQL usage. This function produces a string ready for use as a data value in an SQL statement, escaping special characters.

See REPEAT Function.

Repeat a string. This function returns a string consisting of the input string repeated a specified number of times.

See REPLACE Function.

Complete REPLACE Function reference for MariaDB. Complete function guide with syntax, parameters, return values, and usage examples for production use.

See REVERSE.

Reverse a string. This function returns the string with the order of its characters reversed.

See RIGHT.

Return the rightmost characters. This function returns the specified number of characters from the end (right) of a string.

See RPAD.

Right-pad a string. This function pads a string on the right side with a specified string until it reaches a certain length.

See RTRIM.

Remove trailing spaces. This function returns the string with any trailing whitespace characters removed.

See SFORMAT.

Format strings with arbitrary patterns. This function allows complex string formatting using a pattern string and arguments.

See SOUNDEX.

Return the Soundex string. This function calculates the Soundex key for a string, allowing comparison of words that sound similar.

See SOUNDS LIKE.

Compare strings by sound. This operator tests if two strings have the same Soundex value, useful for fuzzy matching.

See SPACE.

Return a string of spaces. This function returns a string consisting of a specified number of space characters.

See STRCMP.

Compare two strings. This function returns 0 if strings are equal, -1 if the first is smaller, and 1 if the first is larger.

See SUBSTR.

SUBSTR() is a synonym for SUBSTRING(), returning a substring from a string.

See SUBSTRING.

Complete SUBSTRING() reference: syntax forms (pos,len, FROM/FOR), negative position from end, NULL handling, and Oracle sql_mode position 0 behavior.

See SUBSTRING_INDEX.

Complete SUBSTRING_INDEX() reference: SUBSTRING_INDEX(str,delim,count) syntax, positive/negative count, case-sensitive delimiter, NULL rules.

See TO_BASE64.

Encode a string to base-64. This function converts a string argument to its base-64 encoded form.

See TO_CHAR.

Convert to string. This function converts a value (often date/time) to a string, potentially using a format mask.

See TRIM.

Remove spaces from both ends. This function removes leading and trailing whitespace (or other specified characters) from a string.

See TRIM_ORACLE.

Oracle-compatible TRIM function. This version of TRIM provides compatibility with Oracle's syntax for removing characters from a string.

See Type Conversion.

Understand Type Conversion in MariaDB. Learn the rules for implicit conversion during comparisons and arithmetic, and how to use CAST for predictable results.

See UCASE.

Synonym for UPPER(). Converts a string to uppercase characters.

See UNHEX.

Convert hexadecimal to string. This function interprets pairs of hexadecimal digits as numbers and converts them to the characters they represent.

See UPDATEXML.

Replace a portion of XML. This function replaces a section of XML markup matching an XPath expression with a new XML fragment.

See UPPER.

Convert a string to uppercase. This function returns the string with all characters converted to uppercase.

See WEIGHT_STRING.

Return the weight string. This function returns the binary string that represents the sorting and comparison value of the input string.

See Regular Expressions Functions.

Learn about regular expression functions in MariaDB Server. This section details SQL functions for powerful pattern matching and manipulation of string data using regular expressions.

This page is licensed: CC BY-SA / Gnu FDL

ASCII

Syntax

```
ASCII(str)
```

Description

Returns the numeric ASCII value of the leftmost character of the string argument. Returns `0` if the given string is empty and `NULL` if it is `NULL`.

`ASCII()` works for 8-bit characters.

Examples

```
SELECT ASCII(9);
+----------+
| ASCII(9) |
+----------+
|       57 |
+----------+

SELECT ASCII('9');
+------------+
| ASCII('9') |
+------------+
|         57 |
+------------+

SELECT ASCII('abc');
+--------------+
| ASCII('abc') |
+--------------+
|           97 |
+--------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

BIN

Syntax

```
BIN(N)
```

Description

Returns a string representation of the binary value of the given longlong (that is, BIGINT) number. This is equivalent to CONV(N,10,2). The argument should be positive. If it is a `FLOAT`, it will be truncated. Returns `NULL` if the argument is `NULL`.

Examples

```
SELECT BIN(12);
+---------+
| BIN(12) |
+---------+
| 1100    |
+---------+
```

See Also

- Binary literals
- CONV()
- OCT()
- HEX()

This page is licensed: GPLv2, originally from fill_help_tables.sql

BINARY Operator

This page describes the BINARY operator. For details about the data type, see Binary Data Type.

Syntax

```
BINARY
```

Description

The `BINARY` operator casts the string following it to a binary string. This is an easy way to force a column comparison to be done byte by byte rather than character by character. This causes the comparison to be case sensitive even if the column isn't defined as BINARY or BLOB.

`BINARY` also causes trailing spaces to be significant.

Examples

```
SELECT 'a' = 'A';
+-----------+
| 'a' = 'A' |
+-----------+
|         1 |
+-----------+

SELECT BINARY 'a' = 'A';
+------------------+
| BINARY 'a' = 'A' |
+------------------+
|                0 |
+------------------+

SELECT 'a' = 'a ';
+------------+
| 'a' = 'a ' |
+------------+
|          1 |
+------------+

SELECT BINARY 'a' = 'a ';
+-------------------+
| BINARY 'a' = 'a ' |
+-------------------+
|                 0 |
+-------------------+
```

See Also

- Operator Precedence

This page is licensed: GPLv2, originally from fill_help_tables.sql

BIT_LENGTH

Syntax

```
BIT_LENGTH(str)
```

Description

Returns the length of the given string argument in bits. If the argument is not a string, it will be converted to string. If the argument is `NULL`, it returns `NULL`.

Examples

```
SELECT BIT_LENGTH('text');
+--------------------+
| BIT_LENGTH('text') |
+--------------------+
|                 32 |
+--------------------+
```

```
SELECT BIT_LENGTH('');
+----------------+
| BIT_LENGTH('') |
+----------------+
|              0 |
+----------------+
```

Compatibility

PostgreSQL and Sybase support `BIT_LENGTH()`.

This page is licensed: GPLv2, originally from fill_help_tables.sql

CAST

Syntax

```
CAST(expr AS type)
```

Description

The `CAST()` function takes a value of one data type and produces a value of another data type, similar to the CONVERT() function.

The type can be one of the following values:

- BINARY
- CHAR
- DATE
- DATETIME
- DECIMAL
- DOUBLE
- FLOAT
- INTEGER (short for `SIGNED INTEGER`)
- SIGNED [INTEGER]
- UNSIGNED [INTEGER]
- TIME
- VARCHAR
- XMLTYPE (Available starting with MariaDB 12.3)

The main difference between `CAST` and CONVERT() is that CONVERT(expr,type) is ODBC syntax, while `CAST(expr as type)` and CONVERT(… USING …) are SQL92 syntax.

To cast a value to a string data type while specifying the character set, use this extended syntax:

```
CAST(expr AS CHAR CHARACTER SET name)
```

See the examples for casting to character sets.

> **Note:**
>
> Using an introducer like `_utf8mb4'text'` is often more efficient than `CAST('text' AS CHAR CHARACTER SET utf8mb4)`, but `CAST` is necessary when converting data types (like numbers to strings) into a specific encoding. See this example, too.

You can use the `CAST()` function with the `INTERVAL` keyword.

This introduced an incompatibility with previous versions of MariaDB, and all versions of MySQL (see the example below).

Examples

Simple Casts

```
SELECT CAST("abc" AS BINARY);
SELECT CAST("1" AS UNSIGNED INTEGER);
SELECT CAST(123 AS CHAR CHARACTER SET utf8)
```

> **Warning:**
>
> When you casts to CHAR without specifying the character set, the collation_connection character set collation is used. When used with `CHAR CHARACTER SET`, the default collation for that character set is used.

```
SELECT COLLATION(CAST(123 AS CHAR));
+-----------------------------+
| COLLATION(CAST(123 AS CHAR)) |
+-----------------------------+
| latin1_swedish_ci            |
+-----------------------------+

SELECT COLLATION(CAST(123 AS CHAR CHARACTER SET utf8));
+-----------------------------------------------+
| COLLATION(CAST(123 AS CHAR CHARACTER SET utf8)) |
+-----------------------------------------------+
| utf8_general_ci                               |
+-----------------------------------------------+
```

If you also want to change the collation, you have to use the `COLLATE` operator:

```
SELECT COLLATION(CAST(123 AS CHAR CHARACTER SET utf8)
  COLLATE utf8_unicode_ci);
+-------------------------------------------------------------------------+
| COLLATION(CAST(123 AS CHAR CHARACTER SET utf8) COLLATE utf8_unicode_ci) |
+-------------------------------------------------------------------------+
| utf8_unicode_ci                                                         |
+-------------------------------------------------------------------------+
```

Using `CAST()` to order an ENUM field as a CHAR rather than the internal numerical value:

```
CREATE TABLE enum_list (enum_field enum('c','a','b'));

INSERT INTO enum_list (enum_field)
VALUES('c'),('a'),('c'),('b');

SELECT * FROM enum_list
ORDER BY enum_field;
+------------+
| enum_field |
+------------+
| c          |
| c          |
| a          |
| b          |
+------------+

SELECT * FROM enum_list
ORDER BY CAST(enum_field AS CHAR);
+------------+
| enum_field |
+------------+
| a          |
| b          |
| c          |
| c          |
+------------+
```

The following `CAST()` gives warnings, because `x'aa'` and `'X'aa'` don't behave as a number. In all versions of MySQL, no warnings are triggered because they erroneously behave as a number:

```
SELECT CAST(0xAA AS UNSIGNED), CAST(x'aa' AS UNSIGNED), CAST(X'aa' AS UNSIGNED);
+------------------------+-------------------------+-------------------------+
| CAST(0xAA AS UNSIGNED) | CAST(x'aa' AS UNSIGNED) | CAST(X'aa' AS UNSIGNED) |
+------------------------+-------------------------+-------------------------+
|                    170 |                       0 |                       0 |
+------------------------+-------------------------+-------------------------+
1 row in set, 2 warnings (0.00 sec)

Warning (Code 1292): Truncated incorrect INTEGER value: '\xAA'
Warning (Code 1292): Truncated incorrect INTEGER value: '\xAA'
```

Casting to Intervals

```
SELECT CAST(2019-01-04 AS INTERVAL DAY_SECOND(2)) AS "Cast";

+-------------+
| Cast        |
+-------------+
| 00:20:14.00 |
+-------------+
```

Casting to Character Sets

Casting a Literal to a Specific Character Set

```
-- Converts the literal string 'abc' to the utf8mb4 character set
SELECT CAST('abc' AS CHAR CHARACTER SET utf8mb4);
```

Casting a Binary Literal to a Readable Character Set

```
-- Converts a hexadecimal (binary) literal to a UTF-8 string
SELECT CAST(0x68656c6c6f AS CHAR CHARACTER SET utf8mb4);
```

Using an Introducer Inside a CAST

```
-- Telling the parser the input is latin1, then casting the result to utf8mb4
SELECT CAST(_latin1'text' AS CHAR CHARACTER SET utf8mb4);
```

- CONVERT()

This page is licensed: GPLv2, originally from fill_help_tables.sql

CHAR Function

Syntax

```
CHAR(N,... [USING charset_name])
```

Description

`CHAR()` interprets each argument as an INT and returns a string consisting of the characters given by the code values of those integers. `NULL` values are skipped. By default, `CHAR()` returns a binary string. To produce a string in a given character set, use the optional `USING` clause:

```
SELECT CHARSET(CHAR(0x65)), CHARSET(CHAR(0x65 USING utf8));
+--------------------+------------------------------+
| CHARSET(CHAR(0x65)) | CHARSET(CHAR(0x65 USING utf8)) |
+--------------------+------------------------------+
| binary              | utf8                         |
+--------------------+------------------------------+
```

If `USING` is given and the result string is illegal for the given character set, a warning is issued. Also, if strict SQL mode is enabled, the result from `CHAR()` becomes `NULL`.

Examples

```
SELECT CHAR(77,97,114,'105',97,'68',66);
+----------------------------------+
| CHAR(77,97,114,'105',97,'68',66) |
+----------------------------------+
| MariaDB                          |
+----------------------------------+

SELECT CHAR(77,77.3,'77.3');
+----------------------+
| CHAR(77,77.3,'77.3') |
+----------------------+
| MMM                  |
+----------------------+
1 row in set, 1 warning (0.00 sec)

Warning (Code 1292): Truncated incorrect INTEGER value: '77.3'
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

CHAR_LENGTH

Syntax

```
CHAR_LENGTH(str)
CHARACTER_LENGTH(str)
```

Description

Returns the length of the given string argument, measured in characters. A multi-byte character counts as a single character. This means that for a string containing five two-byte characters, LENGTH() (or OCTET_LENGTH() in Oracle mode) returns 10, whereas `CHAR_LENGTH()` returns 5. If the argument is `NULL`, it returns `NULL`.

If the argument is not a string value, it is converted into a string.

It is synonymous with the `CHARACTER_LENGTH()` function.

Examples

```
SELECT CHAR_LENGTH('MariaDB');
+------------------------+
| CHAR_LENGTH('MariaDB') |
+------------------------+
|                      7 |
+------------------------+
```

When Oracle mode is not set:

```
SELECT CHAR_LENGTH('π'), LENGTH('π'), LENGTHB('π'), OCTET_LENGTH('π');
+-------------------+--------------+---------------+--------------------+
| CHAR_LENGTH('π')  | LENGTH('π')  | LENGTHB('π')  | OCTET_LENGTH('π')  |
+-------------------+--------------+---------------+--------------------+
|                 1 |            2 |             2 |                  2 |
+-------------------+--------------+---------------+--------------------+
```

In Oracle mode:

```
SELECT CHAR_LENGTH('π'), LENGTH('π'), LENGTHB('π'), OCTET_LENGTH('π');
+-------------------+--------------+---------------+--------------------+
| CHAR_LENGTH('π')  | LENGTH('π')  | LENGTHB('π')  | OCTET_LENGTH('π')  |
+-------------------+--------------+---------------+--------------------+
|                 1 |            1 |             2 |                  2 |
+-------------------+--------------+---------------+--------------------+
```

CHARACTER_LENGTH

Syntax

```
CHARACTER_LENGTH(str)
```

Description

`CHARACTER_LENGTH()` is a synonym for CHAR_LENGTH().

This page is licensed: GPLv2, originally from fill_help_tables.sql

CHR

Syntax

```
CHR(N)
```

Description

`CHR()` interprets each argument N as an integer and returns a VARCHAR(1) string consisting of the character given by the code values of the integer. The character set and collation of the string are set according to the values of the character_set_database and collation_database system variables.

`CHR()` is similar to the CHAR() function, but only accepts a single argument.

`CHR()` is available in all sql_modes.

Examples

```
SELECT CHR(67);
+---------+
| CHR(67) |
+---------+
| C       |
+---------+

SELECT CHR('67');
+-----------+
| CHR('67') |
+-----------+
| C         |
+-----------+

SELECT CHR('C');
+----------+
| CHR('C') |
+----------+
|          |
+----------+
1 row in set, 1 warning (0.000 sec)

SHOW WARNINGS;
+---------+------+----------------------------------------+
| Level   | Code | Message                                |
+---------+------+----------------------------------------+
| Warning | 1292 | Truncated incorrect INTEGER value: 'C' |
+---------+------+----------------------------------------+
```

CONCAT

Syntax

```
CONCAT(str1,str2,...)
```

Description

Returns the string that results from concatenating the arguments. May have one or more arguments. If all arguments are non-binary strings, the result is a non-binary string. If the arguments include any binary strings, the result is a binary string. A numeric argument is converted to its equivalent binary string form; if you want to avoid that, you can use an explicit type cast, as in this example:

```
SELECT CONCAT(CAST(int_col AS CHAR), char_col);
```

`CONCAT()` returns `NULL` if any argument is `NULL`.

A `NULL` parameter hides all information contained in other parameters from the result. Sometimes this is not desirable; to avoid this, you can:

- Use the CONCAT_WS() function with an empty separator, because that function is `NULL`-safe.
- Use IFNULL() to turn NULLs into empty strings.

Oracle Mode

In Oracle mode, `CONCAT` ignores null.

Examples

```
SELECT CONCAT('Ma', 'ria', 'DB');
+--------------------------+
| CONCAT('Ma', 'ria', 'DB') |
+--------------------------+
| MariaDB                  |
+--------------------------+

SELECT CONCAT('Ma', 'ria', NULL, 'DB');
+---------------------------------+
| CONCAT('Ma', 'ria', NULL, 'DB') |
+---------------------------------+
| NULL                            |
+---------------------------------+

SELECT CONCAT(42.0);
+-------------+
| CONCAT(42.0) |
+-------------+
| 42.0         |
+-------------+
```

Using `IFNULL()` to handle `NULL` values:

```
SELECT CONCAT('The value of @v is: ', IFNULL(@v, ''));
+-----------------------------------------------+
| CONCAT('The value of @v is: ', IFNULL(@v, '')) |
+-----------------------------------------------+
| The value of @v is:                           |
+-----------------------------------------------+
```

In Oracle mode:

```
SELECT CONCAT('Ma', 'ria', NULL, 'DB');
+---------------------------------+
| CONCAT('Ma', 'ria', NULL, 'DB') |
+---------------------------------+
| MariaDB                         |
+---------------------------------+
```

See Also

- GROUP_CONCAT()
- Oracle mode

This page is licensed: GPLv2, originally from fill_help_tables.sql

CONCAT_WS

Syntax

```
CONCAT_WS(separator,str1,str2,...)
```

Description

`CONCAT_WS()` stands for Concatenate With Separator and is a special form of CONCAT(). The first argument is the separator for the rest of the arguments. The separator is added between the strings to be concatenated. The separator can be a string, as can the rest of the arguments.

If the separator is `NULL`, the result is `NULL`; all other `NULL` values are skipped. This makes `CONCAT_WS()` suitable when you want to concatenate some values and avoid losing all information if one of them is `NULL`.

Examples

```
SELECT CONCAT_WS(',','First name','Second name','Last Name');
+------------------------------------------------------+
| CONCAT_WS(',','First name','Second name','Last Name') |
+------------------------------------------------------+
| First name,Second name,Last Name                     |
+------------------------------------------------------+

SELECT CONCAT_WS('-','Floor',NULL,'Room');
+-----------------------------------+
| CONCAT_WS('-','Floor',NULL,'Room') |
+-----------------------------------+
| Floor-Room                        |
+-----------------------------------+
```

In some cases, remember to include a space in the separator string:

```
SET @a = 'gnu', @b = 'penguin', @c = 'sea lion';
Query OK, 0 rows affected (0.00 sec)

SELECT CONCAT_WS(', ', @a, @b, @c);
+-----------------------------+
| CONCAT_WS(', ', @a, @b, @c) |
+-----------------------------+
| gnu, penguin, sea lion      |
+-----------------------------+
```

Using `CONCAT_WS()` to handle `NULL`s:

```
SET @a = 'a', @b = NULL, @c = 'c';

SELECT CONCAT_WS('', @a, @b, @c);
+---------------------------+
| CONCAT_WS('', @a, @b, @c) |
+---------------------------+
| ac                        |
+---------------------------+
```

See Also

- GROUP_CONCAT()

This page is licensed: GPLv2, originally from fill_help_tables.sql

CONVERT

Syntax

```
CONVERT(expr,type), CONVERT(expr USING transcoding_name)
```

Description

The `CONVERT()` and CAST() functions take a value of one type and produce a value of another type.

The type can be one of the following values:

- BINARY
- CHAR
- DATE
- DATETIME
- [DECIMAL (M[,D])]
- DOUBLE
- FLOAT
- INTEGER
  - Short for `SIGNED INTEGER`
- SIGNED [INTEGER]
- UNSIGNED [INTEGER]
- TIME
- VARCHAR (in Oracle mode)

Note that in MariaDB, `INT` and `INTEGER` are the same thing.

`BINARY` produces a string with the BINARY data type. If the optional length is given, `BINARY(N)` causes the cast to use no more than `N` bytes of the argument. Values shorter than the given number in bytes are padded with 0x00

bytes to make them equal the length value.

`CHAR(N)` causes the cast to use no more than the number of characters given in the argument.

The main difference between the CAST() and `CONVERT()` is that `CONVERT(expr,type)` is ODBC syntax while CAST(expr as type) and `CONVERT(... USING ...)` are SQL92 syntax.

`CONVERT()` with `USING` is used to convert data between different character sets. In MariaDB, transcoding names are the same as the corresponding character set names. For example, this statement converts the string 'abc' in the default character set to the corresponding string in the utf8 character set:

```
SELECT CONVERT('abc' USING utf8);
```

Examples

```
SELECT enum_col FROM tbl_name
ORDER BY CAST(enum_col AS CHAR);
```

Converting a BINARY to string to permit the LOWER function to work:

```
SET @x = 'AardVark';

SET @x = BINARY 'AardVark';

SELECT LOWER(@x), LOWER(CONVERT (@x USING latin1));
+-----------+---------------------------------+
| LOWER(@x) | LOWER(CONVERT (@x USING latin1)) |
+-----------+---------------------------------+
| AardVark  | aardvark                        |
+-----------+---------------------------------+
```

See Also

- Character Sets and Collations

This page is licensed: GPLv2, originally from fill_help_tables.sql

ELT

Syntax

```
ELT(N, str1[, str2, str3,...])
```

Description

Takes a numeric argument and a series of string arguments. Returns the string that corresponds to the given numeric position. For instance, it returns `str1` if `N` is 1, `str2` if `N` is 2, and so on. If the numeric argument is a FLOAT, MariaDB rounds it to the nearest INTEGER. If the numeric argument is less than 1, greater than the total number of arguments, or not a number, `ELT()` returns `NULL`. It must have at least two arguments.

It is complementary to the FIELD() function.

Examples

```
SELECT ELT(1, 'ej', 'Heja', 'hej', 'foo');
+-----------------------------------+
| ELT(1, 'ej', 'Heja', 'hej', 'foo') |
+-----------------------------------+
| ej                                |
+-----------------------------------+

SELECT ELT(4, 'ej', 'Heja', 'hej', 'foo');
+-----------------------------------+
| ELT(4, 'ej', 'Heja', 'hej', 'foo') |
+-----------------------------------+
| foo                               |
+-----------------------------------+
```

See also

- FIND_IN_SET() function. Returns the position of a string in a set of strings.
- FIELD() function. Returns the index position of a string in a list.

This page is licensed: GPLv2, originally from fill_help_tables.sql

EXPORT_SET

Syntax

```
EXPORT_SET(bits, on, off[, separator[, number_of_bits]])
```

Description

Takes a minimum of three arguments. Returns a string where each bit in the given `bits` argument is returned, with the string values given for `on` and `off`.

Bits are examined from right to left, (from low-order to high-order bits). Strings are added to the result from left to right, separated by a separator string (defaults as '`,`'). You can optionally limit the number of bits the `EXPORT_SET()` function examines using the `number_of_bits` option.

If any of the arguments are set as `NULL`, the function returns `NULL`.

Examples

```
SELECT EXPORT_SET(5,'Y','N',',',4);
+----------------------------+
| EXPORT_SET(5,'Y','N',',',4) |
+----------------------------+
| Y,N,Y,N                    |
+----------------------------+

SELECT EXPORT_SET(6,'1','0',',',10);
+-----------------------------+
| EXPORT_SET(6,'1','0',',',10) |
+-----------------------------+
| 0,1,1,0,0,0,0,0,0,0          |
+-----------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

EXTRACTVALUE

Syntax

```
EXTRACTVALUE(xml_frag, xpath_expr)
```

Description

The `EXTRACTVALUE()` function takes two string arguments: a fragment of XML markup and an XPath expression, (also known as a locator). It returns the text (That is, CDDATA), of the first text node which is a child of the element or elements matching the XPath expression.

In cases where a valid XPath expression does not match any text nodes in a valid XML fragment, (including the implicit `/text()` expression), the `EXTRACTVALUE()` function returns an empty string.

Invalid Arguments

When either the XML fragment or the XPath expression is `NULL`, the `EXTRACTVALUE()` function returns `NULL`. When the XML fragment is invalid, it raises a warning Code 1525:

```
Warning (Code 1525): Incorrect XML value: 'parse error at line 1 pos 11: unexpected END-OF-INPUT'
```

When the XPath value is invalid, it generates an Error 1105:

```
ERROR 1105 (HY000): XPATH syntax error: ')'
```

Explicit text() Expressions

This function is the equivalent of performing a match using the XPath expression after appending `/text()`. In other words:

```
SELECT
   EXTRACTVALUE('<cases><case>example</case></cases>', '/cases/case')
    AS 'Base Example',
   EXTRACTVALUE('<cases><case>example</case></cases>', '/cases/case/text()')
    AS 'text() Example';
+--------------+----------------+
| Base Example | text() Example |
+--------------+----------------+
| example      | example        |
+--------------+----------------+
```

Count Matches

When `EXTRACTVALUE()` returns multiple matches, it returns the content of the first child text node of each matching element, in the matched order, as a single, space-delimited string.

By design, the `EXTRACTVALUE()` function makes no distinction between a match on an empty element and no match at all. If you need to determine whether no matching element was found in the XML fragment or if an element was found that contained no child text nodes, use the XPath `count()` function.

For instance, when looking for a value that exists, but contains no child text nodes, you would get a count of the number of matching instances:

```
SELECT
   EXTRACTVALUE('<cases><case/></cases>', '/cases/case')
    AS 'Empty Example',
   EXTRACTVALUE('<cases><case/></cases>', 'count(/cases/case)')
    AS 'count() Example';
+---------------+-----------------+
| Empty Example | count() Example |
+---------------+-----------------+
|               |               1 |
+---------------+-----------------+
```

Alternatively, when looking for a value that doesn't exist, `count()` returns 0.

```
SELECT
   EXTRACTVALUE('<cases><case/></cases>', '/cases/person')
    AS 'No Match Example',
   EXTRACTVALUE('<cases><case/></cases>', 'count(/cases/person)')
    AS 'count() Example';
+------------------+-----------------+
| No Match Example | count() Example |
+------------------+-----------------+
|                  |               0|
+------------------+-----------------+
```

Matches

> **Warning:**
>
> **Important**: The `EXTRACTVALUE()` function only returns `CDDATA`. It does not return tags that the element might contain or the text that these child elements contain.

```
SELECT
  EXTRACTVALUE('<cases><case>Person<email>x@example.com</email></case></cases>', '/cases')
   AS Case;
+--------+
| Case   |
+--------+
| Person |
+--------+
```

Note, in the above example, while the XPath expression matches to the parent `<case>` instance, it does not return the contained `<email>` tag or its content.

Examples

```
SELECT
    ExtractValue('<a>ccc<b>ddd</b></a>', '/a')            AS val1,
    ExtractValue('<a>ccc<b>ddd</b></a>', '/a/b')          AS val2,
    ExtractValue('<a>ccc<b>ddd</b></a>', '//b')           AS val3,
    ExtractValue('<a>ccc<b>ddd</b></a>', '/b')            AS val4,
    ExtractValue('<a>ccc<b>ddd</b><b>eee</b></a>', '//b') AS val5;
+------+------+------+------+---------+
| val1 | val2 | val3 | val4 | val5    |
+------+------+------+------+---------+
| ccc  | ddd  | ddd  |      | ddd eee |
+------+------+------+------+---------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

FIELD

Syntax

```
FIELD(pattern, str1[,str2,...])
```

Description

Returns the index position of the string or number matching the given pattern. Returns `0` in the event that none of the arguments match the pattern. Raises an Error 1582 if not given at least two arguments.

When all arguments given to the `FIELD()` function are strings, they are treated as case-insensitive. When all the arguments are numbers, they are treated as numbers. Otherwise, they are treated as doubles.

If the given pattern occurs more than once, the `FIELD()` function only returns the index of the first instance. If the given pattern is `NULL`, the function returns `0`, as a `NULL` pattern always fails to match.

This function is complementary to the ELT() function.

Examples

```
SELECT FIELD('ej', 'Hej', 'ej', 'Heja', 'hej', 'foo')
   AS 'Field Results';
+---------------+
| Field Results |
+---------------+
|             2 |
+---------------+

SELECT FIELD('fo', 'Hej', 'ej', 'Heja', 'hej', 'foo')
   AS 'Field Results';
+---------------+
| Field Results |
+---------------+
|             0 |
+---------------+

SELECT FIELD(1, 2, 3, 4, 5, 1) AS 'Field Results';
+---------------+
| Field Results |
+---------------+
|             5 |
+---------------+

SELECT FIELD(NULL, 2, 3) AS 'Field Results';
+---------------+
| Field Results |
+---------------+
|             0 |
+---------------+

SELECT FIELD('fail') AS 'Field Results';
Error 1582 (42000): Incorrect parameter count in call
to native function 'field'
```

See also

- ELT() function. Returns the N'th element from a set of strings.

This page is licensed: GPLv2, originally from fill_help_tables.sql

FIND_IN_SET

Syntax

```
FIND_IN_SET(pattern, strlist)
```

Description

Returns the index position where the given pattern occurs in a string list. The first argument is the pattern you want to search for. The second argument is a string containing comma-separated variables. If the second argument is of the SET data-type, the function is optimized to use bit arithmetic.

If the pattern does not occur in the string list or if the string list is an empty string, the function returns `0`. If either argument is `NULL`, the function returns `NULL`. The function does not return the correct result if the pattern contains a comma (“`,`”) character.

Examples

```
SELECT FIND_IN_SET('b','a,b,c,d') AS "Found Results";
+---------------+
| Found Results |
+---------------+
|             2 |
+---------------+
```

See Also

- ELT() function. Returns the N’th element from a set of strings.

This page is licensed: GPLv2, originally from fill_help_tables.sql

FORMAT

Syntax

```
FORMAT(num, decimal_position[, locale])
```

Description

Formats the given number for display as a string, adding separators to appropriate position and rounding the results to the given decimal position. For instance, it would format `15233.345` to `15,233.35`.

If the given decimal position is `0`, it rounds to return no decimal point or fractional part. You can optionally specify a locale value to format numbers to the pattern appropriate for the given region.

Examples

```
SELECT FORMAT(1234567890.09876543210, 4) AS 'Format';
+--------------------+
| Format             |
+--------------------+
| 1,234,567,890.0988 |
+--------------------+

SELECT FORMAT(1234567.89, 4) AS 'Format';
+----------------+
| Format         |
+----------------+
| 1,234,567.8900 |
+----------------+

SELECT FORMAT(1234567.89, 0) AS 'Format';
+-----------+
| Format    |
+-----------+
| 1,234,568 |
+-----------+

-- Format number to German number formatting
SELECT FORMAT(123456789,2,'de_DE') AS 'Format';
+----------------+
| Format         |
+----------------+
| 123.456.789,00 |
+----------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

FROM_BASE64

Syntax

```
FROM_BASE64(str)
```

Description

Decodes the given base-64 encode string, returning the result as a binary string. Returns `NULL` if the given string is `NULL` or if it's invalid.

It is the reverse of the TO_BASE64 function.

There are numerous methods to base-64 encode a string. MariaDB uses the following:

- It encodes alphabet value 64 as '`+`'.
- It encodes alphabet value 63 as '`/`'.
- It codes output in groups of four printable characters. Each three byte of data encoded uses four characters. If the final group is incomplete, it pads the difference with the '`=`' character.
- It divides long output, adding a new line very 76 characters.
- In decoding, it recognizes and ignores newlines, carriage returns, tabs and space whitespace characters.

```
SELECT TO_BASE64('Maria') AS 'Input';
+-----------+
| Input     |
+-----------+
| TWFyaWE=  |
+-----------+

SELECT FROM_BASE64('TWFyaWE=') AS 'Output';
+--------+
| Output |
+--------+
| Maria  |
+--------+
```

This page is licensed: CC BY-SA / Gnu FDL

HEX

Syntax

```
HEX(N_or_S)
```

Description

If `N_or_S` is a number, returns a string representation of the hexadecimal value of `N`, where `N` is a `longlong` (BIGINT) number. This is equivalent to CONV(N,10,16).

If `N_or_S` is a string, returns a hexadecimal string representation of `N_or_S` where each byte of each character in `N_or_S` is converted to two hexadecimal digits. If `N_or_S` is `NULL`, returns `NULL`. The inverse of this operation is performed by the UNHEX() function.

`HEX()` with an INET6 argument returns a hexadecimal representation of the underlying 16-byte binary string.

Examples

```
SELECT HEX(255);
+----------+
| HEX(255) |
+----------+
| FF       |
+----------+

SELECT 0x4D617269614442;
+------------------+
| 0x4D617269614442 |
+------------------+
| MariaDB          |
+------------------+

SELECT HEX('MariaDB');
+----------------+
| HEX('MariaDB') |
+----------------+
| 4D617269614442 |
+----------------+
```

```
SELECT HEX(CAST('2001:db8::ff00:42:8329' AS INET6));
+-------------------------------------------+
| HEX(CAST('2001:db8::ff00:42:8329' AS INET6)) |
+-------------------------------------------+
| 20010DB8000000000000FF0000428329            |
+-------------------------------------------+
```

- OCT()

This page is licensed: GPLv2, originally from fill_help_tables.sql

INSERT Function

Syntax

```
INSERT(str,pos,len,newstr)
```

Description

Returns the string `str`, with the substring beginning at position `pos` and `len` characters long replaced by the string `newstr`. Returns the original string if `pos` is not within the length of the string.
Replaces the rest of the string from position `pos` if `len` is not within the length of the rest of the string. Returns `NULL` if any argument is `NULL`.

Examples

```
SELECT INSERT('Quadratic', 3, 4, 'What');
+-----------------------------------+
| INSERT('Quadratic', 3, 4, 'What') |
+-----------------------------------+
| QuWhattic                         |
+-----------------------------------+

SELECT INSERT('Quadratic', -1, 4, 'What');
+-----------------------------------+
| INSERT('Quadratic', -1, 4, 'What') |
+-----------------------------------+
| Quadratic                          |
+-----------------------------------+

SELECT INSERT('Quadratic', 3, 100, 'What');
+-------------------------------------+
| INSERT('Quadratic', 3, 100, 'What') |
+-------------------------------------+
| QuWhat                              |
+-------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

INSTR

Syntax

```
INSTR(str,substr)
```

Description

Returns the position of the first occurrence of substring *substr* in string *str*. This is the same as the two-argument form of LOCATE(), except that the order of the arguments is reversed.

`INSTR()` performs a case-insensitive search.

If any argument is `NULL`, returns `NULL`.

Examples

```
SELECT INSTR('foobarbar', 'bar');
+---------------------------+
| INSTR('foobarbar', 'bar') |
+---------------------------+
|                         4 |
+---------------------------+

SELECT INSTR('My', 'Maria');
+----------------------+
| INSTR('My', 'Maria') |
+----------------------+
|                    0 |
+----------------------+
```

See Also

- LOCATE() ; Returns the position of a string within a string
- SUBSTRING_INDEX() ; Returns the substring from string before count occurrences of a delimiter

This page is licensed: GPLv2, originally from fill_help_tables.sql

LCASE

Syntax

```
LCASE(str)
```

Description

`LCASE()` is a synonym for LOWER().

This page is licensed: GPLv2, originally from fill_help_tables.sql

LEFT

Syntax

```
LEFT(str,len)
```

Description

Returns the leftmost `len` characters from the string `str`, or `NULL` if any argument is `NULL`.

Examples

```
SELECT LEFT('MariaDB', 5);
+--------------------+
| LEFT('MariaDB', 5) |
+--------------------+
| Maria              |
+--------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

LENGTH

Syntax

```
LENGTH(str)
```

Description

Returns the length of the string `str`.

In the default mode, when Oracle mode is not set, the length is measured in bytes. In this case, a multi-byte character counts as multiple bytes. `LENGTH()` returns the length in bytes, whereas `CHAR_LENGTH()` returns the number of characters. This means that, for a string containing five two-byte characters, `LENGTH()` returns 10, whereas CHAR_LENGTH() returns 5. When running Oracle mode, the length is measured in characters, and `LENGTH` is a synonym for CHAR_LENGTH().

If `str` is not a string value, it is converted into a string. If `str` is `NULL`, the function returns `NULL`.

Examples

```
SELECT LENGTH('MariaDB');
+-------------------+
| LENGTH('MariaDB') |
+-------------------+
|                 7 |
+-------------------+
```

When Oracle mode is not set:

```
SELECT CHAR_LENGTH('π'), LENGTH('π'), LENGTHB('π'), OCTET_LENGTH('π');
+-------------------+--------------+---------------+--------------------+
| CHAR_LENGTH('π')  | LENGTH('π')  | LENGTHB('π')  | OCTET_LENGTH('π')  |
+-------------------+--------------+---------------+--------------------+
|                 1 |            2 |             2 |                  2 |
+-------------------+--------------+---------------+--------------------+
```

In Oracle mode:

```
SELECT CHAR_LENGTH('π'), LENGTH('π'), LENGTHB('π'), OCTET_LENGTH('π');
+-------------------+--------------+---------------+--------------------+
| CHAR_LENGTH('π')  | LENGTH('π')  | LENGTHB('π')  | OCTET_LENGTH('π')  |
+-------------------+--------------+---------------+--------------------+
|                 1 |            1 |             2 |                  2 |
+-------------------+--------------+---------------+--------------------+
```

See Also

- CHAR_LENGTH()
- LENGTHB()
- OCTET_LENGTH()
- Oracle mode

This page is licensed: GPLv2, originally from fill_help_tables.sql

LENGTHB

Syntax

```
LENGTHB(str)
```

Description

`LENGTHB()` returns the length of the given string, in bytes. When Oracle mode is not set, this is a synonym for LENGTH.

A multi-byte character counts as multiple bytes. This means that for a string containing five two-byte characters, `LENGTHB()` returns 10, whereas CHAR_LENGTH() returns 5.

If `str` is not a string value, it is converted into a string. If `str` is `NULL`, the function returns `NULL`.

Examples

When Oracle mode is not set:

```
SELECT CHAR_LENGTH('π'), LENGTH('π'), LENGTHB('π'), OCTET_LENGTH('π');
+------------------+--------------+---------------+--------------------+
| CHAR_LENGTH('π')  | LENGTH('π')  | LENGTHB('π')  | OCTET_LENGTH('π')  |
+------------------+--------------+---------------+--------------------+
|                1 |            2 |             2 |                  2 |
+------------------+--------------+---------------+--------------------+
```

In Oracle mode:

```
SELECT CHAR_LENGTH('π'), LENGTH('π'), LENGTHB('π'), OCTET_LENGTH('π');
+------------------+--------------+---------------+--------------------+
| CHAR_LENGTH('π')  | LENGTH('π')  | LENGTHB('π')  | OCTET_LENGTH('π')  |
+------------------+--------------+---------------+--------------------+
|                1 |            1 |             2 |                  2 |
+------------------+--------------+---------------+--------------------+
```

See Also

- CHAR_LENGTH()
- LENGTH()
- OCTET_LENGTH()

LIKE

Syntax

```
expr LIKE pat [ESCAPE 'escape_char']
expr NOT LIKE pat [ESCAPE 'escape_char']
```

Description

Tests whether *expr* matches the pattern *pat*. Returns either 1 (`TRUE`) or 0 (`FALSE`).
Both *expr* and *pat* may be any valid expression and are evaluated to strings.
Patterns may use the following wildcard characters:

- `%` matches any number of characters, including zero.
- `_` matches any single character.

Use `NOT LIKE` to test if a string does not match a pattern. This is equivalent to using the NOT operator on the entire `LIKE` expression.

If either the expression or the pattern is `NULL`, the result is `NULL`.

`LIKE` performs case-insensitive substring matches if the collation for the expression and pattern is case-insensitive. For case-sensitive matches, declare either argument to use a binary collation using collate, or coerce either of them to a BINARY string using CAST. Use SHOW COLLATION to get a list of available collations. Collations ending in `_bin` are case-sensitive.

Numeric arguments are coerced to binary strings.

The `_` wildcard matches a single character, not byte. It will only match a multi-byte character if it is valid in the expression's character set. For example, `_` will match `_utf8"€"`, but it will not match `_latin1"€"` because the Euro sign is not a valid latin1 character. If necessary, use CONVERT to use the expression in a different character set.

If you need to match the characters `_` or `%`, you must escape them. By default, you can prefix the wildcard characters the backslash character `\` to escape them. The backslash is used both to encode special characters like newlines when a string is parsed as well as to escape wildcards in a pattern after parsing. Thus, to match an actual backslash, you sometimes need to double-escape it as `"\``\``\``\"`.

To avoid difficulties with the backslash character, you can change the wildcard escape character using `ESCAPE` in a `LIKE` expression. The argument to `ESCAPE` must be a single-character string.

Examples

Select the days that begin with "T":

```
CREATE TABLE t1 (d VARCHAR(16));
INSERT INTO t1 VALUES
  ("Monday"), ("Tuesday"), ("Wednesday"),
  ("Thursday"), ("Friday"), ("Saturday"), ("Sunday");
SELECT * FROM t1 WHERE d LIKE "T%";
```

```
SELECT * FROM t1 WHERE d LIKE "T%";
+----------+
| d        |
+----------+
| Tuesday  |
| Thursday |
+----------+
```

Select the days that contain the substring "es":

```
SELECT * FROM t1 WHERE d LIKE "%es%";
```

```
SELECT * FROM t1 WHERE d LIKE "%es%";
+-----------+
| d         |
+-----------+
| Tuesday   |
| Wednesday |
+-----------+
```

Select the six-character day names:

```
SELECT * FROM t1 WHERE d like "___day";
```

```
SELECT * FROM t1 WHERE d like "___day";
+---------+
| d       |
+---------+
| Monday  |
| Friday  |
| Sunday  |
+---------+
```

With the default collations, `LIKE` is case-insensitive:

```
SELECT * FROM t1 WHERE d like "t%";
```

```
SELECT * FROM t1 where d like "t%";
+----------+
| d        |
+----------+
| Tuesday  |
| Thursday |
+----------+
```

Use collate to specify a binary collation, forcing case-sensitive matches:

```
SELECT * FROM t1 WHERE d like "t%" COLLATE latin1_bin;
```

```
SELECT * FROM t1 WHERE d like "t%" COLLATE latin1_bin;
Empty SET (0.00 sec)
```

You can include functions and operators in the expression to match. Select dates based on their day name:

```
CREATE TABLE t2 (d DATETIME);
INSERT INTO t2 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
SELECT * FROM t2 WHERE DAYNAME(d) LIKE "T%";
```

```
SELECT * FROM t2 WHERE DAYNAME(d) LIKE "T%";
+------------------+
| d                |
+------------------+
| 2007-01-30 21:31 |
| 2011-04-21 12:34 |
| 2004-10-07 11:19 |
+------------------+
3 rows in set, 7 warnings (0.00 sec)
```

Optimizing LIKE

- MariaDB can use indexes for `LIKE` on string columns in the case where the LIKE doesn't start with `%` or `_`.
- You can set the optimizer_use_condition_selectivity variable to 5. If this is done, then the optimizer will read optimizer_selectivity_sampling_limit rows to calculate the selectivity of the `LIKE` expression before starting to calculate the query plan. This can help speed up some `LIKE` queries by providing the optimizer with more information about your data.

See Also

- For searches on text columns, with results sorted by relevance, see full-text indexes.
- For more complex searches and operations on strings, you can use regular expressions, which were enhanced in MariaDB 10 (see PCRE Regular Expressions).
- Operator Precedence

This page is licensed: GPLv2, originally from fill_help_tables.sql

LOAD_FILE

Syntax

```
LOAD_FILE(file_name)
```

Description

Reads the file and returns the file contents as a string. To use this function, the file must be located on the server host, you must specify the full path name to the file, and you must have the FILE privilege. The file must be readable by all and it must be less than the size, in bytes, of the max_allowed_packet system variable. If the secure_file_priv system variable is set to a non-empty directory name, the file to be loaded must be located in that directory.

If the file does not exist or cannot be read because one of the preceding conditions is not satisfied, the function returns `NULL`.

The character_set_filesystem system variable has controlled interpretation of file names that are given as literal strings.

Statements using the `LOAD_FILE()` function are not safe for statement based replication. This is because the slave will execute the `LOAD_FILE()` command itself. If the file doesn't exist on the slave, the function will return `NULL`.

Examples

```
UPDATE t SET blob_col=LOAD_FILE('/tmp/picture') WHERE id=1;
```

See Also

- SELECT INTO DUMPFILE

This page is licensed: GPLv2, originally from fill_help_tables.sql

LOCATE

Syntax

```
LOCATE(substr,str), LOCATE(substr,str,pos)
```

Description

The first syntax returns the position of the first occurrence of substring `substr` in string `str`. The second syntax returns the position of the first occurrence of substring `substr` in string `str`, starting at position `pos`. Returns 0 if `substr` is not in `str`.

`LOCATE()` performs a case-insensitive search.

If any argument is `NULL`, returns `NULL`.

INSTR() is the same as the two-argument form of `LOCATE()`, except that the order of the arguments is reversed.

Examples

```
SELECT LOCATE('bar', 'foobarbar');
+----------------------------+
| LOCATE('bar', 'foobarbar') |
+----------------------------+
|                          4 |
+----------------------------+

SELECT LOCATE('My', 'Maria');
+-----------------------+
| LOCATE('My', 'Maria') |
+-----------------------+
|                     0 |
+-----------------------+

SELECT LOCATE('bar', 'foobarbar', 5);
+-------------------------------+
| LOCATE('bar', 'foobarbar', 5) |
+-------------------------------+
|                             7 |
+-------------------------------+
```

See Also

- INSTR() ; Returns the position of a string within a string
- SUBSTRING_INDEX() ; Returns the substring from string before count occurrences of a delimiter

This page is licensed: GPLv2, originally from fill_help_tables.sql

LOWER

Syntax

```
LOWER(str)
LCASE(str)
```

Description

Returns the string `str` with all characters changed to lowercase according to the current character set mapping. The default is latin1 (cp1252 West European).

`LCASE` is a synonym for `LOWER` .

Examples

```
SELECT LOWER('QUADRATICALLY');
+------------------------+
| LOWER('QUADRATICALLY') |
+------------------------+
| quadratically          |
+------------------------+
```

`LOWER()` (and UPPER()) are ineffective when applied to binary strings (BINARY, VARBINARY, BLOB). To perform letter case conversion, CONVERT the string to a non-binary string:

```
SET @str = BINARY 'North Carolina';

SELECT LOWER(@str), LOWER(CONVERT(@str USING latin1));
+---------------+----------------------------------+
| LOWER(@str)    | LOWER(CONVERT(@str USING latin1)) |
+---------------+----------------------------------+
| North Carolina | north carolina                    |
+---------------+----------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

LPAD

Syntax

```
LPAD(str, len [,padstr])
```

Description

Returns the string `str`, left-padded with the string `padstr` to a length of `len` characters. If `str` is longer than `len`, the return value is shortened to `len` characters. If `padstr` is omitted, the LPAD function pads spaces.

Returns `NULL` if given a `NULL` argument. If the result is empty (zero length), returns either an empty string or with SQL_MODE=Oracle, `NULL`.

The Oracle mode version of the function can be accessed outside of Oracle mode by using `LPAD_ORACLE` as the function name.

Examples

```
SELECT LPAD('hello',10,'.');
+----------------------+
| LPAD('hello',10,'.') |
+----------------------+
| .....hello           |
+----------------------+

SELECT LPAD('hello',2,'.');
+---------------------+
| LPAD('hello',2,'.') |
+---------------------+
| he                  |
+---------------------+
```

With the pad string defaulting to space:

```
SELECT LPAD('hello',10);
+------------------+
| LPAD('hello',10) |
+------------------+
|      hello       |
+------------------+
```

Oracle mode:

```
SELECT LPAD('',0),LPAD_ORACLE('',0);
+------------+-------------------+
| LPAD('',0) | LPAD_ORACLE('',0) |
+------------+-------------------+
|            | NULL              |
+------------+-------------------+
```

See Also

- RPAD - Right-padding instead of left-padding.

This page is licensed: GPLv2, originally from fill_help_tables.sql

LTRIM

Syntax

```
LTRIM(str)
```

Description

Returns the string `str` with leading space characters removed.

Returns `NULL` if given a `NULL` argument. If the result is empty, returns either an empty string, or with SQL_MODE=Oracle, `NULL`.

The Oracle mode version of the function can be accessed outside of Oracle mode by using `LTRIM_ORACLE` as the function name.

Examples

```
SELECT QUOTE(LTRIM('   MariaDB   '));
+------------------------------+
| QUOTE(LTRIM('   MariaDB   ')) |
+------------------------------+
| 'MariaDB   '                 |
+------------------------------+
```

Oracle mode version:

```
SELECT LTRIM(''),LTRIM_ORACLE('');
+-----------+-----------------+
| LTRIM('') | LTRIM_ORACLE('') |
+-----------+-----------------+
|           | NULL            |
+-----------+-----------------+
```

See Also

- RTRIM - trailing spaces removed
- TRIM - removes all given prefixes or suffixes

This page is licensed: GPLv2, originally from fill_help_tables.sql

MAKE_SET

Syntax

```
MAKE_SET(bits,str1,str2,...)
```

Description

Returns a set value (a string containing substrings separated by “,” characters) consisting of the strings that have the corresponding bit in bits set. `str1` corresponds to bit 0, `str2` to bit 1, and so on. `NULL` values in `str1`, `str2`, … are not appended to the result.

Examples

```
SELECT MAKE_SET(1,'a','b','c');
+------------------------+
| MAKE_SET(1,'a','b','c') |
+------------------------+
| a                      |
+------------------------+

SELECT MAKE_SET(1 | 4,'hello','nice','world');
+--------------------------------------+
| MAKE_SET(1 | 4,'hello','nice','world') |
+--------------------------------------+
| hello,world                          |
+--------------------------------------+

SELECT MAKE_SET(1 | 4,'hello','nice',NULL,'world');
+-------------------------------------------+
| MAKE_SET(1 | 4,'hello','nice',NULL,'world') |
+-------------------------------------------+
| hello                                     |
+-------------------------------------------+

SELECT QUOTE(MAKE_SET(0,'a','b','c'));
+--------------------------------+
| QUOTE(MAKE_SET(0,'a','b','c')) |
+--------------------------------+
| ''                             |
+--------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

MATCH AGAINST

Syntax

```
MATCH (col1,col2,...) AGAINST (expr [search_modifier])
```

Description

A special construct used to perform a fulltext search on a fulltext index.

See Fulltext Index Overview for a full description, and Full-text Indexes for more articles on the topic.

Examples

```
CREATE TABLE ft_myisam(copy TEXT,FULLTEXT(copy)) ENGINE=MyISAM;

INSERT INTO ft_myisam(copy) VALUES ('Once upon a time'), ('There was a wicked witch'),
 ('Who ate everybody up');

SELECT * FROM ft_myisam WHERE MATCH(copy) AGAINST('wicked');
+--------------------------+
| copy                     |
+--------------------------+
| There was a wicked witch |
+--------------------------+
```

```
SELECT id, body, MATCH (title,body) AGAINST
    ('Security implications of running MySQL as root'
    IN NATURAL LANGUAGE MODE) AS score
    FROM articles WHERE MATCH (title,body) AGAINST
    ('Security implications of running MySQL as root'
    IN NATURAL LANGUAGE MODE);
+----+-------------------------------------+-----------------+
| id | body                                | score           |
+----+-------------------------------------+-----------------+
|  4 | 1. Never run mysqld as root. 2. ... | 1.5219271183014 |
|  6 | When configured properly, MySQL ... | 1.3114095926285 |
+----+-------------------------------------+-----------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

MID

Syntax

```
MID(str,pos,len)
```

Description

MID(str,pos,len) is a synonym for SUBSTRING(str,pos,len)!

Examples

```
SELECT MID('abcd',4,1);
+-----------------+
| MID('abcd',4,1) |
+-----------------+
| d               |
+-----------------+

SELECT MID('abcd',2,2);
+-----------------+
| MID('abcd',2,2) |
+-----------------+
| bc              |
+-----------------+
```

A negative starting position:

```
SELECT MID('abcd',-2,4);
+------------------+
| MID('abcd',-2,4) |
+------------------+
| cd               |
+------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

NATURAL_SORT_KEY

Note:

`NATURAL_SORT_KEY` is available from MariaDB 10.7.

Syntax

```
NATURAL_SORT_KEY(str)
```

Description

The `NATURAL_SORT_KEY` function is used for sorting that is closer to natural sorting. Strings are sorted in alphabetical order, while numbers are treated in a way such that, for example, `10` is greater than `2`, whereas in other forms of sorting, `2` would be greater than `10`, just like `z` is greater than `ya`.

There are multiple natural sort implementations, differing in the way they handle leading zeroes, fractions, i18n, negatives, decimals and so on.

MariaDB's implementation ignores leading zeroes when performing the sort.

You can use also use `NATURAL_SORT_KEY` with generated columns. The value is not stored permanently in the table. When using a generated column, the virtual column must be longer than the base column to cater for embedded numbers in the string and MDEV-24582.

Examples

Strings and Numbers

```
CREATE TABLE t1 (c TEXT);

INSERT INTO t1 VALUES ('b1'),('a2'),('a11'),('a1');

SELECT c FROM t1;
+------+
| c    |
+------+
| b1   |
| a2   |
| a11  |
| a1   |
+------+

SELECT c FROM t1 ORDER BY c;
+------+
| c    |
+------+
| a1   |
| a11  |
| a2   |
| b1   |
+------+
```

Unsorted, regular sort and natural sort:

```
TRUNCATE t1;

INSERT INTO t1 VALUES
  ('5.5.31'),('10.7.0'),('10.2.1'),
  ('10.1.22'),('10.3.32'),('10.2.12');

SELECT c FROM t1;
+---------+
| c       |
+---------+
| 5.5.31  |
| 10.7.0  |
| 10.2.1  |
| 10.1.22 |
| 10.3.32 |
| 10.2.12 |
+---------+

SELECT c FROM t1 ORDER BY c;
+---------+
| c       |
+---------+
| 10.1.22 |
| 10.2.1  |
| 10.2.12 |
| 10.3.32 |
| 10.7.0  |
| 5.5.31  |
+---------+

SELECT c FROM t1 ORDER BY NATURAL_SORT_KEY(c);
+---------+
| c       |
+---------+
| 5.5.31  |
| 10.1.22 |
| 10.2.1  |
| 10.2.12 |
| 10.3.32 |
| 10.7.0  |
+---------+
```

IPs

Sorting IPs, unsorted, regular sort and natural sort::

```
TRUNCATE t1;

INSERT INTO t1 VALUES
  ('192.167.3.1'),('192.167.1.12'),('100.200.300.400'),
  ('100.50.60.70'),('100.8.9.9'),('127.0.0.1'),('0.0.0.0');

SELECT c FROM t1;
+-----------------+
| c               |
+-----------------+
| 192.167.3.1     |
| 192.167.1.12    |
| 100.200.300.400 |
| 100.50.60.70    |
| 100.8.9.9       |
| 127.0.0.1       |
| 0.0.0.0         |
+-----------------+

SELECT c FROM t1 ORDER BY c;
+-----------------+
| c               |
+-----------------+
| 0.0.0.0         |
| 100.200.300.400 |
| 100.50.60.70    |
| 100.8.9.9       |
| 127.0.0.1       |
| 192.167.1.12    |
| 192.167.3.1     |
+-----------------+

SELECT c FROM t1 ORDER BY NATURAL_SORT_KEY(c);
+-----------------+
| c               |
+-----------------+
| 0.0.0.0         |
| 100.8.9.9       |
| 100.50.60.70    |
| 100.200.300.400 |
| 127.0.0.1       |
| 192.167.1.12    |
| 192.167.3.1     |
+-----------------+
```

Generated Columns

Using with a generated column:

```
CREATE TABLE t(c VARCHAR(3), k VARCHAR(4) AS (NATURAL_SORT_KEY(c)) INVISIBLE);

INSERT INTO t(c) VALUES ('b1'),('a2'),('a11'),('a10');

SELECT * FROM t ORDER by k;
+------+
| c    |
+------+
| a2   |
| a10  |
| a11  |
| b1   |
+------+
```

Note that if the virtual column is not longer, results may not be as expected:

```
CREATE TABLE t2(c VARCHAR(3), k VARCHAR(3) AS (NATURAL_SORT_KEY(c)) INVISIBLE);

INSERT INTO t2(c) VALUES ('b1'),('a2'),('a11'),('a10');

SELECT * FROM t2 ORDER by k;
+------+
| c    |
+------+
| a2   |
| a11  |
| a10  |
| b1   |
+------+
```

Leading Zeroes

Ignoring leading zeroes can lead to undesirable results in certain contexts. For example:

```
CREATE TABLE t3 (a VARCHAR(4));

INSERT INTO t3 VALUES
  ('a1'), ('a001'), ('a10'), ('a001'), ('a10'),
  ('a01'), ('a01'), ('a01b'), ('a01b'), ('a1');

SELECT a FROM t3 ORDER BY a;
+------+
| a    |
+------+
| a001 |
| a001 |
| a01  |
| a01  |
| a01b |
| a01b |
| a1   |
| a1   |
| a10  |
| a10  |
+------+
10 rows in set (0.000 sec)

SELECT a FROM t3 ORDER BY NATURAL_SORT_KEY(a);
+------+
| a    |
+------+
| a1   |
| a01  |
| a01  |
| a001 |
| a001 |
| a1   |
| a01b |
| a01b |
| a10  |
| a10  |
+------+
```

This may not be what we were hoping for in a ‘natural’ sort. A workaround is to sort by both `NATURAL_SORT_KEY` and regular sort.

```
SELECT a FROM t3 ORDER BY NATURAL_SORT_KEY(a), a;
+------+
| a    |
+------+
| a001 |
| a001 |
| a01  |
| a01  |
| a1   |
| a1   |
| a01b |
| a01b |
| a10  |
| a10  |
+------+
```

This page is licensed: CC BY-SA / Gnu FDL

NOT LIKE

Syntax

```
expr NOT LIKE pat [ESCAPE 'escape_char']
```

Description

This is the same as NOT (expr LIKE pat [ESCAPE 'escape_char']).

This page is licensed: GPLv2, originally from fill_help_tables.sql

NOT REGEXP

Syntax

```
expr NOT REGEXP pat, expr NOT RLIKE pat
```

Description

This is the same as NOT (expr REGEXP pat).

This page is licensed: GPLv2, originally from fill_help_tables.sql

OCTET_LENGTH

Syntax

```
OCTET_LENGTH(str)
```

Description

`OCTET_LENGTH()` returns the length of the given string, in octets (bytes). This is a synonym for LENGTHB(), and, when Oracle mode is not set, a synonym for LENGTH().

A multi-byte character counts as multiple bytes. This means that for a string containing five two-byte characters, `OCTET_LENGTH()` returns 10, whereas CHAR_LENGTH() returns 5.

If `str` is not a string value, it is converted into a string. If `str` is `NULL`, the function returns `NULL`.

Examples

When Oracle mode is not set:

```
SELECT CHAR_LENGTH('π'), LENGTH('π'), LENGTHB('π'), OCTET_LENGTH('π');
+------------------+--------------+---------------+--------------------+
| CHAR_LENGTH('π')  | LENGTH('π')  | LENGTHB('π')  | OCTET_LENGTH('π')  |
+------------------+--------------+---------------+--------------------+
|                1 |            2 |             2 |                  2 |
+------------------+--------------+---------------+--------------------+
```

In Oracle mode:

```
SELECT CHAR_LENGTH('π'), LENGTH('π'), LENGTHB('π'), OCTET_LENGTH('π');
+------------------+--------------+---------------+--------------------+
| CHAR_LENGTH('π')  | LENGTH('π')  | LENGTHB('π')  | OCTET_LENGTH('π')  |
+------------------+--------------+---------------+--------------------+
|                1 |            1 |             2 |                  2 |
+------------------+--------------+---------------+--------------------+
```

See Also

- CHAR_LENGTH()
- LENGTH()
- LENGTHB()
- Oracle mode

This page is licensed: GPLv2, originally from fill_help_tables.sql

ORD

Syntax

```
ORD(str)
```

Description

If the leftmost character of the string `str` is a multi-byte character, returns the code for that character, calculated from the numeric values of its constituent bytes using this formula:

```
(1st byte code)
+ (2nd byte code x 256)
+ (3rd byte code x 256 x 256) ...
```

If the leftmost character is not a multi-byte character, `ORD()` returns the same value as the ASCII() function.

Examples

```
SELECT ORD('2');
+----------+
| ORD('2') |
+----------+
|       50 |
+----------+
```

See Also

- ASCII() - Return ASCII value of first character
- CHAR() - Create a character from an integer value

This page is licensed: GPLv2, originally from fill_help_tables.sql

POSITION

Syntax

```
POSITION(substr IN str)
```

Description

`POSITION(substr IN str)` is a synonym for LOCATE(substr,str).

The function is part of ODBC 3.0.

This page is licensed: GPLv2, originally from fill_help_tables.sql

QUOTE

Syntax

```
QUOTE(str)
```

Description

Quotes a string to produce a result that can be used as a properly escaped data value in an SQL statement. The string is returned enclosed by single quotes and with each instance of single quote (“ `'` ”), backslash (“ `\` ”), `ASCII NUL`, and Control-Z preceded by a backslash. If the argument is `NULL`, the return value is the word “ `NULL` ” without enclosing single quotes.

Examples

```
SELECT QUOTE("Don't!");
+-----------------+
| QUOTE("Don't!") |
+-----------------+
| 'Don\'t!'       |
+-----------------+

SELECT QUOTE(NULL);
+-------------+
| QUOTE(NULL) |
+-------------+
| NULL        |
+-------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

REPEAT Function

Syntax

```
REPEAT(str,count)
```

Description

Returns a string consisting of the string `str` repeated `count` times. If `count` is less than 1, returns an empty string. Returns NULL if `str` or `count` are `NULL`.

Examples

```
SELECT QUOTE(REPEAT('MariaDB ',4));
+-----------------------------------+
| QUOTE(REPEAT('MariaDB ',4))       |
+-----------------------------------+
| 'MariaDB MariaDB MariaDB MariaDB ' |
+-----------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

REPLACE Function

Syntax

```
REPLACE(str,from_str,to_str)
```

Description

Returns the string `str` with all occurrences of the string `from_str` replaced by the string `to_str`. `REPLACE()` performs a case-sensitive match when searching for `from_str`. If any argument is `NULL`, the function returns `NULL`.

Examples

```
SELECT REPLACE('www.mariadb.org', 'w', 'Ww');
+---------------------------------------+
| REPLACE('www.mariadb.org', 'w', 'Ww') |
+---------------------------------------+
| WwWwWw.mariadb.org                    |
+---------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

REVERSE

Syntax

```
REVERSE(str)
```

Description

Returns the string `str` with the order of the characters reversed. If the input string is `NULL`, the function returns `NULL`. ##### Examples

```
SELECT REVERSE('desserts');
+--------------------+
| REVERSE('desserts') |
+--------------------+
| stressed           |
+--------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

RIGHT

Syntax

```
RIGHT(str,len)
```

Description

Returns the rightmost *`len`* characters from the string *`str`*, or `NULL` if any argument is `NULL`.

Examples

```
SELECT RIGHT('MariaDB', 2);
+--------------------+
| RIGHT('MariaDB', 2) |
+--------------------+
| DB                 |
+--------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

RPAD

Syntax

```
RPAD(str, len [, padstr])
```

Description

Returns the string `str`, right-padded with the string `padstr` to a length of `len` characters. If `str` is longer than `len`, the return value is shortened to `len` characters. If `padstr` is omitted, the RPAD function pads spaces.

Returns `NULL` if given a `NULL` argument. If the result is empty (a length of zero), returns either an empty string, or, with SQL_MODE=Oracle, `NULL`.

The Oracle mode version of the function can be accessed outside of Oracle mode by using `RPAD_ORACLE` as the function name.

Examples

```
SELECT RPAD('hello',10,'.');
+----------------------+
| RPAD('hello',10,'.') |
+----------------------+
| hello.....           |
+----------------------+

SELECT RPAD('hello',2,'.');
+--------------------+
| RPAD('hello',2,'.') |
+--------------------+
| he                 |
+--------------------+
```

With the pad string defaulting to space:

```
SELECT RPAD('hello',30);
+--------------------------------+
| RPAD('hello',30)               |
+--------------------------------+
| hello                          |
+--------------------------------+
```

Oracle mode:

```
SELECT RPAD('',0),RPAD_ORACLE('',0);
+------------+-------------------+
| RPAD('',0) | RPAD_ORACLE('',0) |
+------------+-------------------+
|            | NULL              |
+------------+-------------------+
```

See Also

- LPAD - Left-padding instead of right-padding.

This page is licensed: GPLv2, originally from fill_help_tables.sql

RTRIM

Syntax

```
RTRIM(str)
```

Description

Returns the string `str` with trailing space characters removed.

Returns NULL if given a NULL argument. If the result is empty, returns either an empty string, or, with SQL_MODE=Oracle, `NULL`.

The Oracle mode version of the function can be accessed outside of Oracle mode by using `RTRIM_ORACLE` as the function name.

Examples

```
SELECT QUOTE(RTRIM('MariaDB    '));
+-----------------------------+
| QUOTE(RTRIM('MariaDB    ')) |
+-----------------------------+
| 'MariaDB'                   |
+-----------------------------+
```

Oracle mode:

```
SELECT RTRIM(''),RTRIM_ORACLE('');
+-----------+------------------+
| RTRIM('') | RTRIM_ORACLE('') |
+-----------+------------------+
|           | NULL             |
+-----------+------------------+
```

See Also

- LTRIM - leading spaces removed
- TRIM - removes all given prefixes or suffixes

This page is licensed: GPLv2, originally from fill_help_tables.sql

SFORMAT

> **Note:**
>
> `SFORMAT` is available from MariaDB 10.7.

Description

The `SFORMAT` function takes an input string and a formatting specification and returns the string formatted using the rules the user passed in the specification.

It uses the fmtlib library for Python-like (as well as Rust, C++20, etc) string formatting.

Only fmtlib 7.0.0+ is supported.

There is no native support for temporal and decimal values:

- `TIME_RESULT` is handled as `STRING_RESULT`.
- `DECIMAL_RESULT` is handled as `REAL_RESULT`.

Examples

```
SELECT SFORMAT("The answer is {}.", 42);
+---------------------------------+
| SFORMAT("The answer is {}.", 42) |
+---------------------------------+
| The answer is 42.               |
+---------------------------------+

CREATE TABLE test_sformat(mdb_release char(6), mdev int, feature char(20));

INSERT INTO test_sformat VALUES('10.7.0', 25015, 'Python style sformat'),
  ('10.7.0', 4958, 'UUID');

SELECT * FROM test_sformat;
+-------------+-------+----------------------+
| mdb_release | mdev  | feature              |
+-------------+-------+----------------------+
| 10.7.0      | 25015 | Python style sformat |
| 10.7.0      |  4958 | UUID                 |
+-------------+-------+----------------------+

SELECT SFORMAT('MariaDB Server {} has a preview for MDEV-{} which is about {}',
  mdb_release, mdev, feature) AS 'Preview Release Examples'
  FROM test_sformat;
+-----------------------------------------------------------------------------------------+
| Preview Release Examples                                                                |
+-----------------------------------------------------------------------------------------+
| MariaDB Server 10.7.0 has a preview for MDEV-25015 which is about Python style sformat |
| MariaDB Server 10.7.0 has a preview for MDEV-4958 which is about UUID                   |
+-----------------------------------------------------------------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

SOUNDEX

Syntax

```
SOUNDEX(str)
```

Description

Returns a soundex string from *str*. Two strings that sound almost the same should have identical soundex strings. A standard soundex string is four characters long, but the `SOUNDEX()` function returns an arbitrarily long string. You can use `SUBSTRING()` on the result to get a standard soundex string. All non-alphabetic characters in *str* are ignored. All international alphabetic characters outside the A-Z range are treated as vowels.

Important: When using `SOUNDEX()`, you should be aware of the following details:

- This function, as currently implemented, is intended to work well with strings that are in the English language only. Strings in other languages may not produce reasonable results.
- This function implements the original Soundex algorithm, not the more popular enhanced version (also described by D. Knuth). The difference is that original version discards vowels first and duplicates second, whereas the enhanced version discards duplicates first and vowels second.

Examples

```
SOUNDEX('Hello');
+------------------+
| SOUNDEX('Hello') |
+------------------+
| H400             |
+------------------+
```

```
SELECT SOUNDEX('MariaDB');
+--------------------+
| SOUNDEX('MariaDB') |
+--------------------+
| M631               |
+--------------------+
```

```
SELECT SOUNDEX('Knowledgebase');
+--------------------------+
| SOUNDEX('Knowledgebase') |
+--------------------------+
| K543212                  |
+--------------------------+
```

```
SELECT givenname, surname FROM users WHERE SOUNDEX(givenname) = SOUNDEX("robert");
+-----------+---------+
| givenname | surname |
+-----------+---------+
| Roberto   | Castro  |
+-----------+---------+
```

See Also

- SOUNDS LIKE()

This page is licensed: GPLv2, originally from fill_help_tables.sql

SOUNDS LIKE

Syntax

```
expr1 SOUNDS LIKE expr2
```

Description

This is the same as SOUNDEX(expr1) = `SOUNDEX(expr2)`.

Example

```
SELECT givenname, surname FROM users WHERE givenname SOUNDS LIKE "robert";
+-----------+---------+
| givenname | surname |
+-----------+---------+
| Roberto   | Castro  |
+-----------+---------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

SPACE

Syntax

```
SPACE(N)
```

Description

Returns a string consisting of `N` space characters. If `N` is `NULL`, returns `NULL`.

Examples

```
SELECT QUOTE(SPACE(6));
+-----------------+
| QUOTE(SPACE(6)) |
+-----------------+
| '      '        |
+-----------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

STRCMP

Syntax

```
STRCMP(expr1,expr2)
```

Description

`STRCMP()` returns `0` if the strings are the same, `-1` if the first argument is smaller than the second according to the current sort order, and `1` if the strings are otherwise not the same. Returns `NULL` is either argument is `NULL`.

Examples

```
SELECT STRCMP('text', 'text2');
+-------------------------+
| STRCMP('text', 'text2') |
+-------------------------+
|                      -1 |
+-------------------------+

SELECT STRCMP('text2', 'text');
+-------------------------+
| STRCMP('text2', 'text') |
+-------------------------+
|                       1 |
+-------------------------+

SELECT STRCMP('text', 'text');
+------------------------+
| STRCMP('text', 'text') |
+------------------------+
|                      0 |
+------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

SUBSTR

Description

`SUBSTR()` is a synonym for SUBSTRING().

This page is licensed: GPLv2, originally from fill_help_tables.sql

SUBSTRING

Syntax

```
SUBSTRING(str,pos),
SUBSTRING(str FROM pos),
SUBSTRING(str,pos,len),
SUBSTRING(str FROM pos FOR len)

SUBSTR(str,pos),
SUBSTR(str FROM pos),
SUBSTR(str,pos,len),
SUBSTR(str FROM pos FOR len)
```

Description

The forms without a *`len`* argument return a substring from string *`str`* starting at position *`pos`*.

The forms with a *`len`* argument return a substring *`len`* characters long from string *`str`*, starting at position *`pos`*.

The forms that use *`FROM`* are standard SQL syntax.

It is also possible to use a negative value for *`pos`*. In this case, the beginning of the substring is *`pos`* characters from the end of the string, rather than the beginning. A negative value may be used for *`pos`* in any of the forms of this function.

By default, the position of the first character in the string from which the substring is to be extracted is 1. If the value of *pos* is 0, the result is empty string. For Oracle compatibility, when `sql_mode` is set to '`oracle`', position 0 is treated as position 1.

If any argument is `NULL`, returns `NULL`.

> **CURRENT**
>
> The optimizer can make use of an index for conditions like `SUBSTR(indexed_column, 1, n) = const_string`.
>
> **< 11.8**
>
> The optimizer cannot make use of an index if an indexed column is an argument of `SUBSTR()`.

Examples

```
SELECT SUBSTRING('Knowledgebase',5);
+-----------------------------+
| SUBSTRING('Knowledgebase',5) |
+-----------------------------+
| ledgebase                   |
+-----------------------------+

SELECT SUBSTRING('MariaDB' FROM 6);
+----------------------------+
| SUBSTRING('MariaDB' FROM 6) |
+----------------------------+
| DB                         |
+----------------------------+

SELECT SUBSTRING('Knowledgebase',3,7);
+-------------------------------+
| SUBSTRING('Knowledgebase',3,7) |
+-------------------------------+
| owledge                       |
+-------------------------------+

SELECT SUBSTRING('Knowledgebase', -4);
+--------------------------------+
| SUBSTRING('Knowledgebase', -4) |
+--------------------------------+
| base                           |
+--------------------------------+

SELECT SUBSTRING('Knowledgebase', 0);
+--------------------------------+
| SUBSTRING('Knowledgebase', 0)  |
+--------------------------------+
|                                |
+--------------------------------+

SELECT SUBSTRING('Knowledgebase', -8, 4);
+-----------------------------------+
| SUBSTRING('Knowledgebase', -8, 4) |
+-----------------------------------+
| edge                              |
+-----------------------------------+

SELECT SUBSTRING('Knowledgebase' FROM -8 FOR 4);
+-----------------------------------------+
| SUBSTRING('Knowledgebase' FROM -8 FOR 4) |
+-----------------------------------------+
| edge                                    |
+-----------------------------------------+
```

Oracle mode:

```
SELECT SUBSTR('abc',1,2);
+------------------+
| SUBSTR('abc',1,2) |
+------------------+
| ab                |
+------------------+

SET sql_mode='oracle';

SELECT SUBSTR('abc',0,3);
+------------------+
| SUBSTR('abc',0,3) |
+------------------+
| abc               |
+------------------+

SELECT SUBSTR('abc',1,2);
+------------------+
| SUBSTR('abc',1,2) |
+------------------+
| ab                |
+------------------+
```

See Also

- INSTR() - Returns the position of a string within a string
- LOCATE() - Returns the position of a string within a string
- SUBSTRING_INDEX() - Returns a string based on substring

This page is licensed: GPLv2, originally from fill_help_tables.sql

SUBSTRING_INDEX

Syntax

```
SUBSTRING_INDEX(str,delim,count)
```

Description

Returns the substring from string *`str`* before count occurrences of the delimiter *`delim`*. If *`count`* is positive, everything to the left of the final delimiter (counting from the left) is returned. If *`count`* is negative, everything to the right of the final delimiter (counting from the right) is returned. `SUBSTRING_INDEX()` performs a case-sensitive match when searching for *`delim`*.

If any argument is `NULL`, returns `NULL`.

For example:

```
SUBSTRING_INDEX('www.mariadb.org', '.', 2)
```

It means “Return all of the characters up to the 2nd occurrence of .”

Examples

```
SELECT SUBSTRING_INDEX('www.mariadb.org', '.', 2);
+--------------------------------------------+
| SUBSTRING_INDEX('www.mariadb.org', '.', 2) |
+--------------------------------------------+
| www.mariadb                                |
+--------------------------------------------+

SELECT SUBSTRING_INDEX('www.mariadb.org', '.', -2);
+---------------------------------------------+
| SUBSTRING_INDEX('www.mariadb.org', '.', -2) |
+---------------------------------------------+
| mariadb.org                                 |
+---------------------------------------------+
```

See Also

- INSTR() - Returns the position of a string within a string
- LOCATE() - Returns the position of a string within a string
- SUBSTRING() - Returns a string based on position

This page is licensed: GPLv2, originally from fill_help_tables.sql

TO_BASE64

Syntax

```
TO_BASE64(str)
```

Description

Converts the string argument `str` to its base-64 encoded form, returning the result as a character string in the connection character set and collation.

The argument `str` will be converted to string first if it is not a string. A `NULL` argument will return a `NULL` result.

The reverse function, FROM_BASE64(), decodes an encoded base-64 string.

There are a numerous different methods to base-64 encode a string. The following are used by MariaDB and MySQL:

- Alphabet value 64 is encoded as '+'.
- Alphabet value 63 is encoded as '/'.
- Encoding output is made up of groups of four printable characters, with each three bytes of data encoded using four characters. If the final group is not complete, it is padded with '=' characters to make up a length of four.
- To divide long output, a newline is added after every 76 characters.
- Decoding will recognize and ignore newlines, carriage returns, tabs, and spaces.

Examples

```
SELECT TO_BASE64('Maria');
+--------------------+
| TO_BASE64('Maria') |
+--------------------+
| TWFyaWE=           |
+--------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

TO_CHAR

> **Note:**
>
> `TO_CHAR` is available from MariaDB 10.6.

Syntax

```
TO_CHAR(expr[, fmt])
```

Description

CURRENT

The `TO_CHAR` function converts an *expr* of type date, datetime, time or timestamp to a string. The optional *fmt* argument supports `YYY/YYYY/YY/RRRR/RR/MM/MON/MONTH/MI/DD/DY/HH/HH12/HH24/SS` and special characters. The default value is `YYYY-MM-DD HH24:MI:SS`. `TO_CHAR` also accepts `FM` in the format string, which disables padding of all components following it.

`FM` can be specified multiple times, with each time disabling the previous state:

- An odd number of `FM`s disables padding.
- An even number of `FM`s enables padding.

These additional formats (for *`fmt`*) are available:

- `FF[1-6]` – Fractional seconds
- `DDD` – Day (1-366)
- `IW` – Week 1-53 according to ISO 8601
- `I` – 1-digit year according to ISO 8601
- `IY` – 2-digit year according to ISO 8601
- `IYY` – 3-digit year according to ISO 8601
- `IYYY` – 4-digit year according to ISO 8601
- `SYYY` – 4-digit year according to ISO 8601 (Oracle can use signed years)

< 12.3

The `TO_CHAR` function converts an *expr* of type date, datetime, time or timestamp to a string. The optional *fmt* argument supports `YYY/YYYY/YY/RRRR/RR/MM/MON/MONTH/MI/DD/DY/HH/HH12/HH24/SS` and special characters. The default value is `YYYY-MM-DD HH24:MI:SS`. `TO_CHAR` also accepts `FM` in the format string, which disables padding of all components following it.

`FM` can be specified multiple times, with each time disabling the previous state:

- An odd number of `FM`s disables padding.
- An even number of `FM`s enables padding.

< 12.0

The `TO_CHAR` function converts an *expr* of type date, datetime, time or timestamp to a string. The optional *`fmt`* argument supports `YYY/YYYY/YY/RRRR/RR/MM/MON/MONTH/MI/DD/DY/HH/HH12/HH24/SS` and special characters. The default value is `YYYY-MM-DD HH24:MI:SS`.

In Oracle, `TO_CHAR` can also be used to convert numbers to strings, but this is not supported in MariaDB and gives an error.

Examples

CURRENT

```
SELECT TO_CHAR('1980-01-11 04:50:39', 'YYYY-MM-DD');
+-------------------------------------------+
| TO_CHAR('1980-01-11 04:50:39', 'YYYY-MM-DD') |
+-------------------------------------------+
| 1980-01-11                                |
+-------------------------------------------+

SELECT TO_CHAR('1980-01-11 04:50:39', 'HH24-MI-SS');
+-------------------------------------------+
| TO_CHAR('1980-01-11 04:50:39', 'HH24-MI-SS') |
+-------------------------------------------+
| 04-50-39                                  |
+-------------------------------------------+

SELECT TO_CHAR('00-01-01 00:00:00', 'YY-MM-DD HH24:MI:SS');
+-----------------------------------------------------+
| TO_CHAR('00-01-01 00:00:00', 'YY-MM-DD HH24:MI:SS') |
+-----------------------------------------------------+
| 00-01-01 00:00:00                                   |

SELECT TO_CHAR('99-12-31 23:59:59', 'YY-MM-DD HH24:MI:SS');
+-----------------------------------------------------+
| TO_CHAR('99-12-31 23:59:59', 'YY-MM-DD HH24:MI:SS') |
+-----------------------------------------------------+
| 99-12-31 23:59:59                                   |
+-----------------------------------------------------+

SELECT TO_CHAR('9999-12-31 23:59:59', 'YY-MM-DD HH24:MI:SS');
+-----------------------------------------------------+
| TO_CHAR('9999-12-31 23:59:59', 'YY-MM-DD HH24:MI:SS') |
+-----------------------------------------------------+
| 99-12-31 23:59:59                                    |
+-----------------------------------------------------+

SELECT TO_CHAR('21-01-03 08:30:00', 'Y-MONTH-DY HH:MI:SS');
+-----------------------------------------------------+
| TO_CHAR('21-01-03 08:30:00', 'Y-MONTH-DY HH:MI:SS') |
+-----------------------------------------------------+
| 1-January  -Sun 08:30:00                            |
+-----------------------------------------------------+

From MariaDB 12.0, FM removes following padding:

SELECT CONCAT('/', TO_CHAR('2020-01-06 10:11:12', 'DAY'), '/');
+-----------------------------------------------------------+
| CONCAT('/', TO_CHAR('2020-01-06 10:11:12', 'DAY'), '/') |
+-----------------------------------------------------------+
| /Monday   /                                              |
+-----------------------------------------------------------+

SELECT CONCAT('/', TO_CHAR('2020-01-06 10:11:12', 'FMDAY'), '/');
+-------------------------------------------------------------+
| CONCAT('/', TO_CHAR('2020-01-06 10:11:12', 'FMDAY'), '/') |
+-------------------------------------------------------------+
| /Monday/                                                   |
+-------------------------------------------------------------+

Even numbers of FM enable padding, while odd numbers disable it:

SELECT CONCAT('/', TO_CHAR('2020-01-06 10:11:12', 'FMFMDAY'), '/');
+-------------------------------------------------------------+
| CONCAT('/', TO_CHAR('2020-01-06 10:11:12', 'FMFMDAY'), '/') |
+-------------------------------------------------------------+
| /Monday   /                                                |
+-------------------------------------------------------------+

SELECT CONCAT('/', TO_CHAR('2020-01-06 10:11:12', 'FMFMFMDAY'), '/');
```

```
+-------------------------------------------------------------+
| CONCAT('/', TO_CHAR('2020-01-06 10:11:12', 'FMFMFMDAY'), '/') |
+-------------------------------------------------------------+
| /Monday/                                                    |
+-------------------------------------------------------------+

FM only suppresses following padding:

SELECT CONCAT('/', TO_CHAR('2020-01-06 10:11:12', 'DAYFM'), '/');
+-------------------------------------------------------+
| CONCAT('/', TO_CHAR('2020-01-06 10:11:12', 'DAYFM'), '/') |
+-------------------------------------------------------+
| /Monday   /                                           |
+-------------------------------------------------------+
```

< 12.0

```
SELECT TO_CHAR('1980-01-11 04:50:39', 'YYYY-MM-DD');
+-----------------------------------------+
| TO_CHAR('1980-01-11 04:50:39', 'YYYY-MM-DD') |
+-----------------------------------------+
| 1980-01-11                              |
+-----------------------------------------+

SELECT TO_CHAR('1980-01-11 04:50:39', 'HH24-MI-SS');
+-----------------------------------------+
| TO_CHAR('1980-01-11 04:50:39', 'HH24-MI-SS') |
+-----------------------------------------+
| 04-50-39                                |
+-----------------------------------------+

SELECT TO_CHAR('00-01-01 00:00:00', 'YY-MM-DD HH24:MI:SS');
+-----------------------------------------------------+
| TO_CHAR('00-01-01 00:00:00', 'YY-MM-DD HH24:MI:SS') |
+-----------------------------------------------------+
| 00-01-01 00:00:00                                   |
+-----------------------------------------------------+

SELECT TO_CHAR('99-12-31 23:59:59', 'YY-MM-DD HH24:MI:SS');
+-----------------------------------------------------+
| TO_CHAR('99-12-31 23:59:59', 'YY-MM-DD HH24:MI:SS') |
+-----------------------------------------------------+
| 99-12-31 23:59:59                                   |
+-----------------------------------------------------+

SELECT TO_CHAR('9999-12-31 23:59:59', 'YY-MM-DD HH24:MI:SS');
+-----------------------------------------------------+
| TO_CHAR('9999-12-31 23:59:59', 'YY-MM-DD HH24:MI:SS') |
+-----------------------------------------------------+
| 99-12-31 23:59:59                                    |
+-----------------------------------------------------+

SELECT TO_CHAR('21-01-03 08:30:00', 'Y-MONTH-DY HH:MI:SS');
+-----------------------------------------------------+
| TO_CHAR('21-01-03 08:30:00', 'Y-MONTH-DY HH:MI:SS') |
+-----------------------------------------------------+
| 1-January  -Sun 08:30:00                            |
+-----------------------------------------------------+
```

TRIM

Syntax

```
TRIM_ORACLE([{BOTH | LEADING | TRAILING} [remstr] FROM] str), TRIM([remstr FROM] str)
```

Description

Returns the string `str` with all `remstr` prefixes or suffixes removed. If none of the specifiers `BOTH`, `LEADING`, or `TRAILING` is given, `BOTH` is assumed. `remstr` is optional and, if not specified, spaces are removed.

Returns `NULL` if given a `NULL` argument. If the result is empty, returns either an empty string, or, with SQL_MODE=Oracle, `NULL`. `SQL_MODE=Oracle` is not set by default.

The Oracle mode version of the function can be accessed in any mode by using `TRIM_ORACLE` as the function name.

Examples

```
SELECT TRIM('  bar   ')\G
*************************** 1. row ***************************
TRIM('  bar   '): bar

SELECT TRIM(LEADING 'x' FROM 'xxxbarxxx')\G
*************************** 1. row ***************************
TRIM(LEADING 'x' FROM 'xxxbarxxx'): barxxx

SELECT TRIM(BOTH 'x' FROM 'xxxbarxxx')\G
*************************** 1. row ***************************
TRIM(BOTH 'x' FROM 'xxxbarxxx'): bar

SELECT TRIM(TRAILING 'xyz' FROM 'barxxyz')\G
*************************** 1. row ***************************
TRIM(TRAILING 'xyz' FROM 'barxxyz'): barx
```

With SQL_MODE=Oracle not set:

```
SELECT TRIM(''),TRIM_ORACLE('');
+----------+-----------------+
| TRIM('') | TRIM_ORACLE('') |
+----------+-----------------+
|          | NULL            |
+----------+-----------------+
```

With SQL_MODE=Oracle set:

```
SELECT TRIM(''),TRIM_ORACLE('');
+----------+-----------------+
| TRIM('') | TRIM_ORACLE('') |
+----------+-----------------+
| NULL     | NULL            |
+----------+-----------------+
```

See Also

- LTRIM - leading spaces removed
- RTRIM - trailing spaces removed

This page is licensed: GPLv2, originally from fill_help_tables.sql

TRIM_ORACLE

`TRIM_ORACLE` is a synonym for the Oracle mode version of the TRIM function, and is available in all modes.

This page is licensed: CC BY-SA / Gnu FDL

Type Conversion

Implicit type conversion takes place when MariaDB is using operands or different types, in order to make the operands compatible.

It is best practice not to rely upon implicit conversion; rather use CAST to explicitly convert types.

Rules for Conversion on Comparison

- If either argument is NULL, the result of the comparison is NULL unless the NULL-safe <=> equality comparison operator is used.
- If both arguments are integers, they are compared as integers.
- If both arguments are strings, they are compared as strings.
- If one argument is decimal and the other argument is decimal or integer, they are compared as decimals.
- If one argument is decimal and the other argument is a floating point, they are compared as floating point values.
- If one argument is string and the other argument is integer, they are compared as decimals.
- If a hexadecimal argument is not compared to a number, it is treated as a binary string.
- If a constant is compared to a TIMESTAMP or DATETIME, the constant is converted to a timestamp, unless used as an argument to the IN function.
- In other cases, arguments are compared as floating point, or real, numbers.

Note that if a string column is being compared with a numeric value, MariaDB will not use the index on the column, as there are numerous alternatives that may evaluate as equal (see examples below).

Comparison Examples

Converting a string to a number:

```
SELECT 15+'15';
+---------+
| 15+'15' |
+---------+
|      30 |
+---------+
```

Converting a number to a string:

```
SELECT CONCAT(15,'15');
+-----------------+
| CONCAT(15,'15') |
+-----------------+
| 1515            |
+-----------------+
```

Floating point number errors:

```
SELECT '9746718491924563214' = 9746718491924563213;
+-------------------------------------------+
| '9746718491924563214' = 9746718491924563213 |
+-------------------------------------------+
|                                         1 |
+-------------------------------------------+
```

Numeric equivalence with strings:

```
SELECT '5' = 5;
+---------+
| '5' = 5 |
+---------+
|       1 |
+---------+

SELECT '   5' = 5;
+------------+
| '   5' = 5 |
+------------+
|          1 |
+------------+

SELECT '   5  ' = 5;
+--------------+
| '   5  ' = 5 |
+--------------+
|            1 |
+--------------+
1 row in set, 1 warning (0.000 sec)

SHOW WARNINGS;
+-------+------+-------------------------------------------+
| Level | Code | Message                                   |
+-------+------+-------------------------------------------+
| Note  | 1292 | Truncated incorrect DOUBLE value: '   5  ' |
+-------+------+-------------------------------------------+
```

As a result of the above, MariaDB cannot use the index when comparing a string with a numeric value in the example below:

```
CREATE TABLE t (a VARCHAR(10), b VARCHAR(10), INDEX idx_a (a));

INSERT INTO t VALUES
  ('1', '1'), ('2', '2'), ('3', '3'),
  ('4', '4'), ('5', '5'), ('1', '5');

EXPLAIN SELECT * FROM t WHERE a = '3' \G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: t
         type: ref
possible_keys: idx_a
          key: idx_a
      key_len: 13
          ref: const
         rows: 1
        Extra: Using index condition

EXPLAIN SELECT * FROM t WHERE a = 3 \G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: t
         type: ALL
possible_keys: idx_a
          key: NULL
      key_len: NULL
          ref: NULL
         rows: 6
        Extra: Using where
```

Rules for Conversion on Dyadic Arithmetic Operations

Implicit type conversion also takes place on dyadic arithmetic operations (+,-,*,/). MariaDB chooses the minimum data type that is guaranteed to fit the result and converts both arguments to the result data type.

For addition (+), subtraction (-) and multiplication (*), the result data type is chosen as follows:

- If either of the arguments is an approximate number (float, double), the result is double.
- If either of the arguments is a string (char, varchar, text), the result is double.
- If either of the arguments is a decimal number, the result is decimal.
- If either of the arguments is of a temporal type with a non-zero fractional second precision (time(N), datetime(N), timestamp(N)), the result is decimal.
- If either of the arguments is of a temporal type with a zero fractional second precision (time(0), date, datetime(0), timestamp(0)), the result may vary between int, int unsigned, bigint or bigint unsigned, depending on the exact data type combination.
- If both arguments are integer numbers (tinyint, smallint, mediumint, bigint), the result may vary between int, int unsigned, bigint or bigint unsigned, depending of the exact data types and their signs.

For division (/), the result data type is chosen as follows:

- If either of the arguments is an approximate number (float, double), the result is double.
- If either of the arguments is a string (char, varchar, text), the result is double.
- Otherwise, the result is decimal.

Arithmetic Examples

Note, the above rules mean that when an argument of a temporal data type appears in addition or subtraction, it's treated as a number by default.

```
SELECT TIME'10:20:30' + 1;
+--------------------+
| TIME'10:20:30' + 1 |
+--------------------+
|             102031 |
+--------------------+
```

In order to do temporal addition or subtraction instead, use the DATE_ADD() or DATE_SUB() functions, or an INTERVAL expression as the second argument:

```
SELECT TIME'10:20:30' + INTERVAL 1 SECOND;
+-----------------------------------+
| TIME'10:20:30' + INTERVAL 1 SECOND |
+-----------------------------------+
| 10:20:31                          |
+-----------------------------------+
```

```
SELECT "2.2" + 3;
+-----------+
| "2.2" + 3 |
+-----------+
|       5.2 |
+-----------+

SELECT 2.2 + 3;
+---------+
| 2.2 + 3 |
+---------+
| 5.2     |
+---------+

SELECT 2.2 / 3;
+---------+
| 2.2 / 3 |
+---------+
| 0.73333 |
+---------+

SELECT "2.2" / 3;
+--------------------+
| "2.2" / 3          |
+--------------------+
| 0.7333333333333334 |
+--------------------+
```

UCASE

Syntax

```
UCASE(str)
```

Description

`UCASE()` is a synonym for UPPER().

This page is licensed: GPLv2, originally from fill_help_tables.sql

UNHEX

Syntax

```
UNHEX(str)
```

Description

Performs the inverse operation of HEX(str). That is, it interprets each pair of hexadecimal digits in the argument as a number and converts it to the character represented by the number. The resulting characters are returned as a binary string.

If `str` is `NULL`, `UNHEX()` returns `NULL`.

Examples

```
SELECT HEX('MariaDB');
+----------------+
| HEX('MariaDB') |
+----------------+
| 4D617269614442 |
+----------------+

SELECT UNHEX('4D617269614442');
+-------------------------+
| UNHEX('4D617269614442') |
+-------------------------+
| MariaDB                 |
+-------------------------+

SELECT 0x4D617269614442;
+------------------+
| 0x4D617269614442 |
+------------------+
| MariaDB          |
+------------------+

SELECT UNHEX(HEX('string'));
+----------------------+
| UNHEX(HEX('string')) |
+----------------------+
| string               |
+----------------------+

SELECT HEX(UNHEX('1267'));
+--------------------+
| HEX(UNHEX('1267')) |
+--------------------+
| 1267               |
+--------------------+
```

- Hexadecimal literals
- HEX()
- CONV()

This page is licensed: GPLv2, originally from fill_help_tables.sql

UPDATEXML

Syntax

```
UpdateXML(xml_target, xpath_expr, new_xml)
```

Description

This function replaces a single portion of a given fragment of XML markup `xml_target` with a new XML fragment `new_xml`, and then returns the changed XML. The portion of `xml_target` that is replaced matches an XPath expression `xpath_expr` supplied by the user. If no expression matching `xpath_expr` is found, or if multiple matches are found, the function returns the original `xml_target` XML fragment. All three arguments should be strings.

Examples

```
SELECT
    UpdateXML('<a><b>ccc</b><d></d></a>', '/a', '<e>fff</e>') AS val1,
    UpdateXML('<a><b>ccc</b><d></d></a>', '/b', '<e>fff</e>') AS val2,
    UpdateXML('<a><b>ccc</b><d></d></a>', '//b', '<e>fff</e>') AS val3,
    UpdateXML('<a><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val4,
    UpdateXML('<a><d></d><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val5
    \G
*************************** 1. row ***************************
val1: <e>fff</e>
val2: <a><b>ccc</b><d></d></a>
val3: <a><e>fff</e><d></d></a>
val4: <a><b>ccc</b><e>fff</e></a>
val5: <a><d></d><b>ccc</b><d></d></a>
1 row in set (0.00 sec)
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

UPPER

Syntax

```
UPPER(str)
UCASE(str)
```

Description

Returns the string `str` with all characters changed to uppercase according to the current character set mapping. The default is latin1 (cp1252 West European). The result may depend on the collation and character set used. `UCASE` is a synonym.

```
SELECT UPPER(surname), givenname FROM users ORDER BY surname;
+----------------+------------+
| UPPER(surname) | givenname  |
+----------------+------------+
| ABEL           | Jacinto    |
| CASTRO         | Robert     |
| COSTA          | Phestos    |
| MOSCHELLA      | Hippolytos |
+----------------+------------+
```

`UPPER()` is ineffective when applied to binary strings (BINARY, VARBINARY, BLOB). The description of LOWER() shows how to perform lettercase conversion of binary strings.

This page is licensed: GPLv2, originally from fill_help_tables.sql

WEIGHT_STRING

Syntax

```
WEIGHT_STRING(str [AS {CHAR|BINARY}(N)] [LEVEL levels] [flags])
  levels: N [ASC|DESC|REVERSE] [, N [ASC|DESC|REVERSE]] ...
```

Description

Returns a binary string representing the string's sorting and comparison value. A string with a lower result means that for sorting purposes the string appears before a string with a higher result.

`WEIGHT_STRING()` is particularly useful when adding new collations, for testing purposes.

If `str` is a non-binary string (CHAR, VARCHAR or TEXT), WEIGHT_STRING returns the string's collation weight. If `str` is a binary string (BINARY, VARBINARY or BLOB), the return value is simply the input value, since the weight for each byte in a binary string is the byte value.

`WEIGHT_STRING()` returns `NULL` if given a `NULL` input.

The optional AS clause permits casting the input string to a binary or non-binary string, as well as to a particular length.

`AS BINARY(N)` measures the length in bytes rather than characters, and right pads with 0x00 bytes to the desired length.

`AS CHAR(N)` measures the length in characters, and right pads with spaces to the desired length.

N has a minimum value of 1, and if it is less than the length of the input string, the string is truncated without warning.

The optional `LEVEL` clause specifies that the return value should contain weights for specific collation levels. The `levels` specifier can either be a single integer, a comma-separated list of integers, or a range of integers separated by a dash (whitespace is ignored). Integers can range from 1 to a maximum of 6, dependent on the collation, and need to be listed in ascending order.

If the `LEVEL` clause is no provided, a default of 1 to the maximum for the collation is assumed.

If the `q` is specified without using a range, an optional modifier is permitted.

`ASC`, the default, returns the weights without any modification.

`DESC` returns bitwise-inverted weights.

`REVERSE` returns the weights in reverse order.

Examples

The examples below use the HEX() function to represent non-printable results in hexadecimal format.

```
SELECT HEX(WEIGHT_STRING('x'));
+-------------------------+
| HEX(WEIGHT_STRING('x')) |
+-------------------------+
| 0058                    |
+-------------------------+

SELECT HEX(WEIGHT_STRING('x' AS BINARY(4)));
+--------------------------------------+
| HEX(WEIGHT_STRING('x' AS BINARY(4))) |
+--------------------------------------+
| 78000000                             |
+--------------------------------------+

SELECT HEX(WEIGHT_STRING('x' AS CHAR(4)));
+-----------------------------------+
| HEX(WEIGHT_STRING('x' AS CHAR(4))) |
+-----------------------------------+
| 0058002000200020                  |
+-----------------------------------+

SELECT HEX(WEIGHT_STRING(0xaa22ee LEVEL 1));
+--------------------------------------+
| HEX(WEIGHT_STRING(0xaa22ee LEVEL 1)) |
+--------------------------------------+
| AA22EE                               |
+--------------------------------------+

SELECT HEX(WEIGHT_STRING(0xaa22ee LEVEL 1 DESC));
+-----------------------------------------+
| HEX(WEIGHT_STRING(0xaa22ee LEVEL 1 DESC)) |
+-----------------------------------------+
| 55DD11                                  |
+-----------------------------------------+

SELECT HEX(WEIGHT_STRING(0xaa22ee LEVEL 1 REVERSE));
+-------------------------------------------+
| HEX(WEIGHT_STRING(0xaa22ee LEVEL 1 REVERSE)) |
+-------------------------------------------+
| EE22AA                                    |
+-------------------------------------------+
```

Regular Expressions Functions

See Regular Expressions Overview.

Get an overview of regex usage. This page introduces the pattern matching capabilities and common metacharacters used in MariaDB regular expressions.

See PCRE - Perl Compatible Regular Expressions.

Understand MariaDB's regex support. This concept page explains the PCRE library integration, detailing supported syntax, character classes, and special characters.

See REGEXP.

Complete REGEXP operator reference: expr REGEXP/RLIKE pat syntax, 1/0/NULL return values, NOT REGEXP aliases, BINARY case-sensitivity, default_regex_flags.

See NOT REGEXP.

Negated regular expression matching. This operator tests whether a string does NOT match a specified regular expression pattern.

See REGEXP_INSTR.

Return the index of a regex match. This function finds the starting position of the first substring that matches the given pattern.

See REGEXP_REPLACE.

Replace regex matches in a string. This function substitutes occurrences of a pattern with a specified replacement string.

See REGEXP_SUBSTR.

Return the substring matching a regex. This function extracts the actual part of the string that matches the given pattern.

See RLIKE.

Synonym for REGEXP. This operator performs a regular expression match against a string argument.

This page is licensed: CC BY-SA / Gnu FDL

Regular Expressions Overview

Regular Expressions allow MariaDB to perform complex pattern matching on a string. In many cases, the simple pattern matching provided by LIKE is sufficient. `LIKE` performs two kinds of matches:

- `_` - the underscore, matching a single character
- `%` - the percentage sign, matching any number of characters.

In other cases you may need more control over the returned matches, and will need to use regular expressions.

Regular expression matches are performed with the REGEXP function. `RLIKE` is a synonym for `REGEXP`.

Comparisons are performed on the byte value, so characters that are treated as equivalent by a collation, but do not have the same byte-value, such as accented characters, could evaluate as unequal.

Without any special characters, a regular expression match is true if the characters match. The match is case-insensitive, except in the case of BINARY strings.

```
SELECT 'Maria' REGEXP 'Maria';
+------------------------+
| 'Maria' REGEXP 'Maria' |
+------------------------+
|                      1 |
+------------------------+

SELECT 'Maria' REGEXP 'maria';
+------------------------+
| 'Maria' REGEXP 'maria' |
+------------------------+
|                      1 |
+------------------------+

SELECT BINARY 'Maria' REGEXP 'maria';
+-------------------------------+
| BINARY 'Maria' REGEXP 'maria' |
+-------------------------------+
|                             0 |
+-------------------------------+
```

Note that the word being matched must match the whole pattern:

```
SELECT 'Maria' REGEXP 'Mari';
+----------------------+
| 'Maria' REGEXP 'Mari' |
+----------------------+
|                    1 |
+----------------------+

SELECT 'Mari' REGEXP 'Maria';
+----------------------+
| 'Mari' REGEXP 'Maria' |
+----------------------+
|                    0 |
+----------------------+
```

The first returns true because the pattern “Mari” exists in the expression “Maria”. When the order is reversed, the result is false, as the pattern “Maria” does not exist in the expression “Mari”

A match can be performed against more than one word with the `|` character. For example:

```
SELECT 'Maria' REGEXP 'Monty|Maria';
+-----------------------------+
| 'Maria' REGEXP 'Monty|Maria' |
+-----------------------------+
|                           1 |
+-----------------------------+
```

Special Characters

The above examples introduce the syntax, but are not very useful on their own. It’s the special characters that give regular expressions their power.

^

`^` matches the beginning of a string (inside square brackets it can also mean `NOT` - see below):

```
SELECT 'Maria' REGEXP '^Ma';
+---------------------+
| 'Maria' REGEXP '^Ma' |
+---------------------+
|                   1 |
+---------------------+
```

$

`$` matches the end of a string:

```
SELECT 'Maria' REGEXP 'ia$';
+---------------------+
| 'Maria' REGEXP 'ia$' |
+---------------------+
|                   1 |
+---------------------+
```

.

`.` matches any single character:

```
SELECT 'Maria' REGEXP 'Ma.ia';
+-----------------------+
| 'Maria' REGEXP 'Ma.ia' |
+-----------------------+
|                     1 |
+-----------------------+

SELECT 'Maria' REGEXP 'Ma..ia';
+------------------------+
| 'Maria' REGEXP 'Ma..ia' |
+------------------------+
|                      0 |
+------------------------+
```

*****

`x*` matches zero or more of a character `x`. In the examples below, it's the `r` character.

```
SELECT 'Maria' REGEXP 'Mar*ia';
+------------------------+
| 'Maria' REGEXP 'Mar*ia' |
+------------------------+
|                      1 |
+------------------------+

SELECT 'Maia' REGEXP 'Mar*ia';
+-----------------------+
| 'Maia' REGEXP 'Mar*ia' |
+-----------------------+
|                     1 |
+-----------------------+

SELECT 'Marrria' REGEXP 'Mar*ia';
+--------------------------+
| 'Marrria' REGEXP 'Mar*ia' |
+--------------------------+
|                        1 |
+--------------------------+
```

+

`x+` matches one or more of a character `x`. In the examples below, it's the `r` character.

```
SELECT 'Maria' REGEXP 'Mar+ia';
+------------------------+
| 'Maria' REGEXP 'Mar+ia' |
+------------------------+
|                      1 |
+------------------------+

SELECT 'Maia' REGEXP 'Mar+ia';
+-----------------------+
| 'Maia' REGEXP 'Mar+ia' |
+-----------------------+
|                     0 |
+-----------------------+

SELECT 'Marrria' REGEXP 'Mar+ia';
+--------------------------+
| 'Marrria' REGEXP 'Mar+ia' |
+--------------------------+
|                        1 |
+--------------------------+
```

?

`x?` matches zero or one of a character `x`. In the examples below, it's the `r` character.

```
SELECT 'Maria' REGEXP 'Mar?ia';
+-------------------------+
| 'Maria' REGEXP 'Mar?ia' |
+-------------------------+
|                       1 |
+-------------------------+

SELECT 'Maia' REGEXP 'Mar?ia';
+------------------------+
| 'Maia' REGEXP 'Mar?ia' |
+------------------------+
|                      1 |
+------------------------+

SELECT 'Marrria' REGEXP 'Mar?ia';
+--------------------------+
| 'Marrria' REGEXP 'Mar?ia' |
+--------------------------+
|                        0 |
+--------------------------+
```

()

`(xyz)` - combine a sequence, for example `(xyz)+` or `(xyz)*`

```
SELECT 'Maria' REGEXP '(ari)+';
+-------------------------+
| 'Maria' REGEXP '(ari)+' |
+-------------------------+
|                       1 |
+-------------------------+
```

`x{n}` and `x{m,n}`
This notation is used to match many instances of the `x`. In the case of `x{n}` the match must be exactly that many times. In the case of `x{m,n}`, the match can occur from `m` to `n` times. For example, to match zero or one instance of the string `ari` (which is identical to `(ari)?`), the following can be used:

```
SELECT 'Maria' REGEXP '(ari){0,1}';
+-----------------------------+
| 'Maria' REGEXP '(ari){0,1}' |
+-----------------------------+
|                           1 |
+-----------------------------+
```

[]

`[xy]` groups characters for matching purposes. For example, to match either the `p` or the `r` character:

```
SELECT 'Maria' REGEXP 'Ma[pr]ia';
+---------------------------+
| 'Maria' REGEXP 'Ma[pr]ia' |
+---------------------------+
|                         1 |
+---------------------------+
```

The square brackets also permit a range match, for example, to match any character from a-z, `[a-z]` is used. Numeric ranges are also permitted.

```
SELECT 'Maria' REGEXP 'Ma[a-z]ia';
+---------------------------+
| 'Maria' REGEXP 'Ma[a-z]ia' |
+---------------------------+
|                         1 |
+---------------------------+
```

The following does not match, as `r` falls outside of the range `a-p`.

```
SELECT 'Maria' REGEXP 'Ma[a-p]ia';
+---------------------------+
| 'Maria' REGEXP 'Ma[a-p]ia' |
+---------------------------+
|                         0 |
+---------------------------+
```

^

The `^` character means does `NOT` match, for example:

```
SELECT 'Maria' REGEXP 'Ma[^p]ia';
+---------------------------+
| 'Maria' REGEXP 'Ma[^p]ia' |
+---------------------------+
|                         1 |
+---------------------------+

SELECT 'Maria' REGEXP 'Ma[^r]ia';
+---------------------------+
| 'Maria' REGEXP 'Ma[^r]ia' |
+---------------------------+
|                         0 |
+---------------------------+
```

The `[` and `]` characters on their own can be literally matched inside a `[]` block, without escaping, as long as they immediately match the opening bracket:

```
SELECT '[Maria' REGEXP '[[]';
+-----------------------+
| '[Maria' REGEXP '[[]' |
+-----------------------+
|                     1 |
+-----------------------+

SELECT '[Maria' REGEXP '[]]';
+-----------------------+
| '[Maria' REGEXP '[]]' |
+-----------------------+
|                     0 |
+-----------------------+

SELECT ']Maria' REGEXP '[]]';
+-----------------------+
| ']Maria' REGEXP '[]]' |
+-----------------------+
|                     1 |
+-----------------------+

SELECT ']Maria' REGEXP '[]a]';
+-----------------------+
| ']Maria' REGEXP '[]a]' |
+-----------------------+
|                      1 |
+-----------------------+
```

Incorrect order, so no match:

```
SELECT ']Maria' REGEXP '[a]]';
+-----------------------+
| ']Maria' REGEXP '[a]]' |
+-----------------------+
|                     0 |
+-----------------------+
```

The `-` character can also be matched in the same way:

```
SELECT '-Maria' REGEXP '[1-10]';
+-------------------------+
| '-Maria' REGEXP '[1-10]' |
+-------------------------+
|                       0 |
+-------------------------+

SELECT '-Maria' REGEXP '[-1-10]';
+--------------------------+
| '-Maria' REGEXP '[-1-10]' |
+--------------------------+
|                        1 |
+--------------------------+
```

Word boundaries

The :<: and :>: patterns match the beginning and the end of a word respectively. For example:

```
SELECT 'How do I upgrade MariaDB?' REGEXP '[[:<:]]MariaDB[[:>:]]';
+-----------------------------------------------------------+
| 'How do I upgrade MariaDB?' REGEXP '[[:<:]]MariaDB[[:>:]]' |
+-----------------------------------------------------------+
|                                                         1 |
+-----------------------------------------------------------+

SELECT 'How do I upgrade MariaDB?' REGEXP '[[:<:]]Maria[[:>:]]';
+-----------------------------------------------------------+
| 'How do I upgrade MariaDB?' REGEXP '[[:<:]]Maria[[:>:]]' |
+-----------------------------------------------------------+
|                                                       0 |
+-----------------------------------------------------------+
```

Character Classes

There are a number of shortcuts to match particular preset character classes. These are matched with the `[:character_class:]` pattern (inside a `[]` set). The following character classes exist:

Character Class	Description
alnum	Alphanumeric
alpha	Alphabetic
blank	Whitespace
cntrl	Control characters
digit	Digits
graph	Graphic characters
lower	Lowercase alphabetic
print	Graphic or space characters
punct	Punctuation

Character Class	Description
space	Space, tab, newline, and carriage return
upper	Uppercase alphabetic
xdigit	Hexadecimal digit

For example:

```
SELECT 'Maria' REGEXP 'Mar[[:alnum:]]*';
+--------------------------------+
| 'Maria' REGEXP 'Mar[:alnum:]*' |
+--------------------------------+
|                              1 |
+--------------------------------+
```

Remember that matches are by default case-insensitive, unless a binary string is used, so the following example, specifically looking for an uppercase, counter-intuitively matches a lowercase character:

```
SELECT 'Mari' REGEXP 'Mar[[:upper:]]+';
+--------------------------------+
| 'Mari' REGEXP 'Mar[[:upper:]]+' |
+--------------------------------+
|                               1 |
+--------------------------------+

SELECT BINARY 'Mari' REGEXP 'Mar[[:upper:]]+';
+---------------------------------------+
| BINARY 'Mari' REGEXP 'Mar[[:upper:]]+' |
+---------------------------------------+
|                                     0 |
+---------------------------------------+
```

Character Names

There are also number of shortcuts to match particular preset character names. These are matched with the `[.character.]` pattern (inside a `[]` set). The following character classes exist:

Name	Character
NUL	0
SOH	001
STX	002
ETX	003
EOT	004
ENQ	005
ACK	006
BEL	007
alert	007
BS	010
backspace	'\b'
HT	011
tab	'\t'
LF	012
newline	'\n'

Name	Character
VT	013
vertical-tab	‘\v’
FF	014
form-feed	‘\f’
CR	015
carriage-return	‘\r’
SO	016
SI	017
DLE	020
DC1	021
DC2	022
DC3	023
DC4	024
NAK	025
SYN	026
ETB	027
CAN	030
EM	031
SUB	032
ESC	033
IS4	034
FS	034
IS3	035
GS	035
IS2	036
RS	036
IS1	037
US	037
space	’ ’
exclamation-mark	‘!’
quotation-mark	‘“’
number-sign	‘#’
dollar-sign	‘$’
percent-sign	‘%’
ampersand	‘&’
apostrophe	‘’’
left-parenthesis	‘(’
right-parenthesis	‘)’
asterisk	‘*’

Name	Character
plus-sign	‘+’
comma	‘,’
hyphen	‘-’
hyphen-minus	‘-’
period	‘.’
full-stop	‘.’
slash	‘/’
solidus	‘/’
zero	‘0’
one	‘1’
two	‘2’
three	‘3’
four	‘4’
five	‘5’
six	‘6’
seven	‘7’
eight	‘8’
nine	‘9’
colon	‘:’
semicolon	‘;’
less-than-sign	‘<’
equals-sign	‘=’
greater-than-sign	‘>’
question-mark	‘?’
commercial-at	‘@’
left-square-bracket	‘[’
backslash	”
reverse-solidus	”
right-square-bracket	‘]’
circumflex	‘^’
circumflex-accent	‘^’
underscore	‘_’
low-line	‘_’
grave-accent	‘`’
left-brace	‘{’
left-curly-bracket	‘{’
vertical-line	’
right-brace	‘}’
right-curly-bracket	‘}’

Name	Character
tilde	”
DEL	177

For example:

```
SELECT '|' REGEXP '[[.vertical-line.]]';
+---------------------------------+
| '|' REGEXP '[[.vertical-line.]]' |
+---------------------------------+
|                               1 |
+---------------------------------+
```

Combining

The true power of regular expressions is unleashed when the above is combined, to form more complex examples. Regular expression’s reputation for complexity stems from the seeming complexity of multiple combined regular expressions, when in reality, it’s simply a matter of understanding the characters and how they apply:

The first example fails to match, as while the `Ma` matches, either `i` or `r` only matches once before the `ia` characters at the end.

```
SELECT 'Maria' REGEXP 'Ma[ir]{2}ia';
+-----------------------------+
| 'Maria' REGEXP 'Ma[ir]{2}ia' |
+-----------------------------+
|                           0 |
+-----------------------------+
```

This example matches, as either `i` or `r` match exactly twice after the `Ma`, in this case one `r` and one `i`.

```
SELECT 'Maria' REGEXP 'Ma[ir]{2}';
+---------------------------+
| 'Maria' REGEXP 'Ma[ir]{2}' |
+---------------------------+
|                         1 |
+---------------------------+
```

Escaping

With the large number of special characters, care needs to be taken to properly escape characters. Two backslash characters, `` (one for the MariaDB parser, one for the regex library), are required to properly escape a character. For example:

To match the literal `(Ma`:

```
SELECT '(Maria)' REGEXP '(Ma';
ERROR 1139 (42000): Got error 'parentheses not balanced' from regexp

SELECT '(Maria)' REGEXP '\(Ma';
ERROR 1139 (42000): Got error 'parentheses not balanced' from regexp

SELECT '(Maria)' REGEXP '\\(Ma';
+-------------------------+
| '(Maria)' REGEXP '\\(Ma' |
+-------------------------+
|                       1 |
+-------------------------+
```

To match `r+`: The first two examples are incorrect, as they match `r` one or more times, not `r+`:

```
SELECT 'Mar+ia' REGEXP 'r+';
+----------------------+
| 'Mar+ia' REGEXP 'r+' |
+----------------------+
|                    1 |
+----------------------+

SELECT 'Maria' REGEXP 'r+';
+--------------------+
| 'Maria' REGEXP 'r+' |
+--------------------+
|                  1 |
+--------------------+

SELECT 'Maria' REGEXP 'r\\+';
+----------------------+
| 'Maria' REGEXP 'r\\+' |
+----------------------+
|                    0 |
+----------------------+

SELECT 'Maria' REGEXP 'r+';
+--------------------+
| 'Maria' REGEXP 'r+' |
+--------------------+
|                  1 |
+--------------------+
```

PCRE - Perl Compatible Regular Expressions

PCRE Versions

PCRE Version	Introduced	Maturity
PCRE2 10.34	MariaDB 10.5.1	Stable
PCRE 8.43	MariaDB 10.1.39	Stable
PCRE 8.42	MariaDB 10.2.15, MariaDB 10.1.33, MariaDB 10.0.35	Stable
PCRE 8.41	MariaDB 10.2.8, MariaDB 10.1.26, MariaDB 10.0.32	Stable
PCRE 8.40	MariaDB 10.2.5, MariaDB 10.1.22, MariaDB 10.0.30	Stable
PCRE 8.39	MariaDB 10.1.15, MariaDB 10.0.26	Stable
PCRE 8.38	MariaDB 10.1.10, MariaDB 10.0.23	Stable
PCRE 8.37	MariaDB 10.1.5, MariaDB 10.0.18	Stable
PCRE 8.36	MariaDB 10.1.2, MariaDB 10.0.15	Stable
PCRE 8.35	MariaDB 10.1.0, MariaDB 10.0.12	Stable
PCRE 8.34	MariaDB 10.0.8	Stable

PCRE Enhancements

MariaDB uses the PCRE library, which significantly improves the power of the REGEXP/RLIKE operator.

The switch to PCRE added a number of features, including recursive patterns, named capture, look-ahead and look-behind assertions, non-capturing groups, non-greedy quantifiers, Unicode character properties, extended syntax for characters and character classes, multi-line matching, and many other.

These functions work with regular expressions: REGEXP_REPLACE(), REGEXP_INSTR(), and REGEXP_SUBSTR().

Also, `REGEXP/RLIKE`, and the new functions, work correctly with all multi-byte character sets supported by MariaDB, including East-Asian character sets (big5, gb2313, gbk, eucjp, eucjpms, cp932, ujis, euckr), and Unicode character sets (utf8, utf8mb4, ucs2, utf16, utf16le, utf32).

New Regular Expression Functions

- REGEXP_REPLACE(subject, pattern, replace) - Replaces all occurrences of a pattern.
- REGEXP_INSTR(subject, pattern) - Position of the first appearance of a regex.
- REGEXP_SUBSTR(subject,pattern) - Returns the matching part of a string.

See the individual articles for more details and examples.

PCRE Syntax

In most cases PCRE is backward compatible with the old POSIX 1003.2 compliant regexp library (see Regular Expressions Overview), so you won't need to change your applications that use SQL queries with the REGEXP/RLIKE predicate.

This section briefly describes the most important extended PCRE features. For more details, please refer to the documentation on the PCRE site, or to the documentation which is bundled in the /pcre/doc/html/ directory of a MariaDB sources distribution. The pages pcresyntax.html and pcrepattern.html should be a good start. Regular-Expressions.Info is another good resource to learn about PCRE and regular expressions generally.

Special Characters

PCRE supports the following escape sequences to match special characters:

Sequence	Description
\a	0x07 (BEL)
\cx	"control-x", where x is any ASCII character
\e	0x1B (escape)
\f	0x0C (form feed)
	0x0A (newline)
	0x0D (carriage return)
	0x09 (TAB)
\ddd	character with octal code ddd
\xhh	character with hex code hh
\x{hhh..}	character with hex code hhh..

Note, the backslash characters (here, and in all examples in the sections below) must be escaped with another backslash, unless you're using the SQL_MODE `NO_BACKSLASH_ESCAPES`.

This example tests if a character has hex code 0x61:

```
SELECT 'a' RLIKE '\\x{61}';
-> 1
```

Character Classes

PCRE supports the standard POSIX character classes such as `alnum`, `alpha`, `blank`, `cntrl`, `digit`, `graph`, `lower`, `print`, `punct`, `space`, `upper`, `xdigit`, with the following additional classes:

Class	Description
ascii	any ASCII character (0x00..0x7F)
word	any “word” character (a letter, a digit, or an underscore)

This example checks if the string consists of ASCII characters only:

```
SELECT 'abc' RLIKE '^[[:ascii:]]+$';
-> 1
```

Generic Character Types

Generic character types complement the POSIX character classes and serve to simplify writing patterns:

Class	Description
\d	a decimal digit (same as [:digit:])
\D	a character that is not a decimal digit
\h	a horizontal white space character
\H	a character that is not a horizontal white space character
	a character that is not a new line
	a newline sequence
\s	a white space character
\S	a character that is not a white space character
\v	a vertical white space character
\V	a character that is not a vertical white space character
\w	a “word” character (same as [:word:])
\W	a “non-word” character

This example checks if the string consists of “word” characters only:

```
SELECT 'abc' RLIKE '^\\w+$';
-> 1
```

Unicode Character Properties

`\p{xx}` is a character with the `xx` property, and `\P{xx}` is a character without the `xx` property.

The property names represented by `xx` above are limited to the Unicode script names, the general category properties, and “Any”, which matches any character (including newline). Those that are not part of an identified script are lumped together as “Common”.

General Category Properties For \p and \P

Property	Description
C	Other
Cc	Control
Cf	Format
Cn	Unassigned
Co	Private use
Cs	Surrogate

Property	Description
L	Letter
Ll	Lower case letter
Lm	Modifier letter
Lo	Other letter
Lt	Title case letter
Lu	Upper case letter
L&	Ll, Lu, or Lt
M	Mark
Mc	Spacing mark
Me	Enclosing mark
Mn	Non-spacing mark
N	Number
Nd	Decimal number
Nl	Letter number
No	Other number
P	Punctuation
Pc	Connector punctuation
Pd	Dash punctuation
Pe	Close punctuation
Pf	Final punctuation
Pi	Initial punctuation
Po	Other punctuation
Ps	Open punctuation
S	Symbol
Sc	Currency symbol
Sk	Modifier symbol
Sm	Mathematical symbol
So	Other symbol
Z	Separator
Zl	Line separator
Zp	Paragraph separator
Zs	Space separator

This example checks if the string consists only of characters with property N (number):

```
SELECT '1¼①' RLIKE '^\\p{N}+$';
-> 1
```

Special Category Properties For \p and \P

Property	Description
Xan	Alphanumeric: union of properties L and N

Property	Description
Xps	POSIX space: property Z or tab, NL, VT, FF, CR
Xsp	Perl space: property Z or tab, NL, FF, CR
Xuc	A character than can be represented by a Universal Character Name
Xwd	Perl word: property Xan or underscore

The property `Xuc` matches any character that can be represented by a Universal Character Name (in C++ and other programming languages). These include `$`, `@`, ```, and all characters with Unicode code points greater than `U+00A0`, excluding the surrogates `U+D800`..`U+DFFF`.

Script Names For \p and \P

Arabic, Armenian, Avestan, Balinese, Bamum, Batak, Bengali, Bopomofo, Brahmi, Braille, Buginese, Buhid, Canadian_Aboriginal, Carian, Chakma, Cham, Cherokee, Common, Coptic, Cuneiform, Cypriot, Cyrillic, Deseret, Devanagari, Egyptian_Hieroglyphs, Ethiopic, Georgian, Glagolitic, Gothic, Greek, Gujarati, Gurmukhi, Han, Hangul, Hanunoo, Hebrew, Hiragana, Imperial_Aramaic, Inherited, Inscriptional_Pahlavi, Inscriptional_Parthian, Javanese, Kaithi, Kannada, Katakana, Kayah_Li, Kharoshthi, Khmer, Lao, Latin, Lepcha, Limbu, Linear_B, Lisu, Lycian, Lydian, Malayalam, Mandaic, Meetei_Mayek, Meroitic_Cursive, Meroitic_Hieroglyphs, Miao, Mongolian, Myanmar, New_Tai_Lue, Nko, Ogham, Old_Italic, Old_Persian, Old_South_Arabian, Old_Turkic, Ol_Chiki, Oriya, Osmanya, Phags_Pa, Phoenician, Rejang, Runic, Samaritan, Saurashtra, Sharada, Shavian, Sinhala, Sora_Sompeng, Sundanese, Syloti_Nagri, Syriac, Tagalog, Tagbanwa, Tai_Le, Tai_Tham, Tai_Viet, Takri, Tamil, Telugu, Thaana, Thai, Tibetan, Tifinagh, Ugaritic, Vai, Yi.

This example checks if the string consists only of Greek characters:

```
SELECT 'ΣΦΩ' RLIKE '^\\p{Greek}+$';
-> 1
```

Extended Unicode Grapheme Sequence

The `\X` escape sequence matches a character sequence that makes an “extended grapheme cluster”, i.e. a composite character that consists of multiple Unicode code points.

One of the examples of a composite character can be a letter followed by non-spacing accent marks. This example demonstrates that `U+0045 LATIN CAPITAL LETTER E` followed by `U+0302 COMBINING CIRCUMFLEX ACCENT` followed by `U+0323 COMBINING DOT BELOW` together form an extended grapheme cluster:

```
SELECT _ucs2 0x004503020323 RLIKE '^\\X$';
-> 1
```

See the PCRE documentation for the other types of extended grapheme clusters.

Simple Assertions

An assertion specifies a certain condition that must match at a particular point, but without consuming characters from the subject string. In addition to the standard POSIX simple assertions `^` (that matches at the beginning of a line) and `$` (that matches at the end of a line), PCRE supports a number of other assertions:

Assertion	Description
\b	matches at a word boundary
\B	matches when not at a word boundary
\A	matches at the start of the subject
\Z	matches at the end of the subject, also matches before a newline at the end of the subject

Assertion	Description
\z	matches only at the end of the subject
\G	matches at the first matching position in the subject

This example cuts a word that consists only of 3 characters from a string:

```
SELECT REGEXP_SUBSTR('---abcd---xyz---', '\\b\\w{3}\\b');
-> xyz
```

Notice that the two `\b` assertions checked the word boundaries but did not get into the matching pattern.

The `\b` assertions work well in the beginning and the end of the subject string:

```
SELECT REGEXP_SUBSTR('xyz', '\\b\\w{3}\\b');
-> xyz
```

By default, the `^` and `$` assertions have the same meaning with `\A`, `\Z`, and `\z`. However, the meanings of `^` and `$` can change in multiline mode (see below). By contrast, the meanings of `\A`, `\Z`, and `\z` are always the same; they are independent of the multiline mode.

Option Setting

A number of options that control the default match behavior can be changed within the pattern by a sequence of option letters enclosed between `(?` and `)`.

Option	Description
(?i)	case insensitive match
(?m)	multiline mode
(?s)	dotall mode (dot matches newline characters)
(?x)	extended (ignore white space)
(?U)	ungreedy (lazy) match
(?J)	allow named subpatterns with duplicate names
(?X)	extra PCRE functionality (e.g. force error on unknown escaped character)
(?-…)	unset option(s)

For example, `(?im)` sets case insensitive multiline matching.

A hyphen followed by the option letters unset the options. For example, `(?-im)` means case sensitive single line match.

A combined setting and unsetting is also possible, e.g. `(?im-sx)`.

If an option is set outside of subpattern parentheses, the option applies to the remainder of the pattern that follows the option. If an option is set inside a subpattern, it applies to the part of this subpattern that follows the option.

In this example the pattern `(?i)m((?-i)aria)db` matches the words `MariaDB`, `Mariadb`, `mariadb`, but not `MARIADB`:

```
SELECT 'MariaDB' RLIKE '(?i)m((?-i)aria)db';
-> 1

SELECT 'mariaDB' RLIKE '(?i)m((?-i)aria)db';
-> 1

SELECT 'Mariadb' RLIKE '(?i)m((?-i)aria)db';
-> 1

SELECT 'MARIADB' RLIKE '(?i)m((?-i)aria)db';
-> 0
```

This example demonstrates that the `(?x)` option makes the regexp engine ignore all white spaces in the pattern (other than in a class).

```
SELECT 'ab' RLIKE '(?x)a b';
-> 1
```

Note, putting spaces into a pattern in combination with the (?x) option can be useful to split different logical parts of a complex pattern, to make it more readable.

Multiline Matching

Multiline matching changes the meaning of `^` and `$` from “the beginning of the subject string” and “the end of the subject string” to “the beginning of any line in the subject string” and “the end of any line in the subject string” respectively.

This example checks if the subject string contains two consequent lines that fully consist of digits:

```
SELECT 'abc\n123\n456\nxyz\n' RLIKE '(?m)^\\d+\\R\\d+$';
-> 1
```

Notice the `(?m)` option in the beginning of the pattern, which switches to the multiline matching mode.

Newline Conventions

PCRE supports five line break conventions:

- `CR (\r)` - a single carriage return character
- `LF (\n)` - a single linefeed character
- `CRLF (\r\n)` - a carriage return followed by a linefeed
- any of the previous three
- any Unicode newline sequence

By default, the newline convention is set to any Unicode newline sequence, which includes:

Sequence	Description
LF	(U+000A, carriage return)
CR	(U+000D, carriage return)
CRLF	(a carriage return followed by a linefeed)
VT	(U+000B, vertical tab)
FF	(U+000C, form feed)
NEL	(U+0085, next line)
LS	(U+2028, line separator)
PS	(U+2029, paragraph separator)

The newline convention can be set by starting a pattern with one of the following sequences:

Sequence	Description
(*CR)	carriage return
(*LF)	linefeed
(*CRLF)	carriage return followed by linefeed
(*ANYCRLF)	any of the previous three
(*ANY)	all Unicode newline sequences

The newline conversion affects the `^` and `$` assertions, the interpretation of the dot metacharacter, and the behavior of .

Note, the new line convention does not affect the meaning of .

This example demonstrates that the dot metacharacter matches , because it is not a newline sequence anymore:

```
SELECT 'a\nb' RLIKE '(*CR)a.b';
-> 1
```

Newline Sequences

By default, the escape sequence matches any Unicode newline sequences.

The meaning of can be set by starting a pattern with one of the following sequences:

Sequence	Description
(*BSR_ANYCRLF)	any of CR, LF or CRLF
(*BSR_UNICODE)	any Unicode newline sequence

Comments

It's possible to include comments inside a pattern. Comments do not participate in the pattern matching. Comments start at the `(?`

sequence and continue up to the next closing parenthesis:

```
SELECT 'ab12' RLIKE 'ab(?#expect digits)12';
-> 1
```

Quoting

POSIX uses the backslash to remove a special meaning from a character. PCRE introduces a syntax to remove special meaning from a sequence of characters. The characters inside `\Q` … `\E` are treated literally, without their special meaning.

This example checks if the string matches a dollar sign followed by a parenthesized name (a variable reference in some languages):

```
SELECT '$(abc)' RLIKE '^\\Q$(\\E\\w+\\Q)\\E$';
-> 1
```

Note that the leftmost dollar sign and the parentheses are used literally, while the rightmost dollar sign is still used to match the end of the string.

Resetting the Match Start

The escape sequence `\K` causes any previously matched characters to be excluded from the final matched sequence. For example, the pattern: `(foo)\Kbar` matches `foobar`, but reports that it has matched `bar`. This feature is similar to a look-behind assertion. However, in this case, the part of the subject before the real match does not have to be of fixed length:

```
SELECT REGEXP_SUBSTR('aaa123', '[a-z]*\\K[0-9]*');
-> 123
```

Non-Capturing Groups

The question mark and the colon after the opening parenthesis create a non-capturing group: `(?:...)`.

This example removes an optional article from a word, for example for better sorting of the results.

```
SELECT REGEXP_REPLACE('The King','(?:the|an|a)[^a-z]([a-z]+)','\\1');
-> King
```

Note that the articles are listed inside the left parentheses using the alternation operator `|` but they do not produce a captured subpattern, so the word followed by the article is referenced by `'1'` in the third argument to the function. Using non-capturing groups can be useful to save numbers on the sup-patterns that won't be used in the third argument of REGEXP_REPLACE(), as well as for performance purposes.

Non-Greedy Quantifiers

By default, the repetition quantifiers `?`, `*`, `+` and `{n,m}` are "greedy", that is, they try to match as much as possible. Adding a question mark after a repetition quantifier makes it "non-greedy", so the pattern matches the minimum number of times possible.

This example cuts C comments from a line:

```
SELECT REGEXP_REPLACE('/* Comment1 */ i+= 1; /* Comment2 */', '/[*].*?[*]/','');
->  i+= 1;
```

The pattern without the non-greedy flag to the quantifier `/[*].*[*]/` would match the entire string between the leftmost `/*` and the rightmost `*/`.

Atomic Groups

A sequence inside `(?>`…`)` makes an atomic group. Backtracking inside an atomic group is prevented once it has matched; however, backtracking past to the previous items works normally.

Consider the pattern `\d+foo` applied to the subject string `123bar`. Once the engine scans `123` and fails on the letter `b`, it would normally backtrack to `2` and try to match again, then fail and backtrack to `1` and try to match and fail again, and finally fail the entire pattern. In case of an atomic group `(?>\d+)foo` with the same subject string `123bar`, the engine gives up immediately after the first failure to match `foo`. An atomic group with a quantifier can match all or nothing.

Atomic groups produce faster false results (i.e. in case when a long subject string does not match the pattern), because the regexp engine saves performance on backtracking. However, don't hurry to put everything into atomic groups. This example demonstrates the difference between atomic and non-atomic match:

```
SELECT 'abcc' RLIKE 'a(?>bc|b)c' AS atomic1;
-> 1

SELECT 'abc' RLIKE 'a(?>bc|b)c' AS atomic2;
-> 0

SELECT 'abcc' RLIKE 'a(bc|b)c' AS non_atomic1;
-> 1

SELECT 'abc' RLIKE 'a(bc|b)c' AS non_atomic2;
-> 1
```

The non-atomic pattern matches both `abbc` and `abc`, while the atomic pattern matches `abbc` only.

The atomic group `(?>bc|b)` in the above example can be "translated" as "if there is `bc`, then don't try to match as `b`". So `b` can match only if `bc` is not found.

Atomic groups are not capturing. To make an atomic group capturing, put it into parentheses:

```
SELECT REGEXP_REPLACE('abcc','a((?>bc|b))c','\\1');
-> bc
```

Possessive quantifiers

An atomic group which ends with a quantifier can be rewritten using a so called "possessive quantifier" syntax by putting an additional `+` sign following the quantifier.

The pattern `(?>\d+)foo` from the previous section's example can be rewritten as `\d++foo`.

Absolute and Relative Numeric Backreferences

Backreferences match the same text as previously matched by a capturing group. Backreferences can be written using:

- a backslash followed by a digit
- the `\g` escape sequence followed by a positive or negative number
- the `\g` escape sequence followed by a positive or negative number enclosed in braces

The following backreferences are identical and refer to the first capturing group:

- `\1`
- `\g1`
- `\g{1}`

This example demonstrates a pattern that matches "sense and sensibility" and "response and responsibility", but not "sense and responsibility":

```
SELECT 'sense and sensibility' RLIKE '(sens|respons)e and \\1ibility';
-> 1
```

This example removes doubled words that can unintentionally creep in when you edit a text in a text editor:

```
SELECT REGEXP_REPLACE('using using the the regexp regexp',
 '\\b(\\w+)\\s+\\1\\b','\\1');
-> USING the regexp
```

Note that all double words were removed, in the beginning, in the middle and in the end of the subject string.

A negative number in a `\g` sequence means a relative reference. Relative references can be helpful in long patterns, and also in patterns that are created by joining fragments together that contain references within

themselves. The sequence `\g{-1}` is a reference to the most recently started capturing subpattern before `\g`.

In this example `\g{-1}` is equivalent to `\2`:

```
SELECT 'abc123def123' RLIKE '(abc(123)def)\\g{-1}';
-> 1

SELECT 'abc123def123' RLIKE '(abc(123)def)\\2';
-> 1
```

Named Subpatterns and Backreferences

Using numeric backreferences for capturing groups can be hard to track in a complicated regular expression. Also, the numbers can change if an expression is modified. To overcome these difficulties, PCRE supports named subpatterns.

A subpattern can be named in one of three ways: `(?<name>…)` or `(?'name'…)` as in Perl, or `(?P<name>…)` as in Python. References to capturing subpatterns from other parts of the pattern, can be made by name as well as by number.

Backreferences to a named subpattern can be written using the .NET syntax `\k{name}`, the Perl syntax `\k<name>` or `\k'name'` or `\g{name}`, or the Python syntax `(?P=name)`.

This example tests if the string is a correct HTML tag:

```
SELECT '<a href="../">Up</a>' RLIKE '<(?<tag>[a-z][a-z0-9]*)[^>]*>[^<]*</(?P=tag)>';
-> 1
```

Positive and Negative Look-Ahead and Look-Behind Assertions

Look-ahead and look-behind assertions serve to specify the context for the searched regular expression pattern. Note that the assertions only check the context, they do not capture anything themselves!

This example finds the letter which is not followed by another letter (negative look-ahead):

```
SELECT REGEXP_SUBSTR('ab1','[a-z](?![a-z])');
-> b
```

This example finds the letter which is followed by a digit (positive look-ahead):

```
SELECT REGEXP_SUBSTR('ab1','[a-z](?=[0-9])');
-> b
```

This example finds the letter which does not follow a digit character (negative look-behind):

```
SELECT REGEXP_SUBSTR('1ab','(?<![0-9])[a-z]');
-> b
```

This example finds the letter which follows another letter character (positive look-behind):

```
SELECT REGEXP_SUBSTR('1ab','(?<=[a-z])[a-z]');
-> b
```

Note that look-behind assertions can only be of fixed length; you cannot have repetition operators or alternations with different lengths:

```
SELECT 'aaa' RLIKE '(?<=(a|bc))a';
ERROR 1139 (42000): Got error 'lookbehind assertion is not fixed length at offset 10' from regexp
```

Subroutine Reference and Recursive Patterns

PCRE supports a special syntax to recourse the entire pattern or its individual subpatterns:

Syntax	Description
(?R)	Recourse the entire pattern
(?n)	call subpattern by absolute number
(?+n)	call subpattern by relative number
(?-n)	call subpattern by relative number
(?&name)	call subpattern by name (Perl)
(?P>name)	call subpattern by name (Python)
\g	call subpattern by name (Oniguruma)
\g'name'	call subpattern by name (Oniguruma)
\g	call subpattern by absolute number (Oniguruma)
\g'n'	call subpattern by absolute number (Oniguruma)
\g<+n>	call subpattern by relative number
\g<-n>	call subpattern by relative number
\g'+n'	call subpattern by relative number
\g'-n'	call subpattern by relative number

This example checks for a correct additive arithmetic expression consisting of numbers, unary plus and minus, binary plus and minus, and parentheses:

```
SELECT '1+2-3+(+(4-1)+(-2)+(+1))' RLIKE  '^(([+-]?(\\d+|[(](?1)[)]))(([+-](?1))*))$';
-> 1
```

The recursion is done using `(?1)` to call for the first parenthesized subpattern, which includes everything except the leading `^` and the trailing `$`.

The regular expression in the above example implements the following BNF grammar:

1. `<expression> ::= <term> [(<sign> <term>)...]`
2. `<term> ::= [ <sign> ] <primary>`
3. `<primary> ::= <number> | <left paren> <expression> <right paren>`
4. `<sign> ::= <plus sign> | <minus sign>`

Defining Subpatterns For Use By Reference

Use the `(?(DEFINE)…)` syntax to define subpatterns that can be referenced from elsewhere.

This example defines a subpattern with the name `letters` that matches one or more letters, which is further reused two times:

```
SELECT 'abc123xyz' RLIKE '^(?(DEFINE)(?<letters>[a-z]+))(?&letters)[0-9]+(?&letters)$';
-> 1
```

The above example can also be rewritten to define the digit part as a subpattern as well:

```
SELECT 'abc123xyz' RLIKE
 '^(?(DEFINE)(?<letters>[a-z]+)(?<digits>[0-9]+))(?&letters)(?&digits)(?&letters)$';
-> 1
```

Conditional Subpatterns

There are two forms of conditional subpatterns:

```
(?(condition)yes-pattern)
(?(condition)yes-pattern|no-pattern)
```

The `yes-pattern` is used if the condition is satisfied, otherwise the `no-pattern` (if any) is used.

Conditions With Subpattern References

If a condition consists of a number, it makes a condition with a subpattern reference. Such a condition is true if a capturing subpattern corresponding to the number has previously matched.

This example finds an optionally parenthesized number in a string:

```
SELECT REGEXP_SUBSTR('a(123)b', '([(])?[0-9]+(?(1)[)])');
-> (123)
```

The `([(])?` part makes a capturing subpattern that matches an optional opening parenthesis; the `[0-9]+` part matches a number, and the `(?(1)[)])` part matches a closing parenthesis, but only if the opening parenthesis has been previously found.

Other Kinds of Conditions

The other possible condition kinds are: recursion references and assertions. See the PCRE documentation for details.

Matching Zero Bytes (0x00)

PCRE correctly works with zero bytes in the subject strings:

```
SELECT 'a\0b' RLIKE '^a.b$';
-> 1
```

Zero bytes, however, are not supported literally in the pattern strings and should be escaped using the `\xhh` or `\x{hh}` syntax:

```
SELECT 'a\0b' RLIKE '^a\\x{00}b$';
-> 1
```

Other PCRE Features

PCRE provides other extended features that were not covered in this document, such as duplicate subpattern numbers, backtracking control, breaking utf-8 sequences into individual bytes, setting the match limit, setting the recursion limit, optimization control, recursion conditions, assertion conditions and more types of extended grapheme clusters. Please refer to the PCRE documentation for details.

Enhanced regex was implemented as a GSoC 2013 project by Sudheera Palihakkara.

default_regex_flags Examples

The default_regex_flags variable was introduced to address the remaining incompatibilities between PCRE and the old regex library. Here are some examples of its usage:

The default behaviour (multiline match is off)

```
SELECT 'a\nb\nc' RLIKE '^b$';
+--------------------------+
| '(?m)a\nb\nc' RLIKE '^b$' |
+--------------------------+
|                        0 |
+--------------------------+
```

Enabling the multiline option using the PCRE option syntax:

```
SELECT 'a\nb\nc' RLIKE '(?m)^b$';
+-------------------------+
| 'a\nb\nc' RLIKE '(?m)^b$' |
+-------------------------+
|                       1 |
+-------------------------+
```

Enabling the miltiline option using default_regex_flags

```
SET default_regex_flags='MULTILINE';
SELECT 'a\nb\nc' RLIKE '^b$';
+----------------------+
| 'a\nb\nc' RLIKE '^b$' |
+----------------------+
|                    1 |
+----------------------+
```

REGEXP

Syntax

```
expr REGEXP pat, expr RLIKE pat
```

Description

Performs a pattern match of a string expression `expr` against a pattern `pat`. The pattern can be an extended regular expression. See Regular Expressions Overview for details on the syntax for regular expressions (see also PCRE Regular Expressions).

Returns `1` if `expr` matches `pat` or `0` if it doesn't match. If either `expr` or `pat` are `NULL`, the result is `NULL`.

The negative form NOT REGEXP also exists, as an alias for `NOT (string REGEXP pattern)`. `RLIKE` and `NOT RLIKE` are synonyms for `REGEXP` and `NOT REGEXP`, originally provided for mSQL compatibility.

The pattern need not be a literal string. For example, it can be specified as a string expression or table column.

Note: Because MariaDB uses the C escape syntax in strings (for example, "\n" to represent the newline character), you must double any "" that you use in your `REGEXP` strings.

`REGEXP` is not case sensitive, except when used with binary strings.

The default_regex_flags variable addresses the remaining compatibilities between PCRE and the old regex library.

Examples

```
SELECT 'Monty!' REGEXP 'm%y%%';
+-------------------------+
| 'Monty!' REGEXP 'm%y%%' |
+-------------------------+
|                       0 |
+-------------------------+

SELECT 'Monty!' REGEXP '.*';
+----------------------+
| 'Monty!' REGEXP '.*' |
+----------------------+
|                    1 |
+----------------------+

SELECT 'new*\n*line' REGEXP 'new\\*.\\*line';
+---------------------------------------+
| 'new*\n*line' REGEXP 'new\\*.\\*line' |
+---------------------------------------+
|                                     1 |
+---------------------------------------+

SELECT 'a' REGEXP 'A', 'a' REGEXP BINARY 'A';
+----------------+-----------------------+
| 'a' REGEXP 'A' | 'a' REGEXP BINARY 'A' |
+----------------+-----------------------+
|              1 |                     0 |
+----------------+-----------------------+

SELECT 'a' REGEXP '^[a-d]';
+--------------------+
| 'a' REGEXP '^[a-d]' |
+--------------------+
|                  1 |
+--------------------+
```

default_regex_flags examples

MariaDB uses the default_regex_flags variable to address the remaining compatibilities between PCRE and the old regex library.

The default behavior (multiline match is off)

```
SELECT 'a\nb\nc' RLIKE '^b$';
+---------------------------+
| '(?m)a\nb\nc' RLIKE '^b$' |
+---------------------------+
|                         0 |
+---------------------------+
```

Enabling the multiline option using the PCRE option syntax:

```
SELECT 'a\nb\nc' RLIKE '(?m)^b$';
+---------------------------+
| 'a\nb\nc' RLIKE '(?m)^b$' |
+---------------------------+
|                         1 |
+---------------------------+
```

Enabling the multiline option using default_regex_flags

```
SET default_regex_flags='MULTILINE';
SELECT 'a\nb\nc' RLIKE '^b$';
+-----------------------+
| 'a\nb\nc' RLIKE '^b$' |
+-----------------------+
|                     1 |
+-----------------------+
```

REGEXP_INSTR

Syntax

```
REGEXP_INSTR(subject, pattern)
```

Returns the position of the first occurrence of the regular expression `pattern` in the string `subject`, or 0 if pattern was not found.

The positions start with 1 and are measured in characters (i.e. not in bytes), which is important for multi-byte character sets. You can cast a multi-byte character set to BINARY to get offsets in bytes.

The function follows the case sensitivity rules of the effective collation. Matching is performed case insensitively for case insensitive collations, and case sensitively for case sensitive collations and for binary data.

The collation case sensitivity can be overwritten using the (?i) and (?-i) PCRE flags.

MariaDB uses the PCRE regular expression library for enhanced regular expression performance, and `REGEXP_INSTR` was introduced as part of this enhancement.

Examples

```
SELECT REGEXP_INSTR('abc','b');
-> 2

SELECT REGEXP_INSTR('abc','x');
-> 0

SELECT REGEXP_INSTR('BJÖRN','N');
-> 5
```

Casting a multi-byte character set as BINARY to get offsets in bytes:

```
SELECT REGEXP_INSTR(BINARY 'BJÖRN','N') AS cast_utf8_to_binary;
-> 6
```

Case sensitivity:

```
SELECT REGEXP_INSTR('ABC','b');
-> 2

SELECT REGEXP_INSTR('ABC' COLLATE utf8_bin,'b');
-> 0

SELECT REGEXP_INSTR(BINARY'ABC','b');
-> 0

SELECT REGEXP_INSTR('ABC','(?-i)b');
-> 0

SELECT REGEXP_INSTR('ABC' COLLATE utf8_bin,'(?i)b');
-> 2
```

This page is licensed: CC BY-SA / Gnu FDL

REGEXP_REPLACE

Syntax

```
REGEXP_REPLACE(subject, pattern, replace)
```

Description

`REGEXP_REPLACE` returns the string `subject` with all occurrences of the regular expression `pattern` replaced by the string `replace`. If no occurrences are found, then `subject` is returned as is.

The replace string can have backreferences to the subexpressions in the form \N, where N is a number from 1 to 9.

The function follows the case sensitivity rules of the effective collation. Matching is performed case insensitively for case insensitive collations, and case sensitively for case sensitive collations and for binary data.

The collation case sensitivity can be overwritten using the (?i) and (?-i) PCRE flags.

MariaDB uses the PCRE regular expression library for enhanced regular expression performance, and `REGEXP_REPLACE` was introduced as part of this enhancement.

The default_regex_flags variable addresses the remaining compatibilities between PCRE and the old regex library.

Examples

```
SELECT REGEXP_REPLACE('ab12cd','[0-9]','') AS remove_digits;
-> abcd

SELECT REGEXP_REPLACE('<html><head><title>title</title><body>body</body></htm>', '<.+?>',' ')
AS strip_html;
-> title  body
```

Backreferences to the subexpressions in the form , where N is a number from 1 to 9:

```
SELECT REGEXP_REPLACE('James Bond','^(.*) (.*)$','\\2, \\1') AS reorder_name;
-> Bond, James
```

Case insensitive and case sensitive matches:

```
SELECT REGEXP_REPLACE('ABC','b','-') AS case_insensitive;
-> A-C

SELECT REGEXP_REPLACE('ABC' COLLATE utf8_bin,'b','-') AS case_sensitive;
-> ABC

SELECT REGEXP_REPLACE(BINARY 'ABC','b','-') AS binary_data;
-> ABC
```

Overwriting the collation case sensitivity using the (?i) and (?-i) PCRE flags.

```
SELECT REGEXP_REPLACE('ABC','(?-i)b','-') AS force_case_sensitive;
-> ABC

SELECT REGEXP_REPLACE(BINARY 'ABC','(?i)b','-') AS force_case_insensitive;
-> A-C
```

This page is licensed: CC BY-SA / Gnu FDL

REGEXP_SUBSTR

Syntax

```
REGEXP_SUBSTR(subject,pattern)
```

Description

Returns the part of the string `subject` that matches the regular expression `pattern`, or an empty string if `pattern` was not found.

The function follows the case sensitivity rules of the effective collation. Matching is performed case insensitively for case insensitive collations, and case sensitively for case sensitive collations and for binary data.

The collation case sensitivity can be overwritten using the (?i) and (?-i) PCRE flags.

MariaDB uses the PCRE regular expression library for enhanced regular expression performance, and `REGEXP_SUBSTR` was introduced as part of this enhancement.

The default_regex_flags variable addresses the remaining compatibilities between PCRE and the old regex library.

Examples

```
SELECT REGEXP_SUBSTR('ab12cd','[0-9]+');
-> 12

SELECT REGEXP_SUBSTR(
  'See https://mariadb.org/en/foundation/ for details',
  'https?://[^/]*');
-> https://mariadb.org
```

This page is licensed: CC BY-SA / Gnu FDL

RLIKE

Syntax

```
expr REGEXP pat, expr RLIKE pat
```

Description

`RLIKE` is a synonym for REGEXP.

This page is licensed: CC BY-SA / Gnu FDL

VEC_DISTANCE

> **Note:**
>
> Vectors are available from MariaDB Community Server 11.7 and from MariaDB Enterprise Server 11.4.5-3.

Syntax

```
VEC_DISTANCE(v, s)
```

Description

`VEC_DISTANCE` is a generic function that behaves either as VEC_DISTANCE_EUCLIDEAN, calculating the Euclidean (L2) distance between two points. Or VEC_DISTANCE_COSINE, calculating the Cosine distance between two vectors, depending on the underlying index type.

If the underlying index cannot be determined, an error 4206 is returned:

```
ERROR 4206 (HY000): Cannot determine distance type for VEC_DISTANCE, index is not found
```

Example

```
INSERT INTO v VALUES
     (1, x'e360d63ebe554f3fcdbc523f4522193f5236083d'),
     (2, x'f511303f72224a3fdd05fe3eb22a133ffae86a3f'),

VEC_DISTANCE_COSINE

> **Note:**
>
> Vectors are available from MariaDB Community Server 11.7 and from MariaDB Enterprise Server 11.4.5-3.

Syntax

```
VEC_DISTANCE_COSINE(v, s)
```

Description

`VEC_Distance_Cosine` is an SQL function that calculates the Cosine distance between two (not necessarily normalized) vectors.

Vectors must be of the same length. A distance between two vectors of different lengths is not defined, and `VEC_Distance_Cosine` will return `NULL` in such cases.

If the vector index was not built for the cosine function (see CREATE TABLE with Vectors), the index is not used — a full table scan is performed instead. The VEC_DISTANCE function is a generic function that behaves either as VEC_DISTANCE_EUCLIDEAN or `VEC_DISTANCE_COSINE`, depending on the underlying index type.

Example

```
SELECT VEC_DISTANCE_COSINE(vec_fromtext('[1,2,3]'), vec_fromtext('[3,5,7]'));
+-----------------------------------------------------------------------+
| VEC_DISTANCE_COSINE(vec_fromtext('[1,2,3]'), vec_fromtext('[3,5,7]')) |
+-----------------------------------------------------------------------+
|                                                  0.00258509695694209 |
+-----------------------------------------------------------------------+
```

VEC_DISTANCE_EUCLIDEAN

> **Note:**
>
> Vectors are available from MariaDB Community Server 11.7 and from MariaDB Enterprise Server 11.4.5-3.

Syntax

```
VEC_DISTANCE_EUCLIDEAN(v, s)
```

Description

`VEC_Distance_Euclidean` is an SQL function that calculates a Euclidean (L2) distance between two points.

Vectors must be of the same length, a distance between two vectors of different lengths is not defined and `VEC_Distance_Euclidean` returns `NULL` in such cases.

If the vector index was not built for the euclidean function (see CREATE TABLE with Vectors), the index is not used, and a full table scan performed instead. The VEC_DISTANCE function is a generic function that behaves either as `VEC_DISTANCE_EUCLIDEAN` or VEC_DISTANCE_COSINE, depending on the underlying index type.

Example

```
INSERT INTO v VALUES
     (1, x'e360d63ebe554f3fcdbc523f4522193f5236083d'),
     (2, x'f511303f72224a3fdd05fe3eb22a133ffae86a3f'),
     (3,x'f09baa3ea172763f123def3e0c7fe53e288bf33e'),
     (4,x'b97a523f2a193e3eb4f62e3f2d23583e9dd60d3f'),
     (5,x'f7c5df3e984b2b3e65e59d3d7376db3eac63773e'),
     (6,x'de01453ffa486d3f10aa4d3fdd66813c71cb163f'),
     (7,x'76edfc3e4b57243f10f8423fb158713f020bda3e'),
     (8,x'56926c3fdf098d3e2c8c5e3d1ad4953daa9d0b3e'),
     (9,x'7b713f3e5258323f80d1113d673b2b3f66e3583f'),
     (10,x'6ca1d43e9df91b3fe580da3e1c247d3f147cf33e');

SELECT id FROM v
  ORDER BY VEC_Distance_Euclidean(v, x'6ca1d43e9df91b3fe580da3e1c247d3f147cf33e') LIMIT 10;
+----+
| id |
+----+
| 10 |
|  7 |
|  3 |
|  9 |
|  2 |
|  1 |
|  5 |
|  4 |
|  6 |
|  8 |
+----+
```

Note:

The vector index is only used for nearest-neighbor search when the query combines `ORDER BY VEC_DISTANCE_EUCLIDEAN(...)` with a `LIMIT`. Without `LIMIT`, the distance is computed for every row (a full table scan). See Vector Overview.

VEC_FromText

> **Note:**
>
> Vectors are available from MariaDB Community Server 11.7 and from MariaDB Enterprise Server 11.4.5-3.

Syntax

```
VEC_FromText(s)
```

Description

`VEC_FromText` converts a text representation of the vector (json array of numbers) to a vector (little-endian IEEE float sequence of bytes, 4 bytes per float).

Example

```
SELECT HEX(vec_fromtext('[1,2,3]'));
+------------------------------+
| HEX(vec_fromtext('[1,2,3]')) |
+------------------------------+
| 0000803F0000004000004040     |
+------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

VEC_ToText

> **Note:**
>
> Vectors are available from MariaDB Community Server 11.7 and from MariaDB Enterprise Server 11.4.5-3.

Syntax

```
VEC_ToText(v)
```

Description

`VEC_ToText` converts a binary vector into a json array of numbers (floats). Returns `NULL` and throws a warning Error 4201 if given an invalid vector.

Example

```
SELECT VEC_ToText(x'e360d63ebe554f3fcdbc523f4522193f5236083d');
+-----------------------------------------------------------+
| VEC_ToText(x'e360d63ebe554f3fcdbc523f4522193f5236083d') |
+-----------------------------------------------------------+
| [0.418708,0.809902,0.823193,0.598179,0.033255]          |
+-----------------------------------------------------------+
```

Invalid vector:

```
SELECT VEC_ToText(x'aabbcc');
+-----------------------+
| VEC_ToText(x'aabbcc') |
+-----------------------+
| NULL                  |
+-----------------------+
1 row in set, 1 warning (0.000 sec)

Warning (Code 4201): Invalid binary vector format. Must use IEEE standard float
  representation in little-endian format. Use VEC_FromText() to generate it.
```

Data Type Storage Requirements

The following tables indicate the approximate data storage requirements for each data type.

Numeric Data Types

Data Type	Storage Requirement
TINYINT	1 byte
SMALLINT	2 bytes
MEDIUMINT	3 bytes
INT	4 bytes
BIGINT	8 bytes
FLOAT(p)	4 bytes if p <= 24, otherwise 8 bytes
DOUBLE	8 bytes
DECIMAL	See table below
BIT(M)	(M+7)/8 bytes

Note that `MEDIUMINT` columns will require 4 bytes in memory (for example, in InnoDB buffer pool).

Decimal

Decimals are stored using a binary format, with the integer and the fraction stored separately. Each nine-digit multiple requires 4 bytes, followed by a number of bytes for whatever remains, as follows:

Remaining digits	Storage Requirement
0	0 bytes
1	1 byte
2	1 byte
3	2 bytes
4	2 bytes
5	3 bytes
6	3 bytes
7	4 bytes
8	4 bytes

String Data Types

In the descriptions below, `M` is the declared column length (in characters or in bytes), while `len` is the actual length in bytes of the value.

Data Type	Storage Requirement
ENUM	1 byte for up to 255 enum values, 2 bytes for 256 to 65,535 enum values
CHAR(M)	M × w bytes, where w is the number of bytes required for the maximum-length character in the character set
BINARY(M)	M bytes
VARCHAR(M), VARBINARY(M)	len + 1 bytes if column is 0 – 255 bytes, len + 2 bytes if column may require more than 255 bytes
TINYBLOB, TINYTEXT	len + 1 bytes
BLOB, TEXT	len + 2 bytes
MEDIUMBLOB, MEDIUMTEXT	len + 3 bytes
LONGBLOB, LONGTEXT	len + 4 bytes
XMLTYPE	len + 4 bytes (same as LONGBLOB)
SET	Given M members of the set, (M+7)/8 bytes, rounded up to 1, 2, 3, 4, or 8 bytes
INET6	16 bytes
UUID	16 bytes

Note: Introduced in MariaDB 12.3, the `XMLTYPE` data type has a maximum storage capacity of 4GB, similar to `LONGBLOB`.

In some character sets, not all characters use the same number of bytes. utf8 encodes characters with one to three bytes per character, while `utf8mb4` requires one to four bytes per character.

When using field the `COMPRESSED` attribute, 1 byte is reserved for metadata. For example, `VARCHAR(255)` will use +2 bytes instead of +1.

Examples

Assuming a single-byte character-set:

Value	CHAR(2)	Storage Required	VARCHAR(2)	Storage Required
''	' '	2 bytes	''	1 byte
'1'	'1'	2 bytes	'1'	2 bytes
'12'	'12'	2 bytes	'12'	3 bytes

Date and Time Data Types

Data Type	Storage Requirement
DATE	3 bytes
TIME	3 bytes
DATETIME	8 bytes
TIMESTAMP	4 bytes
YEAR	1 byte

Microseconds

MariaDB defaults to the MySQL format (by means of the mysql56_temporal_format variable). Microseconds have the following additional storage requirements:

Precision	Storage Requirement
0	0 bytes
1,2	1 byte
3,4	2 bytes
5,6	3 bytes

NULL Values

For the InnoDB COMPACT, DYNAMIC and COMPRESSED row formats, a number of bytes will be allocated in the record header for the nullable fields. If there are between 1 and 8 nullable fields, 1 such byte will be allocated. In the record payload area, no space will be reserved for values that are `NULL`.

For the InnoDB REDUNDANT row format, the overhead is 1 bit in the record header (as a part of the 1-byte or 2-byte "end of field" pointer). In that format, a `NULL` fixed-length field will consume the same amount of space as any `NOT NULL` value in the record payload area. The motivation is that it is possible to update in place between `NOT NULL` and `NULL` values.

In other formats, `NULL` values usually require 1 bit in the data file, 1 byte in the index file.

AUTO_INCREMENT

Description

The `AUTO_INCREMENT` attribute can be used to generate a unique identity for new rows. When you insert a new record into the table (or upon adding an AUTO_INCREMENT attribute with the ALTER TABLE statement), and the `AUTO_INCREMENT` field is NULL or DEFAULT (in the case of an INSERT), automatically be incremented. This also applies to `0`, unless the NO_AUTO_VALUE_ON_ZERO SQL_MODE is enabled.

`AUTO_INCREMENT` columns start from 1 by default. The automatically generated value can never be lower than `0`.

Each table can have only one `AUTO_INCREMENT` column. It must defined as a key (not necessarily the `PRIMARY KEY` or `UNIQUE` key). In some storage engines (including the default InnoDB), if the key consists of multiple columns, the `AUTO_INCREMENT` column must be the first column. Storage engines that permit the column to be placed elsewhere are Aria, MyISAM, MERGE, Spider, BLACKHOLE, FederatedX and Federated.

```
CREATE TABLE animals (
     id MEDIUMINT NOT NULL AUTO_INCREMENT,
     name CHAR(30) NOT NULL,
     PRIMARY KEY (id)
 );

INSERT INTO animals (name) VALUES
    ('dog'),('cat'),('penguin'),
    ('fox'),('whale'),('ostrich');
```

```
SELECT * FROM animals;
+----+---------+
| id | name    |
+----+---------+
|  1 | dog     |
|  2 | cat     |
|  3 | penguin |
|  4 | fox     |
|  5 | whale   |
|  6 | ostrich |
+----+---------+
```

`SERIAL` is an alias for `BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE`.

```
CREATE TABLE t (id SERIAL, c CHAR(1)) ENGINE=InnoDB;

SHOW CREATE TABLE t \G
*************************** 1. row ***************************
       Table: t
Create Table: CREATE TABLE `t` (
  `id` bigint(20) unsigned NOT NULL AUTO_INCREMENT,
  `c` char(1) DEFAULT NULL,
  UNIQUE KEY `id` (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

Setting or Changing the Auto_Increment Value

You can use an ALTER TABLE statement to assign a new value to the `auto_increment` table option, or set the insert_id server system variable to change the next `AUTO_INCREMENT` value inserted by the current session.

LAST_INSERT_ID() can be used to see the last `AUTO_INCREMENT` value inserted by the current session.

```
ALTER TABLE animals AUTO_INCREMENT=8;

INSERT INTO animals (name) VALUES ('aardvark');

SELECT * FROM animals;
+----+-----------+
| id | name      |
+----+-----------+
|  1 | dog       |
|  2 | cat       |
|  3 | penguin   |
|  4 | fox       |
|  5 | whale     |
|  6 | ostrich   |
|  8 | aardvark  |
+----+-----------+

SET insert_id=12;

INSERT INTO animals (name) VALUES ('gorilla');

SELECT * FROM animals;
+----+-----------+
| id | name      |
+----+-----------+
|  1 | dog       |
|  2 | cat       |
|  3 | penguin   |
|  4 | fox       |
|  5 | whale     |
|  6 | ostrich   |
|  8 | aardvark  |
| 12 | gorilla   |
+----+-----------+
```

InnoDB

`AUTO_INCREMENT` is persistent in InnoDB.

See also AUTO_INCREMENT Handling in InnoDB.

Setting Explicit Values

It is possible to specify a value for an `AUTO_INCREMENT` column. If the key is primary or unique, the value must not already exist in the key.

If the new value is higher than the current maximum value, the `AUTO_INCREMENT` value is updated, so the next value will be higher. If the new value is lower than the current maximum value, the `AUTO_INCREMENT` value remains unchanged.

The following example demonstrates these behaviors:

```
CREATE TABLE t (id INTEGER UNSIGNED AUTO_INCREMENT PRIMARY KEY) ENGINE = InnoDB;

INSERT INTO t VALUES (NULL);
SELECT id FROM t;
+----+
| id |
+----+
|  1 |
+----+

INSERT INTO t VALUES (10); -- higher value
SELECT id FROM t;
+----+
| id |
+----+
|  1 |
| 10 |
+----+

INSERT INTO t VALUES (2); -- lower value
INSERT INTO t VALUES (NULL); -- auto value
SELECT id FROM t;
+----+
| id |
+----+
|  1 |
|  2 |
| 10 |
| 11 |
+----+
```

Warning:

The ARCHIVE storage engine does not allow to insert a value that is lower than the current maximum.

Missing Values

An `AUTO_INCREMENT` column normally has missing values. This happens because if a row is deleted, or an `AUTO_INCREMENT` value is explicitly updated, old values are never reused. The `REPLACE` statement also deletes a row, and its value is wasted. With InnoDB, values can be reserved by a transaction; but if the transaction fails (for example, because of a `ROLLBACK`) the reserved value will be lost.

Thus `AUTO_INCREMENT` values can be used to sort results in a chronological order, but not to create a numeric sequence.

Replication

To make master-master or Galera safe to use `AUTO_INCREMENT` , you should use the system variables auto_increment_increment and auto_increment_offset to generate unique values for each server.

```
SET @@auto_increment_increment=3;

SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 3     |
| auto_increment_offset    | 1     |
+--------------------------+-------+

CREATE TABLE t (c INT NOT NULL AUTO_INCREMENT PRIMARY KEY);

INSERT INTO t VALUES (NULL), (NULL), (NULL);

SELECT * FROM t;
+---+
| c |
+---+
| 1 |
| 4 |
| 7 |
+---+

CREATE TABLE t2 (c INT NOT NULL AUTO_INCREMENT PRIMARY KEY);

SET @@auto_increment_offset=2;

SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 3     |
| auto_increment_offset    | 2     |
+--------------------------+-------+

INSERT INTO t2 VALUES (NULL), (NULL), (NULL);

SELECT * FROM t2;
+---+
| c |
+---+
| 2 |
| 5 |
| 8 |
+---+
```

If `auto_increment_offset` is larger than `auto_increment_increment`, the value of `auto_increment_offset` is ignored, and the offset reverts to the default of 1 instead:

```
SET @@auto_increment_offset=5;

SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 3     |
| auto_increment_offset    | 5     |
+--------------------------+-------+

CREATE TABLE t3 (c INT NOT NULL AUTO_INCREMENT PRIMARY KEY);

INSERT INTO t3 VALUES (NULL), (NULL), (NULL);

SELECT * FROM t3;
+---+
| c |
+---+
| 1 |
| 4 |
| 5 |
+---+

+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 3     |
| auto_increment_offset    | 3     |
+--------------------------+-------+

INSERT INTO t4 VALUES (NULL), (NULL), (NULL);

SELECT * FROM t4;
+---+
| c |
+---+
| 3 |
| 6 |
| 9 |
+---+
```

Changing `auto_increment_increment` and `auto_incremenet_offset` when adding a new master to a multi-master setup

The purpose of auto_increment_increment and auto_increment_offset is to ensure that in a multi-master or multi-source setup, all masters generate unique values for `auto_increment` fields or for sequences with `INCREMENT=0`.

If `auto_increment_increment` is larger than the current number of masters, then one can configure the new master with the not used `auto_increment_offset`. The easiest way to add a new master is to stop all MariaDB servers, update `auto_increment_increment` and `auto_increment_offset` in the configuration files, and restart.\

This has to be done if `auto_increment_increment` is 1. If one has more than one master (`auto_increment_increment` > 1), there is a way to add more masters with only having to restart one of the masters. The 'trick' is to configure one of the masters to not use all the values in its current sequence.

The following example illustrates how to do it. Assume you have two masters, A and B.

In this case you will have auto_increment_increment=2 for both masters and A would have `auto_increment_offset=1` and B would have `auto_increment_offset=2`. For A, all `auto_increment` and generated sequence values will be odd.

```
1
3
5
7
```

For B, all values will be even:

```
2
4
6
8
```

See the Replication section above.

If we change `auto_increment_increment` from `2` to `4` in A, it will now generate values from this sequence:

```
1
5
9
13
```

As you can see, values `3`, `7`, `11` are not going to be used.We can get C to use values from this sequence by configuring `auto_increment_increment=4` and `auto_increment_offset=3`.

```
3
7
11
```

If we would like to add a 4'th master (D), we can do that by changing 'B' to use `auto_increment_increment=4` and then configure D to have `auto_increment_increment=4` and `auto_increment_offset=4`.

> **Note:**
>
> Note that when changing the `auto_increment_increment` or `auto_increment_offset` on a server, you have to either restart the server or ensure that all current connections are killed. This is needed to force all connections to use the new values.
>
> Also ensure that, if you want to use the above trick, you always double the value of `auto_increment_increment`. This is needed to ensure that the sequence used will not conflict with numbers generated by any other master.

CHECK Constraints, DEFAULT Values and Virtual Columns

`AUTO_INCREMENT` columns are not permitted in CHECK constraints, DEFAULT value expressions and virtual columns.

Generating Auto_Increment Values When Adding the Attribute

```
CREATE OR REPLACE TABLE t1 (a INT);
INSERT t1 VALUES (0),(0),(0);
ALTER TABLE t1 MODIFY a INT NOT NULL AUTO_INCREMENT PRIMARY KEY;
SELECT * FROM t1;
+---+
| a |
+---+
| 1 |
| 2 |
| 3 |
+---+
```

```
CREATE OR REPLACE TABLE t1 (a INT);
INSERT t1 VALUES (5),(0),(8),(0);
ALTER TABLE t1 MODIFY a INT NOT NULL AUTO_INCREMENT PRIMARY KEY;
SELECT * FROM t1;
+---+
| a |
+---+
| 5 |
| 6 |
| 8 |
| 9 |
+---+
```

If the NO_AUTO_VALUE_ON_ZERO SQL_MODE is set, zero values will not be automatically incremented:

```
SET SQL_MODE='no_auto_value_on_zero';
CREATE OR REPLACE TABLE t1 (a INT);
INSERT t1 VALUES (3), (0);
ALTER TABLE t1 MODIFY a INT NOT NULL AUTO_INCREMENT PRIMARY KEY;
SELECT * FROM t1;
+---+
| a |
+---+
| 0 |
| 3 |
+---+
```

AUTO_INCREMENT FAQ

How do I get the last inserted auto_increment value?

Use the LAST_INSERT_ID() function:

```
SELECT LAST_INSERT_ID();
```

What if someone else inserts before I select my id?

LAST_INSERT_ID() is connection specific, so there is no problem from race conditions.

How do I get the next value to be inserted?

You don't. Insert, then find out what you did with LAST_INSERT_ID().

How do I change what number auto_increment starts with?

Run a query, `ALTER TABLE yourTable AUTO_INCREMENT = x;` . The next insert will contain `x` or `MAX(autoField) + 1` , whichever is higher.

As an alternative, run `INSERT INTO yourTable (autoField) VALUES (x);` . The next insert will contain `x+1` or `MAX(autoField) + 1` , whichever is higher.

Issuing TRUNCATE TABLE will delete all the rows in the table, and will reset the auto_increment value to 0 in most cases.

How do I renumber rows once I deleted some in the middle?

Typically, you don't want to. Gaps are hardly ever a problem; if your application can't handle gaps in the sequence, you probably should rethink your application.

Can I do group-wise auto_increment?

Yes, if you use the MyISAM engine.

How do I get the AUTO_INCREMENT value in a BEFORE INSERT trigger?

This isn't possible. It's only available after insert.

How do I assign two fields the same auto_increment value in one query?

You can't, not even with an `AFTER INSERT` trigger. Insert, then go back and update using `LAST_INSERT_ID()` . Those two statements could be wrapped into one stored procedure if you wish.

However, you can mimic this behavior with a `BEFORE INSERT` trigger and a second table to store the sequence position:

```
CREATE TABLE sequence (table_name VARCHAR(255), position INT UNSIGNED);
INSERT INTO sequence VALUES ('testTable', 0);
CREATE TABLE testTable (firstAuto INT UNSIGNED, secondAuto INT UNSIGNED);
DELIMITER //
CREATE TRIGGER testTable_BI BEFORE INSERT ON testTable FOR EACH ROW BEGIN
  UPDATE sequence SET position = LAST_INSERT_ID(position + 1) WHERE table_name = 'testTable';
  SET NEW.firstAuto = LAST_INSERT_ID();
  SET NEW.secondAuto = LAST_INSERT_ID();
END//
DELIMITER ;
INSERT INTO testTable VALUES (NULL, NULL), (NULL, NULL);
SELECT * FROM testTable;

+-----------+------------+
| firstAuto | secondAuto |
+-----------+------------+
|         1 |          1 |
|         2 |          2 |
+-----------+------------+
```

The same sequence table can maintain separate sequences for multiple tables (or separate sequences for different fields in the same table) by adding extra rows.

Does the auto_increment field have to be primary key?

No, it only has to be indexed. It doesn't even have to be unique.

How does InnoDB handle AUTO_INCREMENT?

See AUTO_INCREMENT handling in InnoDB.

General Information To Read

AUTO_INCREMENT

Manual Notes

There can be only one `AUTO_INCREMENT` column per table, it must be indexed, and it cannot have a `DEFAULT` value. An `AUTO_INCREMENT` column works properly only if it contains only positive values. Inserting a negative number is regarded as inserting a very large positive number. This is done to avoid precision problems when numbers wrap over from positive to negative and also to ensure that you do not accidentally get an `AUTO_INCREMENT` column that contains 0.

How to start a table with a set AUTO_INCREMENT value?

```
CREATE TABLE autoinc_test (
  h INT UNSIGNED PRIMARY KEY AUTO_INCREMENT,
  m INT UNSIGNED
) AUTO_INCREMENT = 100;

INSERT INTO autoinc_test ( m ) VALUES ( 1 );

SELECT * FROM autoinc_test;
+-----+------+
| h   | m    |
+-----+------+
| 100 |    1 |
+-----+------+
```

NULL Values

`NULL` represents an unknown value. It is *not* an empty string (by default), or a zero value. These are all valid values, and are not `NULL` values.

When a table is created or the format altered, columns can be specified as accepting `NULL` values, or not accepting them, with the `NULL` and `NOT NULL` clauses respectively.

For example, a customer table could contain dates of birth. For some customers, this information is unknown, so the value could be `NULL`.

The same system could allocate a customer ID for each customer record, and in this case a `NULL` value would not be permitted.

```
CREATE TABLE customer (
 id INT NOT NULL,
 date_of_birth DATE NULL
...
)
```

User-defined variables are `NULL` until a value is explicitly assigned.

Stored routines parameters and local variables can always be set to `NULL`. If no `DEFAULT` value is specified for a local variable, its initial value will be `NULL`. If no value is assigned to an `OUT` parameter in a stored procedure, `NULL` is assigned at the end of the procedure.

Syntax

The case of `NULL` is not relevant. (uppercase) is an alias for `NULL`.

The IS operator accepts `UNKNOWN` as an alias for `NULL`, which is meant for boolean contexts.

Comparison Operators

`NULL` values cannot be used with most comparison operators. For example, =, >, >=, <=, <, or != cannot be used, as any comparison with a NULL always returns a NULL value, never true (1) or false (0).

```
SELECT NULL = NULL;
+-------------+
| NULL = NULL |
+-------------+
|        NULL |
+-------------+

SELECT 99 = NULL;
+-----------+
| 99 = NULL |
+-----------+
|      NULL |
+-----------+
```

To overcome this, certain operators are specifically designed for use with `NULL` values. To cater for testing equality between two values that may contain `NULL` values, there's <=>, `NULL`-safe equal.

```
SELECT 99 <=> NULL, NULL <=> NULL;
+-------------+---------------+
| 99 <=> NULL | NULL <=> NULL |
+-------------+---------------+
|           0 |             1 |
+-------------+---------------+
```

Other operators for working with `NULL` values include IS NULL and IS NOT NULL, ISNULL (for testing an expression) and COALESCE (for returning the first non-NULL parameter).

Ordering

When you order by a field that may contain `NULL` values, any `NULL` values are considered to have the lowest value. So ordering in `DESC` order will see the `NULL` values appearing last. To force `NULL` values to be regarded as highest values, one can add another column which has a higher value when the main field is `NULL`. Example:

```
SELECT col1 FROM tab ORDER BY ISNULL(col1), col1;
```

Descending order, with `NULL` values first:

```
SELECT col1 FROM tab ORDER BY IF(col1 IS NULL, 0, 1), col1 DESC;
```

All `NULL` values are also regarded as equivalent for the purposes of the `DISTINCT` and `GROUP BY` clauses.

Functions

In most cases, functions will return `NULL` if any of the parameters are NULL. There are also functions specifically for handling `NULL` values. These include IFNULL(), NULLIF() and COALESCE().

```
SELECT IFNULL(1,0);
+-------------+
| IFNULL(1,0) |
+-------------+
|           1 |
+-------------+

SELECT IFNULL(NULL,10);
+-----------------+
| IFNULL(NULL,10) |
+-----------------+
|              10 |
+-----------------+

SELECT COALESCE(NULL,NULL,1);
+-----------------------+
| COALESCE(NULL,NULL,1) |
+-----------------------+
|                     1 |
+-----------------------+
```

Aggregate functions, such as SUM and AVG ignore `NULL` values.

```
CREATE TABLE t(x INT);

INSERT INTO t VALUES (1),(9),(NULL);

SELECT SUM(x) FROM t;
+--------+
| SUM(x) |
+--------+
|     10 |
+--------+

SELECT AVG(x) FROM t;
+--------+
| AVG(x) |
+--------+
| 5.0000 |
+--------+
```

The one exception is COUNT(*), which counts rows, and doesn't look at whether a value is NULL or not. Compare for example, `COUNT(x)`, which ignores the `NULL`, and `COUNT(*)`, which counts it:

```
SELECT COUNT(x) FROM t;
+----------+
| COUNT(x) |
+----------+
|        2 |
+----------+

SELECT COUNT(*) FROM t;
+----------+
| COUNT(*) |
+----------+
|        3 |
+----------+
```

AUTO_INCREMENT, TIMESTAMP and Virtual Columns

MariaDB handles `NULL` values in a special way if the field is an AUTO_INCREMENT, a TIMESTAMP or a virtual column. Inserting a `NULL` value into a numeric `AUTO_INCREMENT` column will result in the next number in the auto increment sequence being inserted instead. This technique is frequently used with `AUTO_INCREMENT` fields, which are left to take care of themselves.

```
CREATE TABLE t2(id INT PRIMARY KEY AUTO_INCREMENT, letter CHAR(1));

INSERT INTO t2(letter) VALUES ('a'),('b');

SELECT * FROM t2;
+----+--------+
| id | letter |
+----+--------+
|  1 | a      |
|  2 | b      |
+----+--------+
```

Similarly, if a `NULL` value is assigned to a `TIMESTAMP` field, the current date and time is assigned instead.

```
CREATE TABLE t3 (x INT, ts TIMESTAMP);

INSERT INTO t3(x) VALUES (1),(2);
```

After a pause:

```
INSERT INTO t3(x) VALUES (3);

SELECT* FROM t3;
+------+---------------------+
| x    | ts                  |
+------+---------------------+
|    1 | 2013-09-05 10:14:18 |
|    2 | 2013-09-05 10:14:18 |
|    3 | 2013-09-05 10:14:29 |
+------+---------------------+
```

If a `NULL` is assigned to a `VIRTUAL` or `PERSISTENT` column, the default value is assigned instead.

```
CREATE TABLE virt (c INT, v INT AS (c+10) PERSISTENT) ENGINE=InnoDB;

INSERT INTO virt VALUES (1, NULL);

SELECT c, v FROM virt;
+------+------+
| c    | v    |
+------+------+
|    1 |   11 |
+------+------+
```

In all these special cases, `NULL` is equivalent to the `DEFAULT` keyword.

Inserting

If a `NULL` value is single-row inserted into a column declared as `NOT NULL`, an error will be returned. However, if the SQL mode is not strict (strict is the default), if a `NULL` value is multi-row inserted into a column declared as `NOT NULL`, the implicit default for the column type will be inserted (and `NOT` the default value in the table definition). The implicit defaults are an empty string for string types, and the zero value for numeric, date and time types.

By default, both cases will result in an error.

Examples

```
CREATE TABLE nulltest (
  a INT(11),
  x VARCHAR(10) NOT NULL DEFAULT 'a',
  y INT(11) NOT NULL DEFAULT 23
);
```

Single-row insert:

```
INSERT INTO nulltest (a,x,y) VALUES (1,NULL,NULL);
ERROR 1048 (23000): Column 'x' cannot be null
```

Multi-row insert with SQL mode not strict:

```
show variables like 'sql_mode%';
+---------------+--------------------------------------------+
| Variable_name | Value                                      |
+---------------+--------------------------------------------+
| sql_mode      | NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION |
+---------------+--------------------------------------------+

INSERT INTO nulltest (a,x,y) VALUES (1,NULL,NULL),(2,NULL,NULL);
Query OK, 2 rows affected, 4 warnings (0.08 sec)
Records: 2  Duplicates: 0  Warnings: 4
```

The specified defaults have not been used; rather, the implicit column type defaults have been inserted.

```
SELECT * FROM nulltest;
+------+---+---+
| a    | x | y |
+------+---+---+
|    1 |   | 0 |
|    2 |   | 0 |
+------+---+---+
```

Primary Keys and UNIQUE Indexes

`UNIQUE` indexes can contain multiple `NULL` values. Primary keys are never nullable.

Oracle Compatibility

In Oracle mode, `NULL` can be used as a statement:

```
IF a=10 THEN NULL; ELSE NULL; END IF
```

In Oracle mode, CONCAT and the Logical OR operator || ignore null.

When setting sql_mode=EMPTY_STRING_IS_NULL, empty strings and `NULL` values are the same thing.

For example:

```
SET sql_mode=EMPTY_STRING_IS_NULL;
SELECT '' IS NULL; -- returns TRUE
INSERT INTO t1 VALUES (''); -- inserts NULL
```

ROW TYPE OF

Overview

This is special declaration only available inside a stored procedure.

EXAMPLES

```
CREATE TABLE rowtypeof_table(
  descr VARCHAR(20),
  val INT
);
```

```
INSERT INTO rowtypeof_table VALUES ('Life', 42);
```

```
DELIMITER $$
CREATE PROCEDURE rowtypeof_proc()
BEGIN
  DECLARE rec1 ROW TYPE OF rowtypeof_table;
  SELECT * INTO rec1 FROM rowtypeof_table;
  SELECT rec1.descr, rec1.val;
END;
$$
DELIMITER ;
```

```
CALL rowtypeof_proc();

+------------+----------+
| rec1.descr | rec1.val |
+------------+----------+
| Life       |       42 |
+------------+----------+
```

This page is: Copyright © 2026 MariaDB. All rights reserved.

SERIAL

Overview

This is an alias for `BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE`.

EXAMPLES

```
CREATE TABLE serial_example (
  id SERIAL,
  data VARCHAR(32)
);
```

```
SHOW CREATE TABLE serial_example\G
```

```
*************************** 1. row ***************************
       Table: serial_example
Create Table: CREATE TABLE `serial_example` (
  `id` bigint(20) unsigned NOT NULL AUTO_INCREMENT,
  `data` varchar(32) DEFAULT NULL,
  UNIQUE KEY `id` (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

Numeric Data Types

See Numeric Data Type Overview.

General introduction to numeric data types. This page summarizes the available integer, fixed-point, and floating-point types and their storage characteristics.

See BIGINT.

Large integer type. A BIGINT uses 8 bytes and can store values from -9223372036854775808 to 9223372036854775807 (signed) or 0 to 18446744073709551615 (unsigned).

See BIT.

Bit-field data type. A BIT(M) column stores M bits per value, allowing storage of binary values from 1 to 64 bits in length.

See BOOL.

Synonym for TINYINT(1). This type is commonly used to represent boolean values, where 0 is considered false and non-zero values are true.

See BOOLEAN.

Complete BOOLEAN type reference: TINYINT(1) synonym, TRUE/FALSE aliases, CREATE TABLE/SHOW CREATE TABLE output, and IF()/IS operator evaluation.

See DEC, NUMERIC, FIXED.

Synonyms for DECIMAL. These keywords declare fixed-point numbers, which store exact numeric data with a defined precision and scale.

See DEC.

Synonym for DECIMAL. This keyword creates a fixed-point column with exact precision, suitable for financial calculations.

See DECIMAL.

Complete DECIMAL type reference: DECIMAL(M,D) syntax, precision limits (M≤65, D≤38), SIGNED/UNSIGNED/ZEROFILL options, and rounding behavior.

See DOUBLE PRECISION.

Synonym for DOUBLE. This keyword declares a normal-size (8-byte) floating-point number with double precision.

See DOUBLE.

Double precision floating-point number. A DOUBLE column uses 8 bytes to store large or precise approximate values.

See FIXED.

Synonym for DECIMAL. This keyword is used to define columns that require exact numeric precision, such as currency.

See FLOAT.

Single precision floating-point number. A FLOAT column uses 4 bytes and stores approximate values with less precision than DOUBLE.

See FLOAT4.

Synonym for FLOAT. This keyword declares a single-precision floating-point column.

See FLOAT8.

Synonym for DOUBLE. This keyword declares a double-precision floating-point column.

See Floating-point Accuracy.

Explanation of floating-point precision issues. This page details why FLOAT and DOUBLE types are approximate and how rounding errors occur.

See INT.

Complete INT type reference: INT(M) syntax, signed (-2147483648 to 2147483647) vs unsigned (0 to 4294967295) ranges, and ZEROFILL padding guidelines.

See INT1.

Synonym for TINYINT. This type uses 1 byte of storage.

See INT2.

Synonym for SMALLINT. This type uses 2 bytes of storage.

See INT3.

Synonym for MEDIUMINT. This type uses 3 bytes of storage.

See INT4.

Synonym for INT. This type uses 4 bytes of storage.

See INT8.

Synonym for BIGINT. This type uses 8 bytes of storage.

See INTEGER.

Synonym for INT. This keyword declares a standard 4-byte integer column.

See MEDIUMINT.

Medium-sized integer. A MEDIUMINT column uses 3 bytes and stores values from -8388608 to 8388607 (signed) or 0 to 16777215 (unsigned).

See MIDDLEINT.

Synonym for MEDIUMINT. This keyword refers to the 3-byte integer type.

See NUMBER.

Oracle-compatible synonym for DECIMAL. This type is used for fixed-point arithmetic.

See NUMERIC.

Synonym for DECIMAL. This type stores exact numeric data values.

See REAL.

Synonym for DOUBLE. In standard SQL mode, REAL is a double-precision floating-point number.

See SMALLINT.

Small integer type. A SMALLINT column uses 2 bytes and stores values from -32768 to 32767 (signed) or 0 to 65535 (unsigned).

See TINYINT.

Very small integer type. A TINYINT column uses 1 byte and stores values from -128 to 127 (signed) or 0 to 255 (unsigned).

This page is licensed: CC BY-SA / Gnu FDL

Numeric Data Type Overview

There are a number of numeric data types:

- BOOLEAN - Synonym for TINYINT(1)

- INT1 - Synonym for TINYINT
- INT2 - Synonym for SMALLINT
- INT3 - Synonym for MEDIUMINT
- INT, INTEGER
- INT4 - Synonym for INT
- INT8 - Synonym for BIGINT
- TINYINT
- SMALLINT
- MEDIUMINT
- BIGINT
- DECIMAL, DEC, NUMERIC, FIXED
- FLOAT
- DOUBLE, DOUBLE PRECISION, REAL
- BIT
- VECTOR

See the specific articles for detailed information on each.

SIGNED, UNSIGNED and ZEROFILL

Most numeric types can be defined as `SIGNED`, `UNSIGNED` or `ZEROFILL`, for example:

```
TINYINT[(M)] [SIGNED | UNSIGNED | ZEROFILL]
```

If `SIGNED`, or no attribute, is specified, a portion of the numeric type will be reserved for the sign (plus or minus). For example, a `TINYINT SIGNED` can range from -128 to 127.

If `UNSIGNED` is specified, no portion of the numeric type is reserved for the sign, so for integer types range can be larger. For example, a `TINYINT UNSIGNED` can range from 0 to 255. Floating point and fixed-point types also can be `UNSIGNED`, but this only prevents negative values from being stored and doesn't alter the range.

If `ZEROFILL` is specified, the column will be set to `UNSIGNED` and the spaces used by default to pad the field are replaced with zeros. `ZEROFILL` is ignored in expressions or as part of a UNION. `ZEROFILL` is a non-standard MySQL and MariaDB enhancement.

Note that although the preferred syntax indicates that the attributes are exclusive, more than one attribute can be specified.

Only the following combinations are supported:

- `SIGNED`
- `UNSIGNED`
- `ZEROFILL`
- `UNSIGNED ZEROFILL`
- `ZEROFILL UNSIGNED`

The latter two should be replaced with simply `ZEROFILL`, but are still accepted by the parser.

Examples

```
CREATE TABLE zf (
  i1 TINYINT SIGNED,
  i2 TINYINT UNSIGNED,
  i3 TINYINT ZEROFILL
);

INSERT INTO zf VALUES (2,2,2);

SELECT * FROM zf;
+------+------+------+
| i1   | i2   | i3   |
+------+------+------+
|    2 |    2 |  002 |
+------+------+------+
```

Range

When attempting to add a value that is out of the valid range for the numeric type, MariaDB will react depending on the strict SQL_MODE setting.

If strict_mode has been set (the default), MariaDB will return an error.

If strict_mode has not been set, MariaDB will adjust the number to fit in the field, returning a warning.

Examples

With `strict_mode` set:

```
SHOW VARIABLES LIKE 'sql_mode';
+---------------+-----------------------------------------------------------------------------------------------
---+
| Variable_name | Value
|
+---------------+-----------------------------------------------------------------------------------------------
---+
| sql_mode      |
STRICT_TRANS_TABLES,ERROR_FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION |
+---------------+-----------------------------------------------------------------------------------------------
---+

CREATE TABLE ranges (i1 TINYINT, i2 SMALLINT, i3 TINYINT UNSIGNED);

INSERT INTO ranges VALUES (257,257,257);
ERROR 1264 (22003): Out of range value for column 'i1' at row 1

SELECT * FROM ranges;
Empty set (0.10 sec)
```

With `strict_mode` unset:

```
SHOW VARIABLES LIKE 'sql_mode%';
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| sql_mode      |       |
+---------------+-------+

CREATE TABLE ranges (i1 TINYINT, i2 SMALLINT, i3 TINYINT UNSIGNED);

INSERT INTO ranges VALUES (257,257,257);
Query OK, 1 row affected, 2 warnings (0.00 sec)

SHOW WARNINGS;
+---------+------+--------------------------------------------+
| Level   | Code | Message                                    |
+---------+------+--------------------------------------------+
| Warning | 1264 | Out of range value for column 'i1' at row 1 |
| Warning | 1264 | Out of range value for column 'i3' at row 1 |
+---------+------+--------------------------------------------+
2 rows in set (0.00 sec)

SELECT * FROM ranges;
+------+------+------+
| i1   | i2   | i3   |
+------+------+------+
|  127 |  257 |  255 |
+------+------+------+
```

AUTO_INCREMENT

The `AUTO_INCREMENT` attribute can be used to generate a unique identity for new rows. For more details, see auto_increment.

This page is licensed: CC BY-SA / Gnu FDL

BIGINT

Syntax

```
BIGINT[(M)] [SIGNED | UNSIGNED | ZEROFILL]
```

Description

A large integer. The signed range is `-9223372036854775808` to `9223372036854775807`. The unsigned range is `0` to `18446744073709551615`.

If a column has been set to `ZEROFILL`, all values will be prepended by zeros so that the `BIGINT` value contains a number of M digits.

Note: If the `ZEROFILL` attribute has been specified, the column will automatically become `UNSIGNED`.

For more details on the attributes, see Numeric Data Type Overview.

`SERIAL` is an alias for:

```
BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE
```

`INT8` is a synonym for `BIGINT`.

EXAMPLES

With strict_mode set

```
CREATE TABLE bigints (a BIGINT,b BIGINT UNSIGNED,c BIGINT ZEROFILL);

INSERT INTO bigints VALUES (-10,-10,-10);
ERROR 1264 (22003): Out of range value for column 'b' at row 1

INSERT INTO bigints VALUES (-10,10,-10);
ERROR 1264 (22003): Out of range value for column 'c' at row 1

INSERT INTO bigints VALUES (-10,10,10);

INSERT INTO bigints VALUES (9223372036854775808,9223372036854775808,9223372036854775808);
ERROR 1264 (22003): Out of range value for column 'a' at row 1

INSERT INTO bigints VALUES (9223372036854775807,9223372036854775808,9223372036854775808);

SELECT * FROM bigints;
+---------------------+---------------------+----------------------+
| a                   | b                   | c                    |
+---------------------+---------------------+----------------------+
|                 -10 |                  10 | 00000000000000000010 |
| 9223372036854775807 | 9223372036854775808 | 09223372036854775808 |
+---------------------+---------------------+----------------------+
```

SIGNED and UNSIGNED

The `BIGINT` data type may be `SIGNED` (allowing negative values) or `UNSIGNED` (not allowing negative values).

Example of `BIGINT SIGNED` (the default):

```
CREATE TABLE bigint_signed_example (
   description VARCHAR(20),
   example BIGINT SIGNED
);
```

```
INSERT INTO bigint_signed_example VALUES
   ('Zero', 0),
   ('Forty-Two', 42),
   ('Minimum', -9223372036854775808),
   ('Maximum', 9223372036854775807);
```

Example of BIGINT UNSIGNED:

```
CREATE TABLE bigint_unsigned_example (
   description VARCHAR(20),
   example BIGINT UNSIGNED
);
```

```
INSERT INTO bigint_unsigned_example VALUES
   ('Zero', 0),
   ('Forty-Two', 42),
   ('Minimum', 0),
   ('Maximum', 18446744073709551615);
```

Out of Range

A value is considered “out of range” when it is too small or too large to be stored in a data type. When `sql_mode=STRICT_TRANS_TABLES` (the default) is set, an out-of-range value generates an error. If strict mode is not

in effect, the value is rounded to the nearest valid value and a warning is generated (which might be hidden, depending on your warning settings).

An example of non-strict out-of-range behavior:

```
TRUNCATE bigint_signed_example;

-- Disable strict mode or the inserts will fail
SET sql_mode=(SELECT REPLACE(@@sql_mode, 'STRICT_TRANS_TABLES', ''));

INSERT INTO bigint_signed_example VALUES
   ('Underflow', -9223372036854775809),
   ('Overflow', 9223372036854775808);

Warning (Code 1264): Out of range value for column 'example' at row 1
Warning (Code 1264): Out of range value for column 'example' at row 2

SELECT * FROM bigint_signed_example;

+-------------+----------------------+
| description | example              |
+-------------+----------------------+
| Underflow   | -9223372036854775808 |
| Overflow    |  9223372036854775807 |
+-------------+----------------------+

TRUNCATE bigint_unsigned_example;

-- Disable strict mode or the inserts will fail
SET sql_mode=(SELECT REPLACE(@@sql_mode, 'STRICT_TRANS_TABLES', ''));

INSERT INTO bigint_unsigned_example VALUES
   ('Underflow', -1),
   ('Overflow', 18446744073709551616);

Warning (Code 1264): Out of range value for column 'example' at row 1
Warning (Code 1264): Out of range value for column 'example' at row 2

SELECT * FROM bigint_unsigned_example;

+-------------+----------------------+
| description | example              |
+-------------+----------------------+
| Underflow   |                    0 |
| Overflow    | 18446744073709551615 |
+-------------+----------------------+
```

BIGINT ZEROFILL

A special type of `BIGINT UNSIGNED is BIGINT ZEROFILL`, which pads out the values with leading zeros in `SELECT` results. The number of leading zeros are just enough to pad the field out to the length of the type's maximum unsigned value, but the zeros are not included in an expression result or in a `UNION SELECT` column.

Using `BIGINT ZEROFILL` works the same way as `BIGINT UNSIGNED` for most operations except a simple `SELECT`. For example, with the following test table setup:

```
CREATE TABLE bigint_zerofill_example (
   description VARCHAR(20),
   example BIGINT ZEROFILL
);

INSERT INTO bigint_zerofill_example VALUES
   ('Zero', 0),
   ('Forty-Two', 42),
   ('Minimum', 0),
   ('Maximum', 18446744073709551615);

-- Turn off strict mode or the inserts will fail
SET sql_mode=(SELECT REPLACE(@@sql_mode, 'STRICT_TRANS_TABLES', ''));

INSERT INTO bigint_zerofill_example VALUES
   ('Underflow', -1),
   ('Overflow', 18446744073709551616);

Warning (Code 1264): Out of range value for column 'example' at row 1
Warning (Code 1264): Out of range value for column 'example' at row 2
```

The resulting data would look like this:

```
SELECT *, example + 0 FROM bigint_zerofill_example;

+-------------+----------------------+----------------------+
| description | example              | example + 0          |
+-------------+----------------------+----------------------+
| Zero        | 00000000000000000000 |                    0 |
| Forty-Two   | 00000000000000000042 |                   42 |
| Minimum     | 00000000000000000000 |                    0 |
| Maximum     | 18446744073709551615 | 18446744073709551615 |
| Underflow   | 00000000000000000000 |                    0 |
| Overflow    | 18446744073709551615 | 18446744073709551615 |
+-------------+----------------------+----------------------+
```

BIT

Syntax

```
BIT[(M)]
```

Description

A bit-field type. `M` indicates the number of bits per value, from `1` to `64`. The default is `1` if `M` is omitted.

Bit values can be inserted with `b'value'` notation, where `value` is the bit value in 0's and 1's.

Bit fields are automatically zero-padded from the left to the full length of the bit, so for example in a `BIT(4)` field, '10' is equivalent to '0010'.

Bits are returned as binary, so to display them, either add 0, or use a function such as HEX, OCT or BIN to convert them.

Examples

Example of BIT:

```
CREATE TABLE bit_example (
  description VARCHAR(20),
  b1 BIT,
  b4 BIT(4),
  b16 BIT(16)
);
```

```
INSERT INTO bit_example VALUES
  ('Zero', 0, 0, 0),
  ('One', 1, 1, 1),
  ('Two', 0, 2, 2),
  ('Eight', 0, 8, b'1000'),
  ('All on', 1, 15, b'1111111111111111');
SELECT description, b1+0, LPAD(BIN(b4), 4, 0) AS b4, HEX(b16)
  FROM bit_example;

+-------------+------+------+----------+
| description | b1+0 | b4   | HEX(b16) |
+-------------+------+------+----------+
| Zero        |    0 | 0000 | 0        |
| One         |    1 | 0001 | 1        |
| Two         |    0 | 0010 | 2        |
| Eight       |    0 | 1000 | 8        |
| All on      |    1 | 1111 | FFFF     |
+-------------+------+------+----------+
```

With strict_mode set

```
CREATE TABLE b ( b1 BIT(8) );
```

```
INSERT INTO b VALUES (b'11111111');

INSERT INTO b VALUES (b'01010101');

INSERT INTO b VALUES (b'1111111111111');
ERROR 1406 (22001): Data too long for column 'b1' at row 1

SELECT b1+0, HEX(b1), OCT(b1), BIN(b1) FROM b;
+------+---------+---------+----------+
| b1+0 | HEX(b1) | OCT(b1) | BIN(b1)  |
+------+---------+---------+----------+
|  255 | FF      | 377     | 11111111 |
|   85 | 55      | 125     | 1010101  |
+------+---------+---------+----------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

BOOL

Overview

See TINYINT.

EXAMPLES

```
CREATE TABLE bool_example (
  example BOOL
) DEFAULT CHARSET=latin1;
```

```
SHOW CREATE TABLE bool_example\G
```

```
*************************** 1. row ***************************
       Table: bool_example
Create Table: CREATE TABLE `bool_example` (
  `example` tinyint(1) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

This page is: Copyright © 2026 MariaDB. All rights reserved.

BOOLEAN

Syntax

```
BOOL, BOOLEAN
```

Description

These types are synonyms for TINYINT(1). A value of zero is considered false. Non-zero values are considered true.

However, the values `TRUE` and `FALSE` are merely aliases for 1 and 0. See Boolean Literals, as well as the IS operator for testing values against a boolean.

Examples

```
CREATE TABLE boolean_example (
  example BOOLEAN
);
```

```
SHOW CREATE TABLE boolean_example\G
```

```
*************************** 1. row ***************************
       Table: boolean_example
Create Table: CREATE TABLE `boolean_example` (
  `example` tinyint(1) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

```
CREATE TABLE boo (i BOOLEAN);

DESC boo;
+-------+------------+------+-----+---------+-------+
| Field | Type       | Null | Key | Default | Extra |
+-------+------------+------+-----+---------+-------+
| i     | tinyint(1) | YES  |     | NULL    |       |
+-------+------------+------+-----+---------+-------+
```

```
SELECT IF(0, 'true', 'false');
+------------------------+
| IF(0, 'true', 'false') |
+------------------------+
| false                  |
+------------------------+

SELECT IF(1, 'true', 'false');
+------------------------+
| IF(1, 'true', 'false') |
+------------------------+
| true                   |
+------------------------+

SELECT IF(2, 'true', 'false');
+------------------------+
| IF(2, 'true', 'false') |
+------------------------+
| true                   |
+------------------------+
```

`TRUE` and `FALSE` as aliases for 1 and 0:

```
SELECT IF(0 = FALSE, 'true', 'false');

+--------------------------------+
| IF(0 = FALSE, 'true', 'false') |
+--------------------------------+
| true                           |
+--------------------------------+

SELECT IF(1 = TRUE, 'true', 'false');
+-------------------------------+
| IF(1 = TRUE, 'true', 'false') |
+-------------------------------+
| true                          |
+-------------------------------+

SELECT IF(2 = TRUE, 'true', 'false');
+-------------------------------+
| IF(2 = TRUE, 'true', 'false') |
+-------------------------------+
| false                         |
+-------------------------------+

SELECT IF(2 = FALSE, 'true', 'false');
+--------------------------------+
| IF(2 = FALSE, 'true', 'false') |
+--------------------------------+
| false                          |
+--------------------------------+
```

The last two statements display the results shown because 2 is equal to neither 1 nor 0.

DEC, NUMERIC, FIXED

Syntax

```
DEC[(M[,D])] [SIGNED | UNSIGNED | ZEROFILL]

NUMERIC[(M[,D])] [SIGNED | UNSIGNED | ZEROFILL]

FIXED[(M[,D])] [SIGNED | UNSIGNED | ZEROFILL]
```

Description

These types are synonyms for DECIMAL. The `FIXED` synonym is available for compatibility with other database systems.

This page is licensed: GPLv2, originally from fill_help_tables.sql

DEC

See DECIMAL.

EXAMPLES

```
CREATE TABLE dec_example (
  example DEC
);
```

```
SHOW CREATE TABLE dec_example\G
```

```
*************************** 1. row ***************************
       Table: dec_example
Create Table: CREATE TABLE `dec_example` (
  `example` decimal(10,0) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

This page is: Copyright © 2026 MariaDB. All rights reserved.

DECIMAL

Syntax

```
DECIMAL[(M[,D])] [SIGNED | UNSIGNED | ZEROFILL]
```

Description

A packed “exact” fixed-point number. `M` is the total number of digits (the precision), and `D` is the number of digits after the decimal point (the scale).

- The decimal point and (for negative numbers) the “-” sign are not counted in `M`.
- If `D` is `0`, values have no decimal point or fractional part, and on INSERT, the value will be rounded to the nearest `DECIMAL`.
- The maximum number of digits (`M`) for `DECIMAL` is 65.
- The maximum number of supported decimals (`D`) is `30` before MariaDB 10.2.1 and `38` afterwards.
- If `D` is omitted, the default is `0`. If `M` is omitted, the default is `10`.

`UNSIGNED`, if specified, disallows negative values.

`ZEROFILL`, if specified, pads the number with zeros, up to the total number of digits specified by `M`.

All basic calculations (+, -, *, /) with `DECIMAL` columns are done with a precision of 65 digits.

For more details on the attributes, see Numeric Data Type Overview.

`DEC`, `NUMERIC`, and `FIXED` are synonyms, as well as `NUMBER` in Oracle mode.

Examples

```
CREATE TABLE t1 (d DECIMAL UNSIGNED ZEROFILL);

INSERT INTO t1 VALUES (1),(2),(3),(4.0),(5.2),(5.7);
Query OK, 6 rows affected, 2 warnings (0.16 sec)
Records: 6  Duplicates: 0  Warnings: 2

Note (sql 1265): Data truncated for column 'd' at row 5
Note (sql 1265): Data truncated for column 'd' at row 6

SELECT * FROM t1;
+------------+
| d          |
+------------+
| 0000000001 |
| 0000000002 |
| 0000000003 |
| 0000000004 |
| 0000000005 |
| 0000000006 |
+------------+
```

With strict_mode set

```
INSERT INTO t1 VALUES (-7);
ERROR 1264 (22003): Out of range value for column 'd' at row 1
```

SIGNED and UNSIGNED

The `DECIMAL` data type may be `SIGNED` (allowing negative values) or `UNSIGNED` (not allowing negative values).

Example of `DECIMAL SIGNED` (`SIGNED` is the default):

```
CREATE TABLE decimal_signed_example (
  description VARCHAR(20),
  sz10_0 DECIMAL,
  sz6_2 DECIMAL(6,2),
  sz20_19 DECIMAL(20,19) SIGNED
);
```

```
SET @pi = 3.14159265358979323846264338327950;
```

```
INSERT INTO decimal_signed_example VALUES
  ('Pi', @pi, @pi, @pi),
  ('Series', 1234.567890123, 1234.567890123, 1.234567890123),
  ('Negative', -1234.567890123, -1234.567890123, -1.234567890123),
  ('Various', 1234567890, 9999.99, 9.9999999999999999999);
```

```
SELECT * FROM decimal_signed_example;

+-------------+------------+----------+-----------------------+
| description | sz10_0     | sz6_2    | sz20_19               |
+-------------+------------+----------+-----------------------+
| Pi          |          3 |     3.14 |  3.1415926535897932385 |
| Series      |       1235 |  1234.57 |  1.2345678901230000000 |
| Negative    |      -1235 | -1234.57 | -1.2345678901230000000 |
| Various     | 1234567890 |  9999.99 |  9.9999999999999999999 |
+-------------+------------+----------+-----------------------+
```

Example of `DECIMAL UNSIGNED`:

```
CREATE TABLE decimal_unsigned_example (
  description VARCHAR(20),
  sz10_0 DECIMAL UNSIGNED,
  sz6_2 DECIMAL(6,2) UNSIGNED,
  sz20_19 DECIMAL(20,19) UNSIGNED
);
```

```
SET @pi = 3.14159265358979323846264338327950;
```

```
INSERT INTO decimal_unsigned_example VALUES
  ('Pi', @pi, @pi, @pi),
  ('Series', 1234.567890123, 1234.567890123, 1.234567890123),
  ('Various', 1234567890, 9999.99, 9.9999999999999999999);
```

```
SELECT * FROM decimal_unsigned_example;

+-------------+------------+---------+-----------------------+
| description | sz10_0     | sz6_2   | sz20_19               |
+-------------+------------+---------+-----------------------+
| Pi          |          3 |    3.14 | 3.1415926535897932385 |
| Series      |       1235 | 1234.57 | 1.2345678901230000000 |
| Various     | 1234567890 | 9999.99 | 9.9999999999999999999 |
+-------------+------------+---------+-----------------------+
```

Out of Range

A value is considered “out of range” when it is too small or too large to be stored in a data type. The size specified when creating the column is the strict limit for what values can be represented. When `SQL_MODE` is strict (the default), an out-of-range value generates an error, and the operation fails. If strict mode is not in effect, the value is rounded to the nearest valid value, and a warning is generated (which might be hidden, depending on your warning settings).

A value whose significant digits must be rounded to fit only generates a warning note about data truncation, since it is only an out-of-range value if the rounding causes the value to overflow.

```
TRUNCATE decimal_signed_example;

-- Disable strict mode
SET sql_mode=(SELECT REPLACE(@@sql_mode, 'STRICT_TRANS_TABLES', ''));

INSERT INTO decimal_signed_example VALUES
  ('OK', 9999999999.4, NULL, NULL),
  ('Rounded overflow', 9999999999.5, NULL, NULL),
  ('Overflow', 10000000000, NULL, NULL),
  ('OK', -9999999999.4, NULL, NULL),
  ('Rounded underflow', -9999999999.5, NULL, NULL),
  ('Underflow', -10000000000, NULL, NULL),
  ('OK', NULL, 9999.994, NULL),
  ('Rounded overflow', NULL, 9999.995, NULL),
  ('Overflow', NULL, 10000, NULL),
  ('OK', NULL, -9999.994, NULL),
  ('Rounded underflow', NULL, -9999.995, NULL),
  ('Underflow', NULL, -10000, NULL),
  ('OK', NULL, NULL, 9.99999999999999999994),
  ('Rounded overflow', NULL, NULL, 9.99999999999999999995),
  ('Overflow', NULL, NULL, 10),
  ('OK', NULL, NULL, -9.99999999999999999994),
  ('Rounded underflow', NULL, NULL, -9.99999999999999999995),
  ('Underflow', NULL, NULL, -10);
```

```
Note (sql 1265): Data truncated for column 'sz10_0' at row 1
Warning (sql 1264): Out of range value for column 'sz10_0' at row 2
Warning (sql 1264): Out of range value for column 'sz10_0' at row 3

+-------------------+-------------+----------+------------------------+
```

DECIMAL ZEROFILL

A special type of `DECIMAL UNSIGNED` is `DECIMAL ZEROFILL`, which pads out the values with leading zeros in `SELECT` results. The number of leading zeros is just enough to pad the field out to the length of the type's field size (not counting the decimal place), but the zeros are not included in an expression result or in a `UNION SELECT` column.

Using `DECIMAL ZEROFILL` works the same way as `DECIMAL UNSIGNED` for most operations except a simple `SELECT`. For example, with the following test table setup:

```
CREATE TABLE decimal_zerofill_example (
  description VARCHAR(20),
  sz10_0 DECIMAL ZEROFILL,
  sz6_2 DECIMAL(6,2) ZEROFILL,
  sz20_19 DECIMAL(20,19) ZEROFILL
);
```

```
SET @pi = 3.14159265358979323846264338327950;
```

```
INSERT INTO decimal_zerofill_example VALUES
  ('Pi', @pi, @pi, @pi),
  ('Series', 1234.567890123, 1234.567890123, 1.234567890123),
  ('Various', 1234567890, 9999.99, 9.9999999999999999999);
```

```
SELECT * FROM decimal_zerofill_example;

+-------------+------------+---------+------------------------+
| description | sz10_0     | sz6_2   | sz20_19                |
+-------------+------------+---------+------------------------+
| Pi          | 0000000003 | 0003.14 | 3.1415926535897932385 |
| Series      | 0000001235 | 1234.57 | 1.2345678901230000000 |
| Various     | 1234567890 | 9999.99 | 9.9999999999999999999 |
+-------------+------------+---------+------------------------+
```

DOUBLE PRECISION

Syntax

```
DOUBLE PRECISION[(M,D)] [SIGNED | UNSIGNED | ZEROFILL]
REAL[(M,D)] [SIGNED | UNSIGNED | ZEROFILL]
```

Description

`REAL` and `DOUBLE PRECISION` are synonyms for DOUBLE.

Exception: If the `REAL_AS_FLOAT` SQL mode is enabled, `REAL` is a synonym for FLOAT rather than DOUBLE.

EXAMPLES

```
CREATE TABLE double_precision_example (
  example DOUBLE PRECISION
);
```

```
SHOW CREATE TABLE double_precision_example\G
<</code>>

<<sql>>

*************************** 1. row ***************************
       Table: double_precision_example
Create Table: CREATE TABLE `double_precision_example` (
  `example` double DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

DOUBLE

Syntax

```
DOUBLE[(M,D)] [SIGNED | UNSIGNED | ZEROFILL]
DOUBLE PRECISION[(M,D)] [SIGNED | UNSIGNED | ZEROFILL]
REAL[(M,D)] [SIGNED | UNSIGNED | ZEROFILL]
```

Description

A normal-size (double-precision) floating-point number (see FLOAT for a single-precision floating-point number). Allowable values are:

- `-1.7976931348623157E+308` to `-2.2250738585072014E-308`
- `0`
- `2.2250738585072014E-308` to `1.7976931348623157E+308`

These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

`M` is the total number of digits and `D` is the number of digits following the decimal point. If `M` and `D` are omitted, values are stored to the limits allowed by the hardware. A double-precision floating-point number is accurate to approximately 15 decimal places.

`UNSIGNED`, if specified, disallows negative values.

`ZEROFILL`, if specified, pads the number with zeros, up to the total number of digits specified by `M`.

`REAL` and `DOUBLE PRECISION` are synonyms, unless the `REAL_AS_FLOAT` SQL mode is enabled, in which case `REAL` is a synonym for FLOAT rather than `DOUBLE`.

See Floating Point Accuracy for issues when using floating-point numbers.

For more details on the attributes, see Numeric Data Type Overview.

Examples

```
CREATE TABLE t1 (d DOUBLE(5,0) zerofill);

INSERT INTO t1 VALUES (1),(2),(3),(4);

SELECT * FROM t1;
+-------+
| d     |
+-------+
| 00001 |
| 00002 |
| 00003 |
| 00004 |
+-------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

FIXED

Overview

See DECIMAL.

EXAMPLES

```
CREATE TABLE fixed_example (
  example FIXED
);
```

```
SHOW CREATE TABLE fixed_example\G

*************************** 1. row ***************************
       Table: fixed_example
Create Table: CREATE TABLE `fixed_example` (
  `example` decimal(10,0) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

This page is: Copyright © 2026 MariaDB. All rights reserved.

FLOAT

Syntax

```
FLOAT[(M,D)] [SIGNED | UNSIGNED | ZEROFILL]
```

Description

A small (single-precision) floating-point number (see DOUBLE for a regular-size floating point number). Allowable values are:

- -3.402823466E+38 to -1.175494351E-38

- 0
- 1.175494351E-38 to 3.402823466E+38.

These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

M is the total number of digits and D is the number of digits following the decimal point. If M and D are omitted, values are stored to the limits allowed by the hardware. A single-precision floating-point number is accurate to approximately 7 decimal places.

`UNSIGNED`, if specified, disallows negative values.

Using `FLOAT` might give you some unexpected problems because all calculations in MariaDB are done with double precision. See Floating Point Accuracy.

For more details on the attributes, see Numeric Data Type Overview.

EXAMPLES

SIGNED and UNSIGNED

The `FLOAT` data type may be `SIGNED` (allowing negative values) or `UNSIGNED` (not allowing negative values).

Example of `FLOAT SIGNED` (`SIGNED` is the default):

```
CREATE TABLE float_signed_example (
  description VARCHAR(20),
  example FLOAT,
  sz6_2 FLOAT(6,2),
  sz20_19 FLOAT(20,19) SIGNED
);
```

```
SET @pi = 3.14159265358979323846264338327795;

INSERT INTO float_signed_example VALUES
  ('Pi', @pi, @pi, @pi),
  ('Series', 1234.567890123, 1234.567890123, 1.234567890123),
  ('Negative', -1234.567890123, -1234.567890123, -1.234567890123),
  ('Various', 1234567890, 9999.99, 9.9999999999999999);
```

```
SELECT * FROM float_signed_example;

+-------------+------------+----------+------------------------+
| description | example    | sz6_2    | sz20_19                |
+-------------+------------+----------+------------------------+
| Pi          |    3.14159 |     3.14 |  3.1415927410125732000 |
| Series      |    1234.57 |  1234.57 |  1.2345678806304932000 |
| Negative    |   -1234.57 | -1234.57 | -1.2345678806304932000 |
| Various     | 1234570000 |  9999.99 | 10.0000000000000000000 |
+-------------+------------+----------+------------------------+
```

Example of `FLOAT UNSIGNED`:

```
CREATE TABLE float_unsigned_example (
  description VARCHAR(20),
  example FLOAT UNSIGNED,
  sz6_2 FLOAT(6,2) UNSIGNED,
  sz20_19 FLOAT(20,19) UNSIGNED
);
```

```
SET @pi = 3.14159265358979323846264338327795;
```

```
INSERT INTO float_unsigned_example VALUES
  ('Pi', @pi, @pi, @pi),
  ('Series', 1234.567890123, 1234.567890123, 1.234567890123),
  ('Various', 1234567890, 9999.99, 9.9999999999999999);
```

```
SELECT * FROM float_unsigned_example;

+-------------+------------+---------+------------------------+
| description | example    | sz6_2   | sz20_19                |
+-------------+------------+---------+------------------------+
| Pi          |    3.14159 |    3.14 |  3.1415927410125732000 |
| Series      |    1234.57 | 1234.57 |  1.2345678806304932000 |
| Various     | 1234570000 | 9999.99 | 10.0000000000000000000 |
+-------------+------------+---------+------------------------+
```

Out of Range

A value is considered “out of range” when it is too small or too large to be stored in a data type. The size specified when creating the column is the limit for what values can be represented. The limits can also vary based on your hardware and operating system. When `SQL_MODE` is strict (the default) an out-of-range value generates an error and the operation fails. If strict mode is not in effect, the value is rounded to the nearest valid value and a warning is generated (which might be hidden, depending on your warning settings).

A value whose significant digits must be rounded to fit only generates a warning note about data truncation, since it is only an out-of-range value if the rounding causes the value to overflow. A somewhat strange exception happens when the decimal places are 16 digits or larger: at that point the value can round up to be one digit larger than you would expect to be accepted, but only for the next larger power of 10. For instance, a `FLOAT(17,16)` should max out at 9.9999999999999999, but that value rounds up to being equivalent to 10 (and 11 overflows).

```
TRUNCATE float_signed_example;

-- Disable strict mode
SET sql_mode=(SELECT REPLACE(@@sql_mode, 'STRICT_TRANS_TABLES', ''));

INSERT INTO float_signed_example VALUES
  ('OK', 3.402823466e38, NULL, NULL),
  ('Overflow', 4.0e38, NULL, NULL),
  ('OK', -3.402823466e38, NULL, NULL),
  ('Underflow', -4.0e38, NULL, NULL),
  ('OK', NULL, 9999.99, NULL),
  ('Rounded overflow', NULL, 9999.995, NULL),
  ('Overflow', NULL, 10000, NULL),
  ('OK', NULL, -9999.99, NULL),
  ('Rounded underflow', NULL, -9999.995, NULL),
  ('Underflow', NULL, -10000, NULL),
  ('OK', NULL, NULL, 9.9999999999999999),
  ('Rounded OK', NULL, NULL, 9.99999999999999995),
  ('Overflow', NULL, NULL, 11),
  ('OK', NULL, NULL, -9.9999999999999999),
  ('Rounded OK', NULL, NULL, -9.99999999999999995),
  ('Underflow', NULL, NULL, -11);
```

```
Warning (sql 1264): Out of range value for column 'example' at row 2
Warning (sql 1264): Out of range value for column 'example' at row 4
Warning (sql 1264): Out of range value for column 'sz6_2' at row 6
Warning (sql 1264): Out of range value for column 'sz6_2' at row 7
Warning (sql 1264): Out of range value for column 'sz6_2' at row 9

| Rounded OK        |        NULL |     NULL | -10.0000000000000000000 |
| Underflow         |        NULL |     NULL | -10.0000000000000000000 |
+-------------------+-------------+----------+-------------------------+
```

```
TRUNCATE float_unsigned_example;

-- Disable strict mode
SET sql_mode=(SELECT REPLACE(@@sql_mode, 'STRICT_TRANS_TABLES', ''));

INSERT INTO float_unsigned_example VALUES
  ('OK', 3.402823466e38, NULL, NULL),
  ('Overflow', 4.0e38, NULL, NULL),
  ('Underflow', -1, NULL, NULL);
```

```
Warning (sql 1264): Out of range value for column 'example' at row 2
Warning (sql 1264): Out of range value for column 'example' at row 3
```

```
SELECT * FROM float_unsigned_example;

+-------------+------------+-------+---------+
| description | example    | sz6_2 | sz20_19 |
+-------------+------------+-------+---------+
| OK          | 3.40282e38 |  NULL |    NULL |
| Overflow    | 3.40282e38 |  NULL |    NULL |
| Underflow   |          0 |  NULL |    NULL |
+-------------+------------+-------+---------+
```

FLOAT ZEROFILL

A special type of `FLOAT UNSIGNED` is `FLOAT ZEROFILL`, which pads out the values with leading zeros in `SELECT` results. The number of leading zeros are just enough to pad the field out to the length of the type's field size (counting the decimal point), but the zeros are not included in an expression result or in a `UNION SELECT` column.

Using `FLOAT ZEROFILL` works the same way as `FLOAT UNSIGNED` for most operations except a simple `SELECT`. For example, with the following test table setup:

```
CREATE TABLE float_zerofill_example (
  description VARCHAR(20),
  example FLOAT ZEROFILL,
  sz6_2 FLOAT(6,2) ZEROFILL,
  sz20_19 FLOAT(20,19) ZEROFILL
);
```

```
SET @pi = 3.14159265358979323846264338327795;
```

```
INSERT INTO float_zerofill_example VALUES
  ('Pi', @pi, @pi, @pi),
  ('Series', 1234.567890123, 1234.567890123, 1.234567890123),
  ('Various', 1234567890, 9999.99, 9.9999999999999999999);
```

```
SELECT * FROM float_zerofill_example;

+-------------+--------------+---------+------------------------+
| description | example      | sz6_2   | sz20_19                |
+-------------+--------------+---------+------------------------+
| Pi          | 000003.14159 |  003.14 |  3.1415927410125732000 |
| Series      | 000001234.57 | 1234.57 |  1.2345678806304932000 |
| Various     | 001234570000 | 9999.99 | 10.0000000000000000000 |
+-------------+--------------+---------+------------------------+
```

FLOAT4

Overview

See FLOAT.

EXAMPLES

```
CREATE TABLE float4_example (
  example FLOAT4
);
```

```
SHOW CREATE TABLE float4_example\G
```

```
*************************** 1. row ***************************
       Table: float4_example
Create Table: CREATE TABLE `float4_example` (
  `example` float DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

This page is: Copyright © 2026 MariaDB. All rights reserved.

FLOAT8

Overview

See DOUBLE.

EXAMPLES

```
CREATE TABLE float8_example (
  example FLOAT8
);
```

```
SHOW CREATE TABLE float8_example\G

*************************** 1. row ***************************
       Table: float8_example
Create Table: CREATE TABLE `float8_example` (
  `example` double DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

This page is: Copyright © 2026 MariaDB. All rights reserved.

Floating-point Accuracy

Due to their nature, not all floating-point numbers can be stored with exact precision. Hardware architecture, the CPU or even the compiler version and optimization level may affect the precision.

If you are comparing DOUBLEs or FLOATs with numeric decimals, it is not safe to use the equality operator.

Sometimes, changing a floating-point number from single-precision (FLOAT) to double-precision (DOUBLE) will fix the problem.

Example

In the following query, f1, f2 and f3 have seemingly identical values across each row, but due to floating point accuracy, the results may be unexpected.

```
CREATE TABLE fpn (id INT, f1 FLOAT, f2 DOUBLE, f3 DECIMAL (10,3));
INSERT INTO fpn VALUES (1,2,2,2),(2,0.1,0.1,0.1);

SELECT * FROM fpn WHERE f1*f1 = f2*f2;
+------+------+------+-------+
| id   | f1   | f2   | f3    |
+------+------+------+-------+
|    1 |    2 |    2 | 2.000 |
+------+------+------+-------+
```

The reason why only one instead of two rows was returned becomes clear when we see how the floating point squares were evaluated.

```
SELECT f1*f1, f2*f2, f3*f3 FROM fpn;
+----------------------+----------------------+----------+
| f1*f1                | f2*f2                | f3*f3    |
+----------------------+----------------------+----------+
|                    4 |                    4 | 4.000000 |
| 0.010000000298023226 | 0.010000000000000002 | 0.010000 |
+----------------------+----------------------+----------+
```

This page is licensed: CC BY-SA / Gnu FDL

INT

Syntax

```
INT[(M)] [SIGNED | UNSIGNED | ZEROFILL]
INTEGER[(M)] [SIGNED | UNSIGNED | ZEROFILL]
```

Description

A normal-size integer. When marked `UNSIGNED`, it ranges from 0 to 4294967295, otherwise its range is -2147483648 to 2147483647 (`SIGNED` is the default). If a column has been set to `ZEROFILL`, all values will be prepended by zeros so that the `INT` value contains a number of M digits. `INTEGER` is a synonym for `INT`.

> **Note:**
>
> **Note:** If the `ZEROFILL` attribute has been specified, the column will automatically become `UNSIGNED`.

`INT4` is a synonym for `INT`.

For details on the attributes, see Numeric Data Type Overview.

Examples

With strict_mode set

```
CREATE TABLE ints (a INT,b INT UNSIGNED,c INT ZEROFILL);
```

```
INSERT INTO ints VALUES (-10,-10,-10);
ERROR 1264 (22003): Out of range value for column 'b' at row 1

INSERT INTO ints VALUES (-10,10,-10);
ERROR 1264 (22003): Out of range value for column 'c' at row 1

INSERT INTO ints VALUES (-10,10,10);

INSERT INTO ints VALUES (2147483648,2147483648,2147483648);
ERROR 1264 (22003): Out of range value for column 'a' at row 1

INSERT INTO ints VALUES (2147483647,2147483648,2147483648);

SELECT * FROM ints;
+------------+------------+------------+
| a          | b          | c          |
+------------+------------+------------+
|        -10 |         10 | 0000000010 |
| 2147483647 | 2147483648 | 2147483648 |
+------------+------------+------------+
```

SIGNED and UNSIGNED

The `INT` data type may be `SIGNED` (allowing negative values) or `UNSIGNED` (not allowing negative values).

Example of `INT SIGNED` (the default):

```
CREATE TABLE int_signed_example (
   description VARCHAR(20),
   example INT SIGNED
);
```

```
INSERT INTO int_signed_example VALUES
   ('Zero', 0),
   ('Forty-Two', 42),
   ('Minimum', -2147483648),
   ('Maximum', 2147483647);
```

Example of INT UNSIGNED:

```
CREATE TABLE int_unsigned_example (
   description VARCHAR(20),
   example INT UNSIGNED
);
```

```
INSERT INTO int_unsigned_example VALUES
   ('Zero', 0),
   ('Forty-Two', 42),
   ('Minimum', 0),
   ('Maximum', 4294967295);
```

Out-of-Range

A value is considered “out-of-range” when it is too small or too large to be stored in a data type. When sql_mode=`STRICT_TRANS_TABLES` (the default) is set, an out-of-range value generates an error. If strict mode is not in effect, the value is rounded to the nearest valid value and a warning is generated (which might be hidden, depending on your warning settings).

An example of non-strict out-of-range behavior:

```
TRUNCATE int_signed_example;

-- Disable strict mode or the inserts will fail
SET sql_mode=(SELECT REPLACE(@@sql_mode, 'STRICT_TRANS_TABLES', ''));

INSERT INTO int_signed_example VALUES
   ('Underflow', -2147483649),
   ('Overflow', 2147483648);
```

```
Warning (sql 1264): Out of range value for column 'example' at row 1
Warning (sql 1264): Out of range value for column 'example' at row 2
```

```
SELECT * FROM int_signed_example;

+-------------+-------------+
| description | example     |
+-------------+-------------+
| Underflow   | -2147483648 |
| Overflow    |  2147483647 |
+-------------+-------------+
```

```
TRUNCATE int_unsigned_example;

-- Disable strict mode or the inserts will fail
SET sql_mode=(SELECT REPLACE(@@sql_mode, 'STRICT_TRANS_TABLES', ''));

INSERT INTO int_unsigned_example VALUES
   ('Underflow', -1),
   ('Overflow', 4294967296);
```

```
Warning (sql 1264): Out of range value for column 'example' at row 1
Warning (sql 1264): Out of range value for column 'example' at row 2
```

```
SELECT * FROM int_unsigned_example;

+-------------+------------+
| description | example    |
+-------------+------------+
| Underflow   |          0 |
| Overflow    | 4294967295 |
+-------------+------------+
```

INT ZEROFILL

A special type of `INT UNSIGNED` is `INT ZEROFILL`, which pads out the values with leading zeros in `SELECT` results. The number of leading zeros are just enough to pad the field out to the length of the type's maximum unsigned value, but the zeros are not included in an expression result or in a `UNION SELECT` column.

Using `INT ZEROFILL` works the same way as `INT UNSIGNED` for most operations except a simple `SELECT`. For example, with the following test table setup:

```
CREATE TABLE int_zerofill_example (
   description VARCHAR(20),
   example INT ZEROFILL
);
```

```
INSERT INTO int_zerofill_example VALUES
   ('Zero', 0),
   ('Forty-Two', 42),
   ('Minimum', 0),
   ('Maximum', 4294967295);

-- Turn off strict mode or the inserts will fail
SET sql_mode=(SELECT REPLACE(@@sql_mode, 'STRICT_TRANS_TABLES', ''));

INSERT INTO int_zerofill_example VALUES
   ('Underflow', -1),
   ('Overflow', 4294967296);
```

```
Warning (sql 1264): Out of range value for column 'example' at row 1
Warning (sql 1264): Out of range value for column 'example' at row 2
```

The resulting data would look like this:

```
SELECT *, example + 0 FROM int_zerofill_example;

+-------------+------------+-------------+
| description | example    | example + 0 |
+-------------+------------+-------------+
| Zero        | 0000000000 |           0 |
| Forty-Two   | 0000000042 |          42 |
| Minimum     | 0000000000 |           0 |
| Maximum     | 4294967295 |  4294967295 |
| Underflow   | 0000000000 |           0 |
| Overflow    | 4294967295 |  4294967295 |
+-------------+------------+-------------+
```

INT1

`INT1` is a synonym for TINYINT.

```
CREATE TABLE t1 (x INT1);

DESC t1;
+-------+------------+------+-----+---------+-------+
| Field | Type       | Null | Key | Default | Extra |
+-------+------------+------+-----+---------+-------+
| x     | tinyint(4) | YES  |     | NULL    |       |
+-------+------------+------+-----+---------+-------+
```

EXAMPLES

```
CREATE TABLE int1_example (
  example INT1
);
```

```
SHOW CREATE TABLE int1_example\G
```

```
*************************** 1. row ***************************
       Table: int1_example
Create Table: CREATE TABLE `int1_example` (
  `example` tinyint(4) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

This page is licensed: CC BY-SA / Gnu FDL

INT2

`INT2` is a synonym for SMALLINT.

```
CREATE TABLE t1 (x INT2);

DESC t1;
+-------+-------------+------+-----+---------+-------+
| Field | Type        | Null | Key | Default | Extra |
+-------+-------------+------+-----+---------+-------+
| x     | smallint(6) | YES  |     | NULL    |       |
+-------+-------------+------+-----+---------+-------+
```

EXAMPLES

```
CREATE TABLE int2_example (
  example INT2
);
```

```
SHOW CREATE TABLE int2_example\G

*************************** 1. row ***************************
       Table: int2_example
Create Table: CREATE TABLE `int2_example` (
  `example` smallint(6) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

This page is licensed: CC BY-SA / Gnu FDL

INT3

`INT3` is a synonym for MEDIUMINT.

```
CREATE TABLE t1 (x INT3);

DESC t1;
+-------+--------------+------+-----+---------+-------+
| Field | Type         | Null | Key | Default | Extra |
+-------+--------------+------+-----+---------+-------+
| x     | mediumint(9) | YES  |     | NULL    |       |
+-------+--------------+------+-----+---------+-------+
```

EXAMPLES

```
CREATE TABLE int3_example (
  example INT3
);
```

```
SHOW CREATE TABLE int3_example\G

*************************** 1. row ***************************
       Table: int3_example
Create Table: CREATE TABLE `int3_example` (
  `example` mediumint(9) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

This page is licensed: CC BY-SA / Gnu FDL

INT4

`INT4` is a synonym for INT.

```
CREATE TABLE t1 (x INT4);

DESC t1;
+-------+---------+------+-----+---------+-------+
| Field | Type    | Null | Key | Default | Extra |
+-------+---------+------+-----+---------+-------+
| x     | int(11) | YES  |     | NULL    |       |
+-------+---------+------+-----+---------+-------+
```

EXAMPLES

```
CREATE TABLE int4_example (
  example INT4
);
```

```
SHOW CREATE TABLE int4_example\G

*************************** 1. row ***************************
       Table: int4_example
Create Table: CREATE TABLE `int4_example` (
  `example` int(11) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

This page is licensed: CC BY-SA / Gnu FDL

INT8

`INT8` is a synonym for BIGINT.

```
CREATE TABLE t1 (x INT8);

DESC t1;
+-------+------------+------+-----+---------+-------+
| Field | Type       | Null | Key | Default | Extra |
+-------+------------+------+-----+---------+-------+
| x     | bigint(20) | YES  |     | NULL    |       |
+-------+------------+------+-----+---------+-------+
```

EXAMPLES

```
CREATE TABLE int8_example (
  example INT8
);
```

```
SHOW CREATE TABLE int8_example\G

*************************** 1. row ***************************
       Table: int8_example
Create Table: CREATE TABLE `int8_example` (
  `example` bigint(20) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

This page is licensed: CC BY-SA / Gnu FDL

INTEGER

Syntax

```
INTEGER[(M)] [SIGNED | UNSIGNED | ZEROFILL]
```

Description

This type is a synonym for INT.

EXAMPLES

```
CREATE TABLE integer_example (
  example INTEGER
);
```

```
SHOW CREATE TABLE integer_example\G

*************************** 1. row ***************************
       Table: integer_example
Create Table: CREATE TABLE `integer_example` (
  `example` int(11) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

MEDIUMINT

Syntax

```
MEDIUMINT[(M)] [SIGNED | UNSIGNED | ZEROFILL]
```

Description

A medium-sized integer. The signed range is -8388608 to 8388607. The unsigned range is 0 to 16777215.

`ZEROFILL` pads the integer with zeroes and assumes `UNSIGNED` (even if `UNSIGNED` is not specified).

`INT3` is a synonym for `MEDIUMINT`.

For details on the attributes, see Numeric Data Type Overview.

Examples

With strict_mode set

```
CREATE TABLE mediumints (a MEDIUMINT,b MEDIUMINT UNSIGNED,c MEDIUMINT ZEROFILL);

DESCRIBE mediumints;
+-------+--------------------------------+------+-----+---------+-------+
| Field | Type                           | Null | Key | Default | Extra |
+-------+--------------------------------+------+-----+---------+-------+
| a     | mediumint(9)                   | YES  |     | NULL    |       |
| b     | mediumint(8) unsigned          | YES  |     | NULL    |       |
| c     | mediumint(8) unsigned zerofill | YES  |     | NULL    |       |
+-------+--------------------------------+------+-----+---------+-------+
```

```
INSERT INTO mediumints VALUES (-10,-10,-10);
ERROR 1264 (22003): Out of range value for column 'b' at row 1

INSERT INTO mediumints VALUES (-10,10,-10);
ERROR 1264 (22003): Out of range value for column 'c' at row 1

INSERT INTO mediumints VALUES (-10,10,10);

INSERT INTO mediumints VALUES (8388608,8388608,8388608);
ERROR 1264 (22003): Out of range value for column 'a' at row 1

INSERT INTO mediumints VALUES (8388607,8388608,8388608);

SELECT * FROM mediumints;
+---------+---------+----------+
| a       | b       | c        |
+---------+---------+----------+
|     -10 |      10 | 00000010 |
| 8388607 | 8388608 | 08388608 |
+---------+---------+----------+
```

SIGNED and UNSIGNED

The `MEDIUMINT` data type may be `SIGNED` (allowing negative values) or `UNSIGNED` (not allowing negative values).

Example of `MEDIUMINT SIGNED` (the default):

```
CREATE TABLE mediumint_signed_example (
   description VARCHAR(20),
   example MEDIUMINT SIGNED
);
```

```
INSERT INTO mediumint_signed_example VALUES
   ('Zero', 0),
   ('Forty-Two', 42),
   ('Minimum', -8388608),
   ('Maximum', 8388607);
```

Example of `MEDIUMINT UNSIGNED`:

```
CREATE TABLE mediumint_unsigned_example (
   description VARCHAR(20),
   example MEDIUMINT UNSIGNED
);
```

```
INSERT INTO mediumint_unsigned_example VALUES
   ('Zero', 0),
   ('Forty-Two', 42),
   ('Minimum', 0),
   ('Maximum', 16777215);
```

Out of Range

A value is considered “out of range” when it is too small or too large to be stored in a data type. When `sql_mode=STRICT_TRANS_TABLES` (the default) is set, an out-of-range value generates an error. If strict mode is not in effect, the value is rounded to the nearest valid value and a warning is generated (which might be hidden, depending on your warning settings).

An example of non-strict out-of-range behavior:

```
TRUNCATE mediumint_signed_example;
```

```
-- Disable strict mode or the inserts will fail
SET sql_mode=(SELECT REPLACE(@@sql_mode, 'STRICT_TRANS_TABLES', ''));
```

```
INSERT INTO mediumint_signed_example VALUES
   ('Underflow', -8388609),
   ('Overflow', 8388608);
```

```
Warning (sql 1264): Out of range value for column 'example' at row 1
Warning (sql 1264): Out of range value for column 'example' at row 2
```

```
SELECT * FROM mediumint_signed_example;
```

```
+-------------+----------+
| description | example  |
+-------------+----------+
| Underflow   | -8388608 |
| Overflow    |  8388607 |
+-------------+----------+
```

```
TRUNCATE mediumint_unsigned_example;
```

```
-- Disable strict mode or the inserts will fail
SET sql_mode=(SELECT REPLACE(@@sql_mode, 'STRICT_TRANS_TABLES', ''));
```

```
INSERT INTO mediumint_unsigned_example VALUES
   ('Underflow', -1),
   ('Overflow', 16777216);
```

```
Warning (sql 1264): Out of range value for column 'example' at row 1
Warning (sql 1264): Out of range value for column 'example' at row 2
```

```
SELECT * FROM mediumint_unsigned_example;
```

```
+-------------+----------+
| description | example  |
+-------------+----------+
| Underflow   |        0 |
| Overflow    | 16777215 |
+-------------+----------+
```

MEDIUMINT ZEROFILL

A special type of `MEDIUMINT UNSIGNED` is `MEDIUMINT ZEROFILL`, which pads out the values with leading zeros in `SELECT` results. The number of leading zeros are just enough to pad the field out to the length of the type's maximum unsigned value, but the zeros are not included in an expression result or in a `UNION SELECT` column.

Using `MEDIUMINT ZEROFILL` works the same way as `MEDIUMINT UNSIGNED` for most operations except a simple `SELECT`. For example, with the following test table setup:

```
CREATE TABLE mediumint_zerofill_example (
   description VARCHAR(20),
   example MEDIUMINT ZEROFILL
);
```

```
INSERT INTO mediumint_zerofill_example VALUES
   ('Zero', 0),
   ('Forty-Two', 42),
   ('Minimum', 0),
   ('Maximum', 16777215);
```

```
-- Turn off strict mode or the inserts will fail
SET sql_mode=(SELECT REPLACE(@@sql_mode, 'STRICT_TRANS_TABLES', ''));
```

```
INSERT INTO mediumint_zerofill_example VALUES
   ('Underflow', -1),
   ('Overflow', 16777216);
```

```
Warning (sql 1264): Out of range value for column 'example' at row 1
Warning (sql 1264): Out of range value for column 'example' at row 2
```

The resulting data would look like this:

```
SELECT *, example + 0 FROM mediumint_zerofill_example;
```

```
+-------------+----------+-------------+
| description | example  | example + 0 |
+-------------+----------+-------------+
| Zero        | 00000000 |           0 |
| Forty-Two   | 00000042 |          42 |
| Minimum     | 00000000 |           0 |
| Maximum     | 16777215 |    16777215 |
| Underflow   | 00000000 |           0 |
| Overflow    | 16777215 |    16777215 |
+-------------+----------+-------------+
```

MIDDLEINT

Overview

See MEDIUMINT.

EXAMPLES

```
CREATE TABLE middleint_example (
  example MIDDLEINT
);
```

```
SHOW CREATE TABLE middleint_example\G
```

```
*************************** 1. row ***************************
       Table: middleint_example
Create Table: CREATE TABLE `middleint_example` (
  `example` mediumint(9) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

This page is: Copyright © 2026 MariaDB. All rights reserved.

NUMBER

```
NUMBER[(M[,D])] [SIGNED | UNSIGNED | ZEROFILL]
```

In Oracle mode, `NUMBER` is a synonym for DECIMAL.

EXAMPLES

Number_Example

```
SET sql_mode='oracle';
```

```
CREATE TABLE number_example (
  example NUMBER
);
```

```
SHOW CREATE TABLE number_example\G
```

```
*************************** 1. row ***************************
       Table: number_example
Create Table: CREATE TABLE "number_example" (
  "example" double DEFAULT NULL
)
```

This page is licensed: CC BY-SA / Gnu FDL

NUMERIC

Overview

See DECIMAL.

EXAMPLES

```
CREATE TABLE numeric_example (
  example NUMERIC
);
```

```
SHOW CREATE TABLE numeric_example\G
```

```
*************************** 1. row ***************************
       Table: numeric_example
Create Table: CREATE TABLE `numeric_example` (
  `example` decimal(10,0) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

This page is: Copyright © 2026 MariaDB. All rights reserved.

REAL

Overview

See DOUBLE.

EXAMPLES

```
CREATE TABLE real_example (
  example REAL
);
```

```
SHOW CREATE TABLE real_example\G
```

```
*************************** 1. row ***************************
       Table: real_example
Create Table: CREATE TABLE `real_example` (
  `example` double DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

This page is: Copyright © 2026 MariaDB. All rights reserved.

SMALLINT

Syntax

```
SMALLINT[(M)] [SIGNED | UNSIGNED | ZEROFILL]
```

Description

A small integer. The signed range is -32768 to 32767. The unsigned range is 0 to 65535.

If a column has been set to `ZEROFILL`, all values will be prepended by zeros so that the `SMALLINT` value contains a number of M digits.

Note:

If the `ZEROFILL` attribute has been specified, the column will automatically become `UNSIGNED`.

`INT2` is a synonym for `SMALLINT`.

For more details on the attributes, see Numeric Data Type Overview.

Examples

With strict_mode set

```
CREATE TABLE smallints (a SMALLINT,b SMALLINT UNSIGNED,c SMALLINT ZEROFILL);
```

```
INSERT INTO smallints VALUES (-10,-10,-10);
ERROR 1264 (22003): Out of range value for column 'b' at row 1

INSERT INTO smallints VALUES (-10,10,-10);
ERROR 1264 (22003): Out of range value for column 'c' at row 1

INSERT INTO smallints VALUES (-10,10,10);

INSERT INTO smallints VALUES (32768,32768,32768);
ERROR 1264 (22003): Out of range value for column 'a' at row 1

INSERT INTO smallints VALUES (32767,32768,32768);

SELECT * FROM smallints;
+-------+-------+-------+
| a     | b     | c     |
+-------+-------+-------+
|   -10 |    10 | 00010 |
| 32767 | 32768 | 32768 |
+-------+-------+-------+
```

SIGNED and UNSIGNED

The `SMALLINT` data type may be `SIGNED` (allowing negative values) or `UNSIGNED` (not allowing negative values).

Example of `SMALLINT SIGNED` (the default):

```
CREATE TABLE smallint_signed_example (
   description VARCHAR(20),
   example SMALLINT SIGNED
);
```

```
INSERT INTO smallint_signed_example VALUES
   ('Zero', 0),
   ('Forty-Two', 42),
   ('Minimum', -32768),
   ('Maximum', 32767);
```

Example of SMALLINT UNSIGNED:

```
CREATE TABLE smallint_unsigned_example (
   description VARCHAR(20),
   example SMALLINT UNSIGNED
);
```

```
INSERT INTO smallint_unsigned_example VALUES
   ('Zero', 0),
   ('Forty-Two', 42),
   ('Minimum', 0),
   ('Maximum', 65535);
```

Out of Range

A value is considered “out of range” when it is too small or too large to be stored in a data type. When `sql_mode=STRICT_TRANS_TABLES` (the default) is set, an out-of-range value generates an error. If strict mode is not

in effect, the value is rounded to the nearest valid value and a warning is generated (which might be hidden, depending on your warning settings).

An example of non-strict out-of-range behavior:

```
TRUNCATE smallint_signed_example;

-- Disable strict mode or the inserts will fail
SET sql_mode=(SELECT REPLACE(@@sql_mode, 'STRICT_TRANS_TABLES', ''));

INSERT INTO smallint_signed_example VALUES
   ('Underflow', -32769),
   ('Overflow', 32768);
```

```
Warning (Code 1264): Out of range value for column 'example' at row 1
Warning (Code 1264): Out of range value for column 'example' at row 2
```

```
SELECT * FROM smallint_signed_example;

+-------------+---------+
| description | example |
+-------------+---------+
| Underflow   |  -32768 |
| Overflow    |   32767 |
+-------------+---------+
```

```
TRUNCATE smallint_unsigned_example;

-- Disable strict mode or the inserts will fail
SET sql_mode=(SELECT REPLACE(@@sql_mode, 'STRICT_TRANS_TABLES', ''));

INSERT INTO smallint_unsigned_example VALUES
   ('Underflow', -1),
   ('Overflow', 65536);
```

```
Warning (Code 1264): Out of range value for column 'example' at row 1
Warning (Code 1264): Out of range value for column 'example' at row 2
```

```
SELECT * FROM smallint_unsigned_example;
```

```
+-------------+---------+
| description | example |
+-------------+---------+
| Underflow   |       0 |
| Overflow    |   65535 |
+-------------+---------+
```

SMALLINT ZEROFILL

A special type of `SMALLINT UNSIGNED` is `SMALLINT ZEROFILL`, which pads out the values with leading zeros in `SELECT` results. The number of leading zeros are just enough to pad the field out to the length of the type's maximum unsigned value, but the zeros are not included in an expression result or in a `UNION SELECT` column.

Using `SMALLINT ZEROFILL` works the same way as `SMALLINT UNSIGNED` for most operations except a simple `SELECT`. For example, with the following test table setup:

```
CREATE TABLE smallint_zerofill_example (
   description VARCHAR(20),
   example SMALLINT ZEROFILL
);
```

```
INSERT INTO smallint_zerofill_example VALUES
   ('Zero', 0),
   ('Forty-Two', 42),
   ('Minimum', 0),
   ('Maximum', 65535);

-- Turn off strict mode or the inserts will fail
SET sql_mode=(SELECT REPLACE(@@sql_mode, 'STRICT_TRANS_TABLES', ''));

INSERT INTO smallint_zerofill_example VALUES
   ('Underflow', -1),
   ('Overflow', 65536);
```

```
Warning (Code 1264): Out of range value for column 'example' at row 1
Warning (Code 1264): Out of range value for column 'example' at row 2
```

The resulting data would look like this:

```
SELECT *, example + 0 FROM smallint_zerofill_example;
```

```
+-------------+---------+-------------+
| description | example | example + 0 |
+-------------+---------+-------------+
| Zero        |   00000 |           0 |
| Forty-Two   |   00042 |          42 |
| Minimum     |   00000 |           0 |
| Maximum     |   65535 |       65535 |
| Underflow   |   00000 |           0 |
| Overflow    |   65535 |       65535 |
+-------------+---------+-------------+
```

TINYINT

Syntax

```
TINYINT[(M)] [SIGNED | UNSIGNED | ZEROFILL]
```

Description

A very small integer. The signed range is -128 to 127. The unsigned range is 0 to 255. For details on the attributes, see Numeric Data Type Overview.

INT1, BOOL, and BOOLEAN are synonyms for `TINYINT`.

Examples

```
CREATE TABLE tinyints (a TINYINT,b TINYINT UNSIGNED,c TINYINT ZEROFILL);
```

With strict_mode set

```
INSERT INTO tinyints VALUES (-10,-10,-10);
ERROR 1264 (22003): Out of range value for column 'b' at row 1

INSERT INTO tinyints VALUES (-10,10,-10);
ERROR 1264 (22003): Out of range value for column 'c' at row 1

INSERT INTO tinyints VALUES (-10,10,10);

SELECT * FROM tinyints;
+------+------+------+
| a    | b    | c    |
+------+------+------+
|  -10 |   10 |  010 |
+------+------+------+

INSERT INTO tinyints VALUES (128,128,128);
ERROR 1264 (22003): Out of range value for column 'a' at row 1

INSERT INTO tinyints VALUES (127,128,128);

SELECT * FROM tinyints;
+------+------+------+
| a    | b    | c    |
+------+------+------+
|  -10 |   10 |  010 |
|  127 |  128 |  128 |
+------+------+------+
```

SIGNED and UNSIGNED

The `TINYINT` data type may be `SIGNED` (allowing negative values) or `UNSIGNED` (not allowing negative values).

Example of `TINYINT SIGNED` (the default):

```
CREATE TABLE tinyint_signed_example (
   description VARCHAR(20),
   example TINYINT SIGNED
);
```

```
INSERT INTO tinyint_signed_example VALUES
   ('Zero', 0),
   ('Forty-Two', 42),
   ('Minimum', -128),
   ('Maximum', 127);
```

Example of `TINYINT UNSIGNED`:

```
CREATE TABLE tinyint_unsigned_example (
   description VARCHAR(20),
   example TINYINT UNSIGNED
);
```

```
INSERT INTO tinyint_unsigned_example VALUES
   ('Zero', 0),
   ('Forty-Two', 42),
   ('Minimum', 0),
   ('Maximum', 255);
```

Out of Range

A value is considered “out of range” when it is too small or too large to be stored in a data type. When `sql_mode=STRICT_TRANS_TABLES` (the default) is set, an out-of-range value generates an error. If strict mode is not in effect, the value is rounded to the nearest valid value and a warning is generated (which might be hidden, depending on your warning settings).

An example of non-strict out-of-range behavior:

```
TRUNCATE tinyint_signed_example;

-- Disable strict mode or the inserts will fail
SET sql_mode=(SELECT REPLACE(@@sql_mode, 'STRICT_TRANS_TABLES', ''));

INSERT INTO tinyint_signed_example VALUES
   ('Underflow', -129),
   ('Overflow', 128);
```

```
Warning (sql 1264): Out of range value for column 'example' at row 1
Warning (sql 1264): Out of range value for column 'example' at row 2
```

```
SELECT * FROM tinyint_signed_example;
```

```
+-------------+---------+
| description | example |
+-------------+---------+
| Underflow   |    -128 |
| Overflow    |     127 |
+-------------+---------+
```

```
TRUNCATE tinyint_unsigned_example;

-- Disable strict mode or the inserts will fail
SET sql_mode=(SELECT REPLACE(@@sql_mode, 'STRICT_TRANS_TABLES', ''));

INSERT INTO tinyint_unsigned_example VALUES
   ('Underflow', -1),
   ('Overflow', 256);
```

```
Warning (sql 1264): Out of range value for column 'example' at row 1
Warning (sql 1264): Out of range value for column 'example' at row 2
```

```
SELECT * FROM tinyint_unsigned_example;
```

```
+-------------+---------+
| description | example |
+-------------+---------+
| Underflow   |       0 |
| Overflow    |     255 |
+-------------+---------+
```

TINYINT ZEROFILL

A special type of `TINYINT UNSIGNED` is `TINYINT ZEROFILL`, which pads out the values with leading zeros in SELECT results. The number of leading zeros are just enough to pad the field out to the length of the type’s maximum unsigned value, but the zeros are not included in an expression result or in a UNION `SELECT` column.

Using `TINYINT ZEROFILL` works the same way as `TINYINT UNSIGNED` for most operations except a simple `SELECT`. For example, with the following test table setup:

```
CREATE TABLE tinyint_zerofill_example (
   description VARCHAR(20),
   example TINYINT ZEROFILL
);
INSERT INTO tinyint_zerofill_example VALUES
   ('Zero', 0),
   ('Forty-Two', 42),
   ('Minimum', 0),
   ('Maximum', 255);
```

```
-- Turn off strict mode or the inserts will fail
SET sql_mode=(SELECT REPLACE(@@sql_mode, 'STRICT_TRANS_TABLES', ''));
```

```
INSERT INTO tinyint_zerofill_example VALUES
   ('Underflow', -1),
   ('Overflow', 256);
```

```
Warning (sql 1264): Out of range value for column 'example' at row 1
Warning (sql 1264): Out of range value for column 'example' at row 2
```

The resulting data would look like this:

```
SELECT *, example + 0 FROM tinyint_zerofill_example;
```

```
+-------------+---------+-------------+
| description | example | example + 0 |
+-------------+---------+-------------+
| Zero        |     000 |           0 |
| Forty-Two   |     042 |          42 |
| Minimum     |     000 |           0 |
| Maximum     |     255 |         255 |
| Underflow   |     000 |           0 |
| Overflow    |     255 |         255 |
+-------------+---------+-------------+

Date and Time Data Types

See DATE.

Complete DATE type reference: YYYY-MM-DD format, YYMMDD input literals, date range 1000-01-01 to 9999-12-31, and zero-date SQL_MODE handling.

See DATETIME.

Complete DATETIME data type guide for MariaDB. Complete reference for syntax, valid values, storage requirements, and range limits for production use.

See SQL_TSI_YEAR.

Synonym for YEAR. This keyword is an alias used for declaring a column to store year values.

See TIME.

Store time values. This type handles time durations or time of day, ranging from '-838:59:59' to '838:59:59' with optional microsecond precision.

See TIMESTAMP.

Complete TIMESTAMP data type guide for MariaDB. Complete reference for syntax, valid values, storage requirements, and range limits for production use.

See YEAR Data Type.

Store year values. This type stores a year in 2-digit or 4-digit format, supporting values from 1901 to 2155, and 0000.

This page is licensed: CC BY-SA / Gnu FDL

DATE

Syntax

```
DATE
```

Description

A date. The supported range is '`1000-01-01`' to '`9999-12-31`'. MariaDB displays `DATE` values in '`YYYY-MM-DD`' format, but can be assigned dates in looser formats, including strings or numbers, as long as they make sense. These include a short year, `YY-MM-DD`, no delimiters, `YYMMDD`, or any other acceptable delimiter, for example `YYYY/MM/DD`. For details, see date and time literals.

'`0000-00-00`' is a permitted special value (zero-date), unless the NO_ZERO_DATE SQL_MODE is used. Also, individual components of a date can be set to 0 (for example: '`2015-00-12`'), unless the NO_ZERO_IN_DATE SQL_MODE is used. In many cases, the result of en expression involving a zero-date, or a date with zero-parts, is `NULL`. If the ALLOW_INVALID_DATES `SQL_MODE` is enabled, if the day part is in the range between 1 and 31, the date does not produce any error, even for months that have less than 31 days.

Oracle Mode

In Oracle mode, `DATE` with a time portion is a synonym for DATETIME. See also mariadb_schema.

Examples

```
CREATE TABLE t1 (d DATE);

INSERT INTO t1 VALUES ("2010-01-12"), ("2011-2-28"), ('120314'),('13*04*21');

SELECT * FROM t1;
+------------+
| d          |
+------------+
| 2010-01-12 |
| 2011-02-28 |
| 2012-03-14 |
| 2013-04-21 |
+------------+
```

DATE Format

```
CREATE TABLE date_formats_example (
   description VARCHAR(30),
   example DATE
);
```

```
INSERT INTO date_formats_example VALUES
   ('Full year', '2022-12-30'),
   ('Short year', '22-12-30'),
   ('Short year no delimiters', '221230'),
   ('No delimiters', '20221230'),
   ('Pipe delimiters', '22|2|3'),
   ('Forward slash delimiter', '22/12/30'),
   ('Backward slash delimiter', '22\12\30'),
   ('Asterisk delimiter', '22*12*30'),
   ('Comma delimiter', '22,2,3');
```

The resulting data look like this:

```
SELECT * FROM date_formats_example;
```

```
+--------------------------+------------+
| description              | example    |
+--------------------------+------------+
| Full year                | 2022-12-30 |
| Short year               | 2022-12-30 |
| Short year no delimiters | 2022-12-30 |
| No delimiters            | 2022-12-30 |
| Pipe delimiters          | 2022-02-03 |
| Forward slash delimiter  | 2022-12-30 |
| Backward slash delimiter | 2022-12-30 |
| Asterisk delimiter       | 2022-12-30 |
| Comma delimiter          | 2022-02-03 |
+--------------------------+------------+
```

DATE Range

```
CREATE TABLE date_range_example (
   description VARCHAR(30),
   example DATE
);
```

```
INSERT INTO date_range_example VALUES
   ('Minimum date', '0001-01-01'),
   ('Maximum date', '9999-12-31'),
   ('Below minimum range', '0000*1*1'),
   ('Above maximum range', '10000,12,31');
```

If `SQL_MODE` is strict (the default), the example above generates the following error and no values are inserted:

```
ERROR 1292 (22007): Incorrect date value: '10000,12,31' for column `test`.`date_range_example`.`example`
at row 4
```

If `SQL_MODE` is not strict, the example above generates a warning and (possibly modified) values are inserted. The Below minimum range value is accepted because it contains a zero component. The Above maximum range value is truncated since it is an unacceptable date.

```
Warning (Code 1265): Data truncated for column 'example' at row 4
```

The resulting data would look like this:

```
SELECT * FROM date_range_example;
```

```
+--------------------+------------+
| description        | example    |
+--------------------+------------+
| Minimum date       | 0001-01-01 |
| Maximum date       | 9999-12-31 |
| Below minimum range | 0000-01-01 |
| Above maximum range | 0000-00-00 |
+--------------------+------------+
```

Date Expressions

When using a date value in an expression, such as `DATE_ADD()`, the following illustrates that a `NULL` is generated when a date value is not a real date and when a real date overflows:

```
SELECT example, DATE_ADD(example, INTERVAL 1 DAY)
   FROM date_range_example;
```

```
+------------+-----------------------------------+
| example    | DATE_ADD(example, INTERVAL 1 DAY) |
+------------+-----------------------------------+
| 0001-01-01 | 0001-01-02                        |
| 9999-12-31 | NULL                              |
| 0000-01-01 | NULL                              |
| 0000-00-00 | NULL                              |
+------------+-----------------------------------+
```

```
Warning (Code 1441): Datetime function: datetime field overflow
Warning (Code 1441): Datetime function: datetime field overflow
Warning (Code 1292): Incorrect datetime value: '0000-00-00'
```

Invalid Dates

The following example enhances the `SQL_MODE` to ensure that `ALLOW_INVALID_DATES` is set and illustrates the difference between a day that is outside the range of 1 to 31 and one that is just too large for its month:

```
-- Disable STRICT_TRANS_TABLES and enable ALLOW_INVALID_DATES
SET sql_mode=(SELECT REPLACE(@@sql_mode, 'STRICT_TRANS_TABLES', ''));
SET sql_mode=(SELECT CONCAT(@@sql_mode, ',ALLOW_INVALID_DATES'));
<</code>>

<<sql>>
INSERT INTO date_range_example VALUES
  ('day is invalid for all months', '2019-12-32'),
  ('day is just large for February', '2019-02-31');
```

```
Warning (Code 1265): Data truncated for column 'example' at row 1
```

The resulting data would look like this:

```
SELECT * FROM date_range_example;
```

```
+-------------------------------+------------+
| description                   | example    |
+-------------------------------+------------+
| day is invalid for all months  | 0000-00-00 |
| day is just large for February | 2019-02-31 |
+-------------------------------+------------+
```

DATETIME

Syntax

```
DATETIME [(microsecond precision)]
```

Description

A date and time combination.

MariaDB displays `DATETIME` values in '`YYYY-MM-DD HH:MM:SS.ffffff`' format, but allows assignment of values to `DATETIME` columns using either strings or numbers. For details, see date and time literals.

`DATETIME` columns also accept CURRENT_TIMESTAMP as the default value.

The –mysql56-temporal-format option, on by default, allows MariaDB to store `DATETME` values using the same low-level format MySQL 5.6 uses. For more information, see Internal Format, below.

For storage requirements, see Data Type Storage Requirements.

Supported Values

MariaDB stores values that use the `DATETIME` data type in a format that supports values between `1000-01-01 00:00:00.000000` and `9999-12-31 23:59:59.999999`.

MariaDB can also store microseconds with a precision between 0 and 6. If no microsecond precision is specified, then 0 is used by default.

MariaDB also supports '`0000-00-00`' as a special *zero-date* value, unless NO_ZERO_DATE is specified in the SQL_MODE. Similarly, individual components of a date can be set to `0` (for example: '`2015-00-12`'), unless NO_ZERO_IN_DATE is specified in the SQL_MODE. In many cases, the result of en expression involving a zero-date, or a date with zero-parts, is `NULL`. If the ALLOW_INVALID_DATES SQL_MODE is enabled, if the day part is in the range between 1 and 31, the date does not produce any error, even for months that have less than 31 days.

Oracle Mode

In Oracle mode, `DATE` with a time portion is a synonym for `DATETIME`. See also mariadb_schema.

Internal Format

A new temporal format was introduced from MySQL 5.6 that alters how the `TIME`, `DATETIME` and `TIMESTAMP` columns operate at lower levels. These changes allow these temporal data types to have fractional parts and negative values. You can disable this feature using the mysql56_temporal_format system variable.

Tables that include `TIMESTAMP` values that were created on an older version of MariaDB or that were created while the mysql56_temporal_format system variable was disabled continue to store data using the older data type format.

In order to update table columns from the older format to the newer format, execute an ALTER TABLE… MODIFY COLUMN statement that changes the column to the *same* data type. This change may be needed if you want to export the table's tablespace and import it onto a server that has `mysql56_temporal_format=ON` set (see MDEV-15225).

For instance, if you have a `DATETIME` column in your table:

```
SHOW VARIABLES LIKE 'mysql56_temporal_format';

+-------------------------+-------+
| Variable_name           | Value |
+-------------------------+-------+
| mysql56_temporal_format | ON    |
+-------------------------+-------+

ALTER TABLE example_table MODIFY ts_col DATETIME;
```

When MariaDB executes the ALTER TABLE statement, it converts the data from the older temporal format to the newer one.

In the event that you have several tables and columns using temporal data types that you want to switch over to the new format, make sure the system variable is enabled, then perform a dump and restore using `mysqldump`. The columns using relevant temporal data types are restored using the new temporal format.

Columns with old temporal formats are marked with a `/* mariadb-5.3 */` comment in the output of SHOW CREATE TABLE, SHOW COLUMNS, DESCRIBE statements, as well as in the `COLUMN_TYPE` column of the INFORMATION_SCHEMA.COLUMNS Table.

```
SHOW CREATE TABLE mariadb5312_datetime\G
*************************** 1. row ***************************
       Table: mariadb5312_datetime
Create Table: CREATE TABLE `mariadb5312_datetime` (
  `dt0` datetime /* mariadb-5.3 */ DEFAULT NULL,
  `dt6` datetime(6) /* mariadb-5.3 */ DEFAULT NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
```

Examples

```
CREATE TABLE t1 (d DATETIME);

INSERT INTO t1 VALUES ("2011-03-11"), ("2012-04-19 13:08:22"),
 ("2013-07-18 13:44:22.123456");

SELECT * FROM t1;
+---------------------+
| d                   |
+---------------------+
| 2011-03-11 00:00:00 |
| 2012-04-19 13:08:22 |
| 2013-07-18 13:44:22 |
+---------------------+
```

```
CREATE TABLE t2 (d DATETIME(6));

INSERT INTO t2 VALUES ("2011-03-11"), ("2012-04-19 13:08:22"),
 ("2013-07-18 13:44:22.123456");

SELECT * FROM t2;
+----------------------------+
| d                          |
+----------------------------+
| 2011-03-11 00:00:00.000000 |
| 2012-04-19 13:08:22.000000 |
| 2013-07-18 13:44:22.123456 |
+----------------------------++
```

Strings used in datetime context are automatically converted to datetime(6). If you want to have a datetime without seconds, you should use CONVERT(..,datetime).

```
SELECT CONVERT('2007-11-30 10:30:19',datetime);
+----------------------------------------+
| CONVERT('2007-11-30 10:30:19',datetime) |
+----------------------------------------+
| 2007-11-30 10:30:19                    |
+----------------------------------------+

SELECT CONVERT('2007-11-30 10:30:19',datetime(6));
+-----------------------------------------+
| CONVERT('2007-11-30 10:30:19',datetime(6)) |
+-----------------------------------------+
| 2007-11-30 10:30:19.000000                |
+-----------------------------------------+
```

DATETIME Format

```
CREATE TABLE datetime_formats_example (
  description VARCHAR(30),
  example DATETIME(6)
);
```

```
-- The time zone has no effect on the values
SET @@time_zone = '+00:00';

INSERT INTO datetime_formats_example VALUES
  ('Date without time', '2019-12-30'),
  ('Full year', '2019-12-30 00:00:00'),
  ('Short year', '19-12-30 00:00:00.000'),
  ('Pipe delimiters', '19|2|3 19|00|00.123456'),
  ('Forward slash delimiter', '19/12/30 00/00/00.0');

SET @@time_zone = '-07:00';

INSERT INTO datetime_formats_example VALUES
  ('Asterisk delimiter', '19*12*30 8*35*00'),
  ('Comma delimiter', '19,2,3 12,34,56.123');
```

The resulting data would look like this:

```
SELECT * FROM datetime_formats_example;
```

```
+------------------------+----------------------------+
| description            | example                    |
+------------------------+----------------------------+
| Date without time      | 2019-12-30 00:00:00.000000 |
| Full year              | 2019-12-30 00:00:00.000000 |
| Short year             | 2019-12-30 00:00:00.000000 |
| Pipe delimiters        | 2019-02-03 19:00:00.123456 |
| Forward slash delimiter | 2019-12-30 00:00:00.000000 |
| Asterisk delimiter     | 2019-12-30 08:35:00.000000 |
| Comma delimiter        | 2019-02-03 12:34:56.123000 |
+------------------------+----------------------------+
```

The default microsecond precision when unspecified is 0, and you can use that in a cast in order to trim off stored microseconds:

```
SELECT description, CONVERT(example, DATETIME) AS example
  FROM datetime_formats_example;

+-------------------------+---------------------+
| description             | example             |
+-------------------------+---------------------+
| Date without time       | 2019-12-30 00:00:00 |
| Full year               | 2019-12-30 00:00:00 |
| Short year              | 2019-12-30 00:00:00 |
| Pipe delimiters         | 2019-02-03 19:00:00 |
| Forward slash delimiter | 2019-12-30 00:00:00 |
| Asterisk delimiter      | 2019-12-30 08:35:00 |
| Comma delimiter         | 2019-02-03 12:34:56 |
+-------------------------+---------------------+
```

SQL_TSI_YEAR

Overview

See YEAR.

EXAMPLES

```
CREATE TABLE sql_tsi_year_example (
  example SQL_TSI_YEAR
);
```

```
SHOW CREATE TABLE sql_tsi_year_example\G
```

```
*************************** 1. row ***************************
       Table: sql_tsi_year_example
Create Table: CREATE TABLE `sql_tsi_year_example` (
  `example` year(4) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

This page is: Copyright © 2026 MariaDB. All rights reserved.

TIME

Syntax

```
TIME [(<microsecond precision>)]
```

Description

A time. The range is `'-838:59:59.999999'` to `'838:59:59.999999'`. Microsecond precision can be from 0-6; if not specified 0 is used.

MariaDB displays `TIME` values in `'HH:MM:SS.ssssss'` format, but allows assignment of times in looser formats, including 'D HH:MM:SS', 'HH:MM:SS', 'HH:MM', 'D HH:MM', 'D HH', 'SS', or 'HHMMSS', as well as permitting dropping of any leading zeros when a delimiter is provided, for example '3:9:10'. For details, see date and time literals.

The –mysql56-temporal-format option, on by default, allows MariaDB to store `TIME` values using the same low-level format MySQL 5.6 uses.

Internal Format

A new temporal format was introduced from MySQL 5.6 that alters how the `TIME`, `DATETIME` and `TIMESTAMP` columns operate at lower levels. These changes allow these temporal data types to have fractional parts and negative values. You can disable this feature using the mysql56_temporal_format system variable.

Tables that include `TIMESTAMP` values that were created on an older version of MariaDB or that were created while the mysql56_temporal_format system variable was disabled continue to store data using the older data type format.

In order to update table columns from the older format to the newer format, execute an ALTER TABLE… MODIFY COLUMN statement that changes the column to the *same* data type. This change may be needed if you want to export the table's tablespace and import it onto a server that has `mysql56_temporal_format=ON` set (see MDEV-15225).

For instance, if you have a `TIME` column in your table:

```
SHOW VARIABLES LIKE 'mysql56_temporal_format';

+-------------------------+-------+
| Variable_name           | Value |
+-------------------------+-------+
| mysql56_temporal_format | ON    |
+-------------------------+-------+

ALTER TABLE example_table MODIFY ts_col TIME;
```

When MariaDB executes the ALTER TABLE statement, it converts the data from the older temporal format to the newer one.

In the event that you have several tables and columns using temporal data types that you want to switch over to the new format, make sure the system variable is enabled, then perform a dump and restore using `mariadb-dump`. The columns using relevant temporal data types are restored using the new temporal format.

Columns with old temporal formats are marked with a `/* mariadb-5.3 */` comment in the output of SHOW CREATE TABLE, SHOW COLUMNS, DESCRIBE statements, as well as in the `COLUMN_TYPE` column of the INFORMATION_SCHEMA.COLUMNS Table.

```
SHOW CREATE TABLE mariadb5312_time\G
*************************** 1. row ***************************
       Table: mariadb5312_time
Create Table: CREATE TABLE `mariadb5312_time` (
  `t0` time /* mariadb-5.3 */ DEFAULT NULL,
  `t6` time(6) /* mariadb-5.3 */ DEFAULT NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
```

> **Warning:**
>
> Columns with the current format are not marked with a comment.

Examples

```
INSERT INTO time VALUES ('90:00:00'), ('800:00:00'), (800), (22), (151413), ('9:6:3'), ('12 09');

SELECT * FROM time;
+-----------+
| t         |
+-----------+
| 90:00:00  |
| 800:00:00 |
| 00:08:00  |
| 00:00:22  |
| 15:14:13  |
| 09:06:03  |
| 297:00:00 |
+-----------+
```

Time example:

```
CREATE TABLE time_example (
  description VARCHAR(30),
  example TIME(6)
);
```

```
INSERT INTO time_example VALUES
  ('HH:MM:SS', '12:34:56'),
  ('HHMMSS', '123456'),
  ('SS.microsec', '42.123456');
```

The resulting data look like this:

```
SELECT * FROM time_example;
```

```
+-------------+-----------------+
| description | example         |
+-------------+-----------------+
| HH:MM:SS    | 12:34:56.000000 |
| HHMMSS      | 12:34:56.000000 |
| SS.microsec | 00:00:42.123456 |
+-------------+-----------------+
```

- Data Type Storage Requirements

This page is licensed: GPLv2, originally from fill_help_tables.sql

TIMESTAMP

This page is about the `TIMESTAMP` **data type**. For the timestamp function, see TIMESTAMP FUNCTION.

Syntax

```
TIMESTAMP [(<microsecond precision)]
```

Description

A timestamp in the format `YYYY-MM-DD HH:MM:SS.ffffff`.

The timestamp field is generally used to define at which moment in time a row was added or updated and by default will automatically be assigned the current datetime when a record is inserted or updated. The automatic properties

only apply to the first `TIMESTAMP` in the record; subsequent `TIMESTAMP` columns will not be changed.

MariaDB includes the –mysql56-temporal-format option, on by default, which allows MariaDB to store `TIMESTAMP` values using the same low-level format MySQL 5.6 uses.

For more information, see Internal Format.

Supported Values

> **CURRENT**
>
> MariaDB stores values that use the `TIMESTAMP` data type as the number of seconds since '1970-01-01 00:00:00' (UTC). This means that the `TIMESTAMP` data type can hold values between '1970-01-01 00:00:01' (UTC) and '2106-02-07 06:28:15 UTC'.
>
> **< 11.5**
>
> MariaDB stores values that use the `TIMESTAMP` data type as the number of seconds since '1970-01-01 00:00:00' (UTC). This means that the `TIMESTAMP` data type can hold values between '1970-01-01 00:00:01' (UTC) and '2038-01-19 03:14:07' (UTC).

MariaDB can also store microseconds with a precision between 0 and 6. If no microsecond precision is specified, then 0 is used by default.

Automatic Values

MariaDB has special behavior for the first column that uses the `TIMESTAMP` data type in a specific table when the system variable explicit_defaults_for_timestamp is not set (which was the default until MariaDB 10.10). For the first column that uses the `TIMESTAMP` data type in a specific table, MariaDB automatically assigns the following properties to the column:

- `DEFAULT CURRENT_TIMESTAMP`
- `ON UPDATE CURRENT_TIMESTAMP`

This means that if the column is not explicitly assigned a value in an `INSERT` or `UPDATE` query, then MariaDB will automatically initialize the column's value with the current date and time.

This automatic initialization for `INSERT` and `UPDATE` queries can also be **explicitly enabled** for a column that uses the `TIMESTAMP` data type by specifying the `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` clauses for the column. In these clauses, any synonym of CURRENT_TIMESTAMP is accepted, including `CURRENT_TIMESTAMP()`, `NOW()`, `LOCALTIME`, `LOCALTIME()`, `LOCALTIMESTAMP`, and `LOCALTIMESTAMP()`.

This automatic initialization for `INSERT` queries can also be **explicitly disabled** for a column that uses the `TIMESTAMP` data type by specifying a constant `DEFAULT` value. For example, `DEFAULT 0`.

This automatic initialization for `UPDATE` queries can also be **explicitly disabled** for a column that uses the `TIMESTAMP` data type by specifying a `DEFAULT` clause for the column, but no `ON UPDATE` clause. If a `DEFAULT` clause is explicitly specified for a column that uses the `TIMESTAMP` data type, but an `ON UPDATE` clause is not specified for the column, then the timestamp value will not automatically change when an `UPDATE` statement is executed.

MariaDB also has special behavior if `NULL` is assigned to column that uses the `TIMESTAMP` data type. If the column is assigned the `NULL` value in an `INSERT` or `UPDATE` query, then MariaDB will automatically initialize the column's value with the current date and time. For details, see NULL values in MariaDB.

This automatic initialization for `NULL` values can also be **explicitly disabled** for a column that uses the `TIMESTAMP` data type by specifying the `NULL` attribute for the column. In this case, if the column's value is set to `NULL`, then the

column's value will actually be set to `NULL`.

Time Zones

If a column uses the `TIMESTAMP` data type, then any inserted values are converted from the session's time zone to Coordinated Universal Time (UTC) when stored, and converted back to the session's time zone when retrieved.

MariaDB validates `TIMESTAMP` literals against the session's time zone. For example, if a specific time range never occurred in a specific time zone due to daylight savings time, then `TIMESTAMP` values within that range would be invalid for that time zone.

MariaDB does not store any time zone identifier with the value of the `TIMESTAMP` data type. See MDEV-10018 for more information.

MariaDB does not support time zone literals that contain time zone identifiers. See MDEV-11829 for more information.

Limitations

- Because the `TIMESTAMP` value is stored as Epoch Seconds, the timestamp value '1970-01-01 00:00:00' (UTC) is reserved since the second #0 is used to represent '0000-00-00 00:00:00'.

SQL_MODE=MAXDB

If the SQL_MODE is set to `MAXDB`, TIMESTAMP fields will be silently converted to DATETIME.

Internal Format

A temporal format was introduced from MySQL 5.6 that alters how the `TIME`, `DATETIME` and `TIMESTAMP` columns operate at lower levels. These changes allow these temporal data types to have fractional parts and negative values. You can disable this feature using the mysql56_temporal_format system variable.

Tables that include `TIMESTAMP` values that were created on an older version of MariaDB or that were created while the mysql56_temporal_format system variable was disabled continue to store data using the older data type format.

In order to update table columns from the older format to the newer format, execute an ALTER TABLE… MODIFY COLUMN statement that changes the column to the *same* data type. This change may be needed if you want to export the table's tablespace and import it onto a server that has `mysql56_temporal_format=ON` set (see MDEV-15225).

For instance, if you have a `TIMESTAMP` column in your table:

```
SHOW VARIABLES LIKE 'mysql56_temporal_format';

+-------------------------+-------+
| Variable_name           | Value |
+-------------------------+-------+
| mysql56_temporal_format | ON    |
+-------------------------+-------+

ALTER TABLE example_table MODIFY ts_col TIMESTAMP;
```

When MariaDB executes the ALTER TABLE statement, it converts the data from the older temporal format to the newer one.

In the event that you have several tables and columns using temporal data types that you want to switch over to the new format, make sure the system variable is enabled, then perform a dump and restore using mariadb-dump. The columns using relevant temporal data types are restored using the new temporal format.

> **CURRENT**

Columns with old temporal formats are marked with a `/* mariadb-5.3 */` comment in the output of SHOW CREATE TABLE, SHOW COLUMNS, DESCRIBE statements, as well as in the `COLUMN_TYPE` column of the INFORMATION_SCHEMA.COLUMNS Table.

< 10.5.1

Columns with old temporal formats are **not** marked with a `/* mariadb-5.3 */` comment in the output of SHOW CREATE TABLE, SHOW COLUMNS, DESCRIBE statements, as well as in the `COLUMN_TYPE` column of the INFORMATION_SCHEMA.COLUMNS Table.

```
SHOW CREATE TABLE mariadb5312_timestamp\G
*************************** 1. row ***************************
       Table: mariadb5312_timestamp
Create Table: CREATE TABLE `mariadb5312_timestamp` (
  `ts0` timestamp /* mariadb-5.3 */ NOT NULL DEFAULT current_timestamp() ON UPDATE current_timestamp(),
  `ts6` timestamp(6) /* mariadb-5.3 */ NOT NULL DEFAULT '0000-00-00 00:00:00.000000'
) ENGINE=MyISAM DEFAULT CHARSET=latin1
```

Examples

```
CREATE TABLE t (id INT, ts TIMESTAMP);

DESC t;
+-------+-----------+------+-----+-------------------+-----------------------------+
| Field | Type      | Null | Key | Default           | Extra                       |
+-------+-----------+------+-----+-------------------+-----------------------------+
| id    | int(11)   | YES  |     | NULL              |                             |
| ts    | timestamp | NO   |     | CURRENT_TIMESTAMP | on update CURRENT_TIMESTAMP |
+-------+-----------+------+-----+-------------------+-----------------------------+

INSERT INTO t(id)  VALUES (1),(2);

SELECT * FROM t;
+------+---------------------+
| id   | ts                  |
+------+---------------------+
|    1 | 2013-07-22 12:50:05 |
|    2 | 2013-07-22 12:50:05 |
+------+---------------------+

INSERT INTO t  VALUES (3,NULL),(4,'2001-07-22 12:12:12');

SELECT * FROM t;
+------+---------------------+
| id   | ts                  |
+------+---------------------+
|    1 | 2013-07-22 12:50:05 |
|    2 | 2013-07-22 12:50:05 |
|    3 | 2013-07-22 12:51:56 |
|    4 | 2001-07-22 12:12:12 |
+------+---------------------+
```

Converting to Unix epoch:

```
SELECT ts, UNIX_TIMESTAMP(ts) FROM t;
+---------------------+--------------------+
| ts                  | UNIX_TIMESTAMP(ts) |
+---------------------+--------------------+
| 2013-07-22 12:50:05 |         1374490205 |
| 2013-07-22 12:50:05 |         1374490205 |
| 2013-07-22 12:51:56 |         1374490316 |
| 2001-07-22 12:12:12 |          995796732 |
+---------------------+--------------------+
```

Update also changes the timestamp:

```
UPDATE t set id=5 WHERE id=1;

SELECT * FROM t;
+------+---------------------+
| id   | ts                  |
+------+---------------------+
|    5 | 2013-07-22 14:52:33 |
|    2 | 2013-07-22 12:50:05 |
|    3 | 2013-07-22 12:51:56 |
|    4 | 2001-07-22 12:12:12 |
+------+---------------------+
```

Default `NULL` :

```
CREATE TABLE t2 (id INT, ts TIMESTAMP NULL ON UPDATE CURRENT_TIMESTAMP);

INSERT INTO t(id)  VALUES (1),(2);

SELECT * FROM t2;

INSERT INTO t2(id)  VALUES (1),(2);

SELECT * FROM t2;
+------+------+
| id   | ts   |
+------+------+
|    1 | NULL |
|    2 | NULL |
+------+------+

UPDATE t2 SET id=3 WHERE id=1;

SELECT * FROM t2;
+------+---------------------+
| id   | ts                  |
+------+---------------------+
|    3 | 2013-07-22 15:32:22 |
|    2 | NULL                |
+------+---------------------+
```

Only the first timestamp is automatically inserted and updated:

```
CREATE TABLE t3 (id INT, ts1 TIMESTAMP, ts2 TIMESTAMP);

INSERT INTO t3(id)  VALUES (1),(2);

SELECT * FROM t3;
+------+---------------------+---------------------+
| id   | ts1                 | ts2                 |
+------+---------------------+---------------------+
|    1 | 2013-07-22 15:35:07 | 0000-00-00 00:00:00 |
|    2 | 2013-07-22 15:35:07 | 0000-00-00 00:00:00 |
+------+---------------------+---------------------+

DESC t3;
+-------+-----------+------+-----+---------------------+-----------------------------+
| Field | Type      | Null | Key | Default             | Extra                       |
+-------+-----------+------+-----+---------------------+-----------------------------+
| id    | int(11)   | YES  |     | NULL                |                             |
| ts1   | timestamp | NO   |     | CURRENT_TIMESTAMP   | on update CURRENT_TIMESTAMP |
| ts2   | timestamp | NO   |     | 0000-00-00 00:00:00 |                             |
+-------+-----------+------+-----+---------------------+-----------------------------+
```

Explicitly setting a timestamp with the CURRENT_TIMESTAMP function:

```
INSERT INTO t3(id,ts2)  VALUES (3,CURRENT_TIMESTAMP());

SELECT * FROM t3;
+------+---------------------+---------------------+
| id   | ts1                 | ts2                 |
+------+---------------------+---------------------+
|    1 | 2013-07-22 15:35:07 | 0000-00-00 00:00:00 |
|    2 | 2013-07-22 15:35:07 | 0000-00-00 00:00:00 |
|    3 | 2013-07-22 15:38:52 | 2013-07-22 15:38:52 |
+------+---------------------+---------------------+
```

Specifying the timestamp as `NOT NULL`:

```
CREATE TABLE t4 (id INT, ts TIMESTAMP NOT NULL);

INSERT INTO t4(id)  VALUES (1);
SELECT SLEEP(1);
INSERT INTO t4(id,ts) VALUES (2,NULL);

SELECT * FROM t4;
```

YEAR Data Type

> **Note:**
>
> This page is about the `YEAR` **data type**, not the `YEAR` function.

Syntax

```
YEAR[(4)]
```

Description

A year in four-digit format. The two-digit format (`YEAR(2)`), while supported, is error-prone and has been deprecated since 2012. As of MariaDB 13.0, `YEAR(2)` is no longer accepted by default; set `old_mode=2_DIGIT_YEAR` to allow it again. That setting is itself deprecated and is intended only as a temporary migration aid.

In four-digit format, the allowable values are 1901 to 2155, and 0000. In two-digit format, the allowable values are 70 to 69, representing years from 1970 to 2069. MariaDB displays YEAR values in YYYY format, but allows you to assign values to `YEAR` columns using either strings or numbers.

Inserting numeric zero has a different result for `YEAR(4)` and `YEAR(2)`. For `YEAR(2)`, the value `00` reflects the year 2000. For `YEAR(4)`, the value `0000` reflects the year zero. This only applies to numeric zero. String zero always reflects the year 2000.

Examples

Accepting a string or a number:

```
CREATE TABLE y(y YEAR);

INSERT INTO y VALUES (1990),('2012');

SELECT * FROM y;
+------+
| y    |
+------+
| 1990 |
| 2012 |
+------+
```

With strict_mode set — values out of range:

```
INSERT INTO y VALUES (1005),('3080');
ERROR 1264 (22003): Out of range value for column 'y' at row 1

INSERT INTO y VALUES ('2013-12-12');
ERROR 1265 (01000): Data truncated for column 'y' at row 1

SELECT * FROM y;
+------+
| y    |
+------+
| 1990 |
| 2012 |
+------+
```

With strict_mode unset — values out of range:

```
INSERT INTO y VALUES (1005),('3080');
Query OK, 2 rows affected, 2 warnings (0.05 sec)
Records: 2  Duplicates: 0  Warnings: 2

SHOW WARNINGS;
+---------+------+-------------------------------------------+
| Level   | Code | Message                                   |
+---------+------+-------------------------------------------+
| Warning | 1264 | Out of range value for column 'y' at row 1 |
| Warning | 1264 | Out of range value for column 'y' at row 2 |
+---------+------+-------------------------------------------+

SELECT * FROM y;
+------+
| y    |
+------+
| 1990 |
| 2012 |
| 0000 |
| 0000 |
+------+
```

Truncating:

```
INSERT INTO y VALUES ('2013-12-12');
Query OK, 1 row affected, 1 warning (0.05 sec)

SHOW WARNINGS;
+---------+------+----------------------------------------+
| Level   | Code | Message                                |
+---------+------+----------------------------------------+
| Warning | 1265 | Data truncated for column 'y' at row 1 |
+---------+------+----------------------------------------+

SELECT * FROM y;
+------+
| y    |
+------+
| 1990 |
| 2012 |
| 0000 |
| 0000 |
| 2013 |
+------+
```

Difference between `YEAR(2)` and `YEAR(4)`, and string and numeric zero:

```
CREATE TABLE y2(y YEAR(4), y2 YEAR(2));
Query OK, 0 rows affected, 1 warning (0.40 sec)

Note (Code 1287): 'YEAR(2)' is deprecated and will be removed in a future release. Please use YEAR(4)
instead

INSERT INTO y2 VALUES(0,0),('0','0');

SELECT YEAR(y),YEAR(y2) FROM y2;
+---------+----------+
| YEAR(y) | YEAR(y2) |
+---------+----------+
|       0 |     2000 |
|    2000 |     2000 |
+---------+----------+
```

String Data Types

See BLOB and TEXT Data Types.

Overview of large object types. This page compares BLOB (binary) and TEXT (character) types, explaining their storage and usage differences.

See BINARY.

Fixed-length binary string type. This type stores a fixed number of bytes, padding with zero bytes if the data is shorter.

See BLOB.

Variable-length binary large object. BLOB columns can store binary data up to 65,535 bytes, suitable for images or other non-text files.

See CHAR.

Fixed-length character string type. CHAR columns store strings of a specified length (0 to 255), padding with spaces if necessary.

See CHARACTER.

Fixed-length character string type. CHARACTER columns store strings of a specified length (0 to 255), padding with spaces if necessary.

See CHAR BYTE.

Fixed-length binary string type. This type stores a fixed number of bytes, padding with zero bytes if the data is shorter.

See CHAR VARYING.

CHAR VARYING is a synonym for the VARCHAR string data type.

See CLOB.

In Oracle mode, CLOB is an alias for the LONGTEXT data type used to store large text objects.

See ENUM.

Complete ENUM type reference: ENUM('v1','v2') syntax, CHARACTER SET/COLLATE options, NULL/empty string defaults, and numeric index sorting guidelines.

See INET4.

IPv4 address data type. Stores IPv4 addresses as 4-byte binary strings for efficient storage and retrieval.

See INET6.

IPv6 address data type. Stores IPv6 addresses as 16-byte binary strings, also supporting IPv4 addresses via mapping.

See JSON Data Type.

Complete JSON Data Type data type guide for MariaDB. Complete reference for syntax, valid values, storage requirements, and range limits for production use.

See LONG and LONG VARCHAR.

LONG and LONG VARCHAR are compatibility synonyms for the MEDIUMTEXT string data type.

See LONG CHAR VARYING.

LONG CHAR VARYING is a compatibility synonym for the MEDIUMTEXT string data type.

See LONG CHARACTER VARYING.

LONG CHARACTER VARYING is a compatibility synonym for the MEDIUMTEXT string data type.

See LONG VARBINARY.

LONG VARBINARY is a compatibility synonym for the MEDIUMBLOB binary data type.

See LONG VARCHAR.

LONG VARCHAR is a compatibility synonym for the MEDIUMTEXT string data type.

See LONG VARCHARACTER.

LONG VARCHARACTER is a compatibility synonym for the MEDIUMTEXT string data type.

See LONGBLOB.

Very large binary object. A LONGBLOB column can store up to 4GB of binary data.

See LONGTEXT.

Complete LONGTEXT type reference: 4GB (2^32-1) storage limit, CHARACTER SET/COLLATE syntax, max_allowed_packet constraints, and JSON/CLOB aliases.

See MEDIUMBLOB.

Medium-sized binary object. A MEDIUMBLOB column can store up to 16MB of binary data.

See MEDIUMTEXT.

Medium-sized character string. A MEDIUMTEXT column can store up to 16MB of text data.

See NATIONAL CHAR.

NATIONAL CHAR is a synonym for the CHAR data type that uses the predefined utf8mb3 character set.

See NATIONAL CHAR VARYING.

NATIONAL CHAR VARYING is a synonym for VARCHAR that uses the predefined utf8 character set.

See NATIONAL CHARACTER VARYING.

NATIONAL CHARACTER VARYING is a synonym for VARCHAR using the predefined utf8 character set.

See NATIONAL CHARACTER.

NATIONAL CHARACTER is a synonym for the CHAR data type using the predefined utf8 character set.

See NATIONAL VARCHAR.

NATIONAL VARCHAR is a synonym for the VARCHAR data type using the predefined utf8 character set.

See NATIONAL VARCHARACTER.

NATIONAL VARCHARACTER is a synonym for VARCHAR using the predefined utf8 character set.

See NCHAR.

NCHAR is a synonym for the fixed-length CHAR string data type using the utf8mb3 character set.

See NCHAR VARCHAR.

NCHAR VARCHAR is a synonym for the VARCHAR string data type using the utf8 character set.

See NCHAR VARCHARACTER.

NCHAR VARCHARACTER is a synonym for VARCHAR using the utf8 character set.

See NCHAR VARYING.

NCHAR VARYING is a synonym for the VARCHAR string data type using the utf8 character set.

See RAW.

In Oracle mode, RAW is a variable-length binary data type synonymous with VARBINARY.

See ROW.

ROW is a data type used in stored programs to store a complete row of data from a cursor or table.

See SET Data Type.

String object with zero or more values from a predefined list. A SET column can store multiple values selected from a list of permitted strings.

See TEXT.

Complete TEXT type reference: TEXT(M) syntax, 65,535 byte maximum, 2-byte length prefix, DEFAULT value support, and indexing constraints rules.

See TINYBLOB.

Very small binary object. A TINYBLOB column can store up to 255 bytes of binary data.

See TINYTEXT.

Very small character string. A TINYTEXT column can store up to 255 characters.

See UUID Data Type.

Official UUID data type reference: 128-bit storage optimization, CAST from CHAR/VARCHAR/BINARY types, RFC4122 string format, and UUIDv6/v7 support.

See VARBINARY.

Variable-length binary string type. VARBINARY columns store binary strings of variable length up to a specified maximum.

See VARCHAR.

Complete VARCHAR reference: VARCHAR(M) syntax, length limits (0-65532 per row), CHARACTER SET/COLLATE options, indexing rules, and trailing spaces.

See VARCHAR2.

Variable-length character string type. VARCHAR2 columns store strings of variable length up to a specified maximum (up to 65,535).

See VARCHARACTER.

Variable-length character string type. VARCHARACTER columns store strings of variable length up to a specified maximum (up to 65,535).

See XMLTYPE.

The XMLTYPE data type, available from MariaDB 12.3, for storing XML data.

See Character Sets and Collations.

Learn about character sets in MariaDB Server. This section details how different character sets and collations impact string storage, comparison, and sorting within your database.

BLOB and TEXT Data Types

Description

A `BLOB` is a binary large object that can hold a variable amount of data. The four `BLOB` types are

- TINYBLOB,
- BLOB,
- MEDIUMBLOB, and
- LONGBLOB.

These differ only in the maximum length of the values they can hold.

The `TEXT` types are

- TINYTEXT,

- TEXT,
- MEDIUMTEXT, and
- LONGTEXT.
- JSON (alias for LONGTEXT)

These correspond to the four `BLOB` types and have the same maximum lengths and storage requirements.

`BLOB` and `TEXT` columns can have a `DEFAULT` value.

> **Note:**
>
> It is possible to set a unique index on columns that use the `BLOB` or `TEXT` data types.

Handling Large Data via APIs

When working with very large `BLOB` or `TEXT` values, the data may exceed the limit set by the max_allowed_packet system variable. To avoid this—and to reduce memory consumption on the client—most MariaDB connectors allow you to "stream" data in chunks.

- Connector/C: Use mysql_stmt_send_long_data() to send parameter data in pieces before calling mysql_stmt_execute(). This bypasses `max_allowed_packet` limits and reduces the peak memory footprint (RSS) of the application.
- Connector/J: Use `PreparedStatement.setBinaryStream()` (for `BLOB`) or `PreparedStatement.setCharacterStream()` (for `TEXT`).
- Protocol: These APIs utilize the COM_STMT_SEND_LONG_DATA command, which appends data to a parameter on the server side.

Technical Rules for C/C++

- 0-Based Indexing: Parameter numbering starts at `0`.
- The `is_null` Flag: This must be `0`; if set to nonzero, the server may discard the streamed data.
- Resetting: Use mysql_stmt_reset() to clear all accumulated long data on the server if you need to abort or retry.
- Chunk Size: A practical performance "sweet spot" is between `64` KB and `1` MB per chunk.

BINARY

This page describes the BINARY data type. For details about the operator, see Binary Operator.

Syntax

```
BINARY(M)
```

Description

The `BINARY` type is similar to the CHAR type, but stores binary byte strings rather than non-binary character strings. `M` represents the column length in bytes.

It contains no character set, and comparison and sorting are based on the numeric value of the bytes.

If the maximum length is exceeded, and SQL strict mode is not enabled , the extra characters will be dropped with a warning. If strict mode is enabled, an error will occur.

`BINARY` values are right-padded with `0x00` (the zero byte) to the specified length when inserted. The padding is *not* removed on select, so this needs to be taken into account when sorting and comparing, where all bytes are significant. The zero byte, `0x00` is less than a space for comparison purposes.

Use Cases for Zero Length

A `BINARY(0)` or `VARBINARY(0)` column is restricted to an empty byte string or `NULL`.

- **Schema Preservation**: Use these columns when a system expects a specific column to exist, but no data storage is required for your current application.
- **Space-Efficient Indicators**: These columns can act as a two-state indicator where the presence of an empty byte string represents one state and `NULL` represents another.

If you attempt to insert a value other than an empty string, MariaDB returns an `ERROR 1406 (22001)` indicating the data is too long for the column.

Examples

Inserting too many characters, first with strict mode off, then with it on:

```
CREATE TABLE bins (a BINARY(10));

INSERT INTO bins VALUES('12345678901');
Query OK, 1 row affected, 1 warning (0.04 sec)

SELECT * FROM bins;
+------------+
| a          |
+------------+
| 1234567890 |
+------------+

SET sql_mode='STRICT_ALL_TABLES';

INSERT INTO bins VALUES('12345678901');
ERROR 1406 (22001): Data too long for column 'a' at row 1
```

Sorting is performed with the byte value:

```
TRUNCATE bins;

INSERT INTO bins VALUES('A'),('B'),('a'),('b');

SELECT * FROM bins ORDER BY a;
+------+
| a    |
+------+
| A    |
| B    |
| a    |
| b    |
+------+
```

Using CAST to sort as a CHAR instead:

```
SELECT * FROM bins ORDER BY CAST(a AS CHAR);
+------+
| a    |
+------+
| a    |
| A    |
| b    |
| B    |
+------+
```

The field is a `BINARY(10)`, so padding of two '\0's are inserted, causing comparisons that don't take this into account to fail:

```
TRUNCATE bins;

INSERT INTO bins VALUES('12345678');

SELECT a = '12345678', a = '12345678\0\0' from bins;
+----------------+--------------------+
| a = '12345678' | a = '12345678\0\0' |
+----------------+--------------------+
|              0 |                  1 |
+----------------+--------------------+
```

Example of `BINARY`:

```
CREATE TABLE binary_example (
   description VARCHAR(20),
   example BINARY(255)
) DEFAULT CHARSET=latin1; -- One byte per char makes the examples clearer

INSERT INTO binary_example VALUES
   ('Normal foo', 'foo'),
   ('Trailing spaces foo', 'foo      '),
   ('NULLed', NULL),
   ('Empty', ''),
   ('Maximum', RPAD('', 255, CHAR(7)));

SELECT description, LENGTH(example) AS length
   FROM binary_example;

+---------------------+--------+
| description         | length |
+---------------------+--------+
| Normal foo          |    255 |
| Trailing spaces foo |    255 |
| NULLed              |   NULL |
| Empty               |    255 |
| Maximum             |    255 |
+---------------------+--------+
```

Data Too Long

When `SQL_MODE` is strict (the default), a value is considered "too long" when its length exceeds the size of the data type, and an error is generated.

Example of data too long behavior for `BINARY`:

```
TRUNCATE binary_example;

INSERT INTO binary_example VALUES
   ('Overflow', RPAD('', 256, CHAR(7)));

ERROR 1406 (22001): Data too long for column 'example' at row 1
```

See Also

- CHAR
- Data Type Storage Requirements

This page is licensed: GPLv2, originally from fill_help_tables.sql

BLOB

Syntax

```
BLOB[(M)]
```

Description

> **Note:**
>
> If you are handling large binary data that exceeds the `max_allowed_packet` limit, you can stream the data in chunks using specialized API functions like `mysql_stmt_send_long_data()` or `setBinaryStream()`. See Handling Large Data via APIs for more details.

A `BLOB` column with a maximum length of 65,535 (2^{16} - 1) bytes. Each `BLOB` value is stored using a two-byte length prefix that indicates the number of bytes in the value.

An optional length `M` can be given for this type. If this is done, MariaDB creates the column as the smallest `BLOB` type large enough to hold values *`M`* bytes long.

`BLOB` values can also be used to store dynamic columns.

`BLOB` and `TEXT` columns can both be assigned a DEFAULT value.

Indexing

On a column that uses the `BLOB` data type, setting a unique index is now possible.

Note

In previous releases, setting a unique index on a column that uses the `BLOB` data type was not possible. Index would only guarantee the uniqueness of a fixed number of characters.

Oracle Mode

In Oracle mode, `BLOB` is a synonym for `LONGBLOB`.

EXAMPLES

BLOB

Example of `BLOB`:

```
CREATE TABLE blob_example (
   description VARCHAR(20),
   example BLOB
) DEFAULT CHARSET=latin1; -- One byte per char makes the examples clearer
```

```
INSERT INTO blob_example VALUES
   ('Normal foo', 'foo'),
   ('Trailing spaces foo', 'foo      '),
   ('NULLed', NULL),
   ('Empty', ''),
   ('Maximum', RPAD('', 65535, CHAR(7)));
```

```
SELECT description, LENGTH(example) AS length
   FROM blob_example;

+---------------------+--------+
| description         | length |
+---------------------+--------+
| Normal foo          |      3 |
| Trailing spaces foo |      9 |
| NULLed              |   NULL |
| Empty               |      0 |
| Maximum             |  65535 |
+---------------------+--------+
```

Data Too Long

When `SQL_MODE` is strict (the default) a value is considered "too long" when its length exceeds the size of the data type, and an error is generated.

Example of data too long behavior for `BLOB`:

```
TRUNCATE blob_example;

INSERT INTO blob_example VALUES
   ('Overflow', RPAD('', 65536, CHAR(7)));

ERROR 1406 (22001): Data too long for column 'example' at row 1
```

CHAR

> **Note:**
>
> This page covers the `CHAR` data type. See CHAR Function for the function.

Syntax

```
[NATIONAL] CHAR[(M)] [CHARACTER SET charset_name] [COLLATE collation_name]
```

Description

A fixed-length string that is always right-padded with spaces to the specified length when stored. `M` represents the column length in characters. The range of `M` is `0` to `255`. If `M` is omitted, the length is `1`.

> **Note:**
>
> Trailing spaces are removed when `CHAR` values are retrieved unless the `PAD_CHAR_TO_FULL_LENGTH` SQL mode is enabled.

If a unique index consists of a column where trailing pad characters are stripped or ignored, inserts into that column where values differ only by the number of trailing pad characters will result in a duplicate-key error.

`CHAR(0)` columns can contain 2 values: an empty string or `NULL`. Such columns cannot be part of an index. The CONNECT storage engine does not support `CHAR(0)`.

Use Cases for Zero Length

A `CHAR(0)` or `VARCHAR(0)` column occupies minimal space and is restricted to two possible values: an empty string (`''`) or `NULL`. You can use these columns for the following purposes:

- **Legacy Compatibility**: Include these columns to maintain compatibility with older applications that require a specific table schema, even if the data is no longer collected.
- **Two-State Flags**: A `CHAR(0) NULL` column can function as a boolean indicator. It uses only one bit of storage to distinguish between a "set" state (the empty string) and an "unset" state (`NULL`).
- **Row Marking**: You can use a `CHAR(0)` column to mark a specific row in a table. For example, if you require only one "active" row, set that row to an empty string while keeping all other rows `NULL`.

The following error occurs if you attempt to insert any character data into a 0-length column: `ERROR 1406 (22001): Data too long for column`.

Examples

Trailing spaces:

```
CREATE TABLE strtest (c CHAR(10));
INSERT INTO strtest VALUES('Maria   ');

SELECT c='Maria',c='Maria   ' FROM strtest;
+-----------+--------------+
| c='Maria' | c='Maria   ' |
+-----------+--------------+
|         1 |            1 |
+-----------+--------------+

SELECT c LIKE 'Maria',c LIKE 'Maria   ' FROM strtest;
+----------------+-------------------+
| c LIKE 'Maria' | c LIKE 'Maria   ' |
+----------------+-------------------+
|              1 |                 0 |
+----------------+-------------------+
```

Example of `CHAR`:

```
CREATE TABLE char_example (
   description VARCHAR(20),
   example CHAR(255)
) DEFAULT CHARSET=latin1; -- One byte per char makes the examples clearer
```

```
INSERT INTO char_example VALUES
   ('Normal foo', 'foo'),
   ('Trailing spaces foo', 'foo      '),
   ('NULLed', NULL),
   ('Empty', ''),
   ('Maximum', RPAD('', 255, 'x'));
```

```
SELECT description, LENGTH(example) AS length FROM char_example;

+---------------------+--------+
| description         | length |
+---------------------+--------+
| Normal foo          |      3 |
| Trailing spaces foo |      3 |
| NULLed              |   NULL |
| Empty               |      0 |
| Maximum             |    255 |
+---------------------+--------+
```

Data Too Long

When `SQL_MODE` is strict (the default), a value is considered "too long" when its length exceeds the size of the data type, and an error is generated.

Example of data too long behavior for `CHAR`:

```
TRUNCATE char_example;

INSERT INTO char_example VALUES
   ('Overflow', RPAD('', 256, 'x'));

ERROR 1406 (22001): Data too long for column 'example' at row 1
```

NO PAD Collations

`NO PAD` collations regard trailing spaces as normal characters. You can get a list of all `NO PAD` collations by querying the Information Schema Collations table, for example:

```
SELECT collation_name FROM information_schema.collations
  WHERE collation_name LIKE "%nopad%";
+------------------------------+
| collation_name               |
+------------------------------+
| big5_chinese_nopad_ci        |
| big5_nopad_bin               |
...
```

CHARACTER

Overview

This is a synonym for CHAR.

EXAMPLES

```
CREATE TABLE character_example (
  example CHARACTER
);
```

```
SHOW CREATE TABLE character_example\G
```

```
*************************** 1. row ***************************
       Table: character_example
Create Table: CREATE TABLE `character_example` (
  `example` char(1) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

This page is: Copyright © 2026 MariaDB. All rights reserved.

CHAR BYTE

Description

The `CHAR BYTE` data type is an alias for the BINARY data type. This is a compatibility feature.

EXAMPLES

```
CREATE TABLE char_byte_example (
  example CHAR BYTE
);
```

```
SHOW CREATE TABLE char_byte_example\G
```

```
*************************** 1. row ***************************
       Table: char_byte_example
Create Table: CREATE TABLE `char_byte_example` (
  `example` binary(1) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

CHAR VARYING

Overview

This is a synonym for VARCHAR.

EXAMPLES

```
CREATE TABLE char_varying_example (
  example CHAR VARYING(32)
);
```

```
SHOW CREATE TABLE char_varying_example\G
```

```
*************************** 1. row ***************************
       Table: char_varying_example
Create Table: CREATE TABLE `char_varying_example` (
  `example` varchar(32) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

This page is: Copyright © 2026 MariaDB. All rights reserved.

CLOB

Overview

This is a synonym for LONGTEXT.

EXAMPLES

```
SET sql_mode='oracle';

CREATE TABLE clob_example (
  example CLOB
);
```

```
SHOW CREATE TABLE clob_example\G
```

```
*************************** 1. row ***************************
       Table: clob_example
Create Table: CREATE TABLE "clob_example" (
  "example" longtext DEFAULT NULL
)
```

This page is: Copyright © 2026 MariaDB. All rights reserved.

ENUM

Syntax

```
ENUM('value1','value2',...) [CHARACTER SET charset_name] [COLLATE collation_name]
```

Description

An enumeration. A string object that can have only one value, chosen from the list of values 'value1', 'value2', …, `NULL` or the special '' error value. In theory, an `ENUM` column can have a maximum of 65,535 distinct values; in practice, the real maximum depends on many factors. `ENUM` values are represented internally as integers.

Trailing spaces are automatically stripped from `ENUM` values on table creation.

`ENUM` values require relatively little storage space compared to strings, either one or two bytes depending on the number of enumeration values.

NULL and empty values

An `ENUM` can also contain `NULL` and empty values. If the `ENUM` column is declared to permit `NULL` values, `NULL` becomes a valid value, as well as the default value (see below). If strict SQL Mode is not enabled, and an invalid value is inserted into an `ENUM`, a special empty string, with an index value of zero (see Numeric index, below), is inserted, with a warning. This may be confusing, because the empty string is also a possible value, and the only difference if that is this case its index is not 0. Inserting will fail with an error if strict mode is active.

If a `DEFAULT` clause is missing, the default value will be:

- `NULL` if the column is nullable;
- otherwise, the first value in the enumeration.

Numeric index

`ENUM` values are indexed numerically in the order they are defined, and sorting will be performed in this numeric order. We suggest not using `ENUM` to store numerals, as there is little to no storage space benefit, and it is easy to

confuse the enum integer with the enum numeral value by leaving out the quotes.

An `ENUM` defined as `ENUM('apple','orange','pear')` would have the following index values:

Index	Value
NULL	NULL
0	''
1	'apple'
2	'orange'
3	'pear'

Examples

```
CREATE TABLE fruits (
  id INT NOT NULL auto_increment PRIMARY KEY,
  fruit ENUM('apple','orange','pear'),
  bushels INT);

DESCRIBE fruits;
+---------+-------------------------------+------+-----+---------+----------------+
| Field   | Type                          | Null | Key | Default | Extra          |
+---------+-------------------------------+------+-----+---------+----------------+
| id      | int(11)                       | NO   | PRI | NULL    | auto_increment |
| fruit   | enum('apple','orange','pear') | YES  |     | NULL    |                |
| bushels | int(11)                       | YES  |     | NULL    |                |
+---------+-------------------------------+------+-----+---------+----------------+

INSERT INTO fruits
    (fruit,bushels) VALUES
    ('pear',20),
    ('apple',100),
    ('orange',25);

INSERT INTO fruits
    (fruit,bushels) VALUES
    ('avocado',10);
ERROR 1265 (01000): Data truncated for column 'fruit' at row 1

SELECT * FROM fruits;
+----+--------+---------+
| id | fruit  | bushels |
+----+--------+---------+
|  1 | pear   |      20 |
|  2 | apple  |     100 |
|  3 | orange |      25 |
+----+--------+---------+
```

Selecting by numeric index:

```
SELECT * FROM fruits WHERE fruit=2;
+----+--------+---------+
| id | fruit  | bushels |
+----+--------+---------+
|  3 | orange |      25 |
+----+--------+---------+
```

Sorting is according to the index value:

```
CREATE TABLE enums (a ENUM('2','1'));

INSERT INTO enums VALUES ('1'),('2');

SELECT * FROM enums ORDER BY a ASC;
+------+
| a    |
+------+
| 2    |
| 1    |
+------+
```

It's easy to get confused between returning the enum integer with the stored value, so we don't suggest using `ENUM` to store numerals. The first example returns the 1st indexed field ('2' has an index value of 1, as it's defined first), while the second example returns the string value '1'.

```
SELECT * FROM enums WHERE a=1;
+------+
| a    |
+------+
| 2    |
+------+

SELECT * FROM enums WHERE a='1';
+------+
| a    |
+------+
| 1    |
+------+
```

Example of `ENUM`:

```
CREATE TABLE enum_example (
  description VARCHAR(20),
  example ENUM('Alpha', 'Beta', 'Gamma', 'RC', 'Stable')
);
```

```
INSERT INTO enum_example VALUES
  ('foo', 'Beta'),
  ('bar', 'RC'),
  ('baz', 'Alpha'),
  ('bob', 5);
```

```
SELECT * FROM enum_example;

+-------------+---------+
| description | example |
+-------------+---------+
| foo         | Beta    |
| bar         | RC      |
| baz         | Alpha   |
| bob         | Stable  |
+-------------+---------+
```

INET4

> **Note:**
>
> INET4 is available from MariaDB 10.10.

Syntax

```
INET4
```

Description

`INET4` is a data type to store IPv4 addresses, as 4-byte binary strings.

> **CURRENT**
>
> Casting from INET4 data types to `INET6` is permitted, allowing for example comparisons between the two data types, and for `INET4` values to be inserted into `INET6` columns.
>
> **< 11.3**
>
> Casting from INET4 data types to `INET6` is **not** permitted.

Examples

```
CREATE OR REPLACE TABLE t1 (a INET4);

INSERT INTO t1 VALUES('0.0.0.0'), ('255.10.0.0'), ('255.255.255.255');

INSERT INTO t1 VALUES (0xa0000001);
INSERT INTO t1 VALUES (0xf0000000);
INSERT INTO t1 VALUES (0xff000001);

SELECT HEX(a), a FROM t1 ORDER BY a;
+----------+-----------------+
| HEX(a)   | a               |
+----------+-----------------+
| 00000000 | 0.0.0.0         |
| A0000001 | 160.0.0.1       |
| F0000000 | 240.0.0.0       |
| FF000001 | 255.0.0.1       |
| FF0A0000 | 255.10.0.0      |
| FFFFFFFF | 255.255.255.255 |
+----------+-----------------+
```

Casting from `INET4` to INET6 is permitted, allowing direct inserts.

> **CURRENT**
>
> ```
> CREATE TABLE t1 (a INET6);
>
> INSERT INTO t1 VALUES('0.0.0.0'), ('255.10.0.0'), ('255.255.255.255');
> Query OK, 3 rows affected (0.027 sec)
> ```
>
> Comparisons are also permitted:

```
CREATE OR REPLACE TABLE t1 (i4 INET4, i6 INET6);
INSERT INTO t1 VALUES('10.10.10.10','::ffff:192.168.0.1');

SELECT LEAST(i4,i6) FROM t1;
+--------------------+
| LEAST(i4,i6)       |
+--------------------+
| ::ffff:10.10.10.10 |
+--------------------+
```

< 11.3

```
CREATE TABLE t1 (a INET6);

INSERT INTO t1 VALUES('0.0.0.0'), ('255.10.0.0'), ('255.255.255.255');
ERROR 1292 (22007): Incorrect inet6 value: '0.0.0.0' for column `test`.`t1`.`a` at row 1
```

This page is licensed: CC BY-SA / Gnu FDL

INET6

> **Note:**
>
> `INET6` is available from MariaDB 10.5.

Syntax

```
INET6
```

Description

The `INET6` data type is intended for storage of IPv6 addresses, as well as IPv4 addresses assuming conventional mapping of IPv4 addresses into IPv6 addresses.

Both short and long IPv6 notation are permitted, according to RFC-5952.

- Values are stored as a 16-byte fixed length binary string, with most significant byte first.
- Storage engines see `INET6` as `BINARY(16)`.
- Clients see `INET6` as `CHAR(39)` and get text representation on retrieval.

The IPv4-compatible notation is considered as deprecated. It is supported for compatibility with the INET6_ATON function, which also understands this format. It's recommended to use the mapped format to store IPv4 addresses in `INET6`.

When an IPv4 mapped (or compatible) value is stored in `INET6`, it still occupies 16 bytes:

Retrieval

On retrieval, in the client-server text protocol, `INET6` values are converted to the short text representation, according to RFC-5952, that is with all leading zeroes in each group removed and with consequent zero groups compressed.

Besides creating one's own stored function, there is no a way to retrieve an `INET6` value using long text representation.

Casting

- CAST from a character string to `INET6` understands addresses in short or long text notation (including IPv4 mapped and compatible addresses). `NULL` is returned if the format is not understood.
- `CAST` from a binary string to `INET6` requires a 16-byte string as an argument. `NULL` is returned if the argument length is not equal to 16.
- `CAST` from other data types to `INET6` first converts data to a character string, then `CAST` from character string to `INET6` is applied.
- `CAST` from `INET6` to CHAR returns short text address notation.
- `CAST` from `INET6` to BINARY returns its 16-byte binary string representation.
- `CAST` from `INET6` to data types other than CHAR (e.g. `SIGNED`, `UNSIGNED`, `TIME`, etc) returns an error.

Comparisons

An `INET6` expression can be compared to:

- another `INET6` expression
- a character string expression with a text (short or long) address representation:
- a 16-byte binary string expression.

> **Warning:**
>
> Attempting to compare `INET6` to an expression of any other data type returns an error.

Mixing INET6 Values for Result

An `INET6` expression can be mixed for result (i.e. UNION, CASE..THEN, COALESCE etc) with:

- another `INET6` expression. The resulting data type is `INET6`.
- a character string in text (short or long) address representation. The result data type is `INET6`. The character string counterpart is automatically converted to `INET6`. If the string format is not understood, it's converted with a warning to either `NULL` or to '::', depending on the `NULL`-ability of the result.
- a 16-byte binary string. The resulting data type is `INET6`. The binary string counterpart is automatically converted to `INET6`. If the length of the binary string is not equal to 16, it's converted with a warning to `NULL` or to '::' depending on the `NULL`-ability of the result.

Attempts to mix `INET6` for result with other data types will return an error.

Mixing `INET6` with other data types for LEAST and GREATEST, when mixing for comparison and mixing for result are involved at the same time, uses the same rules with mixing for result, described in the previous paragraphs.

Functions and Operators

- HEX() with an INET6 argument returns a hexadecimal representation of the underlying 16-byte binary string
- Arithmetic operators (+,-,*,/,MOD,DIV) are not supported for INET6. This may change in the future.
- The INET6_ATON function now understands INET6 values as an argument
- The prototypes of the IS_IPV4_COMPAT and I S_IPV4_MAPPED functions have changed from `a BINARY(16)` to `a INET6`,

> **CURRENT**
>
> When the argument for the aforementioned two functions is not `INET6`, automatic implicit `CAST` to `INET6` is applied. As a consequence, both functions understand arguments in both text representation and binary(16) representation.

> **< 10.5**
>
> When the argument for the aforementioned two functions is not `INET6`, automatic implicit `CAST` to `INET6` is **not** applied.

Prepared Statement Parameters

INET6 understands both text and binary(16) address representation in prepared statement parameters (PREPARE..EXECUTE and EXECUTE IMMEDIATE statements).

Migration between BINARY(16) and INET6

> **CURRENT**
>
> You may have used BINARY(16) as a storage for IPv6 internet addresses, in combination with INET6_ATON and INET6_NTOA to respectively insert and retrieve data.
>
> However, you can ALTER `BINARY(16)` columns storing IPv6 addresses to `INET6`. After such an alter, there is no a need to use `INET6_ATON()` and `INET6_NTOA()`. Addresses can be inserted and retrieved directly.
>
> **< 10.5**
>
> You may use BINARY(16) as a storage for IPv6 internet addresses, in combination with INET6_ATON and INET6_NTOA to respectively insert and retrieve data.

It is also possible to convert `INET6` columns to `BINARY(16)` and continue using the data in combination with `INET6_NTOA()` and `INET6_ATON()`.

Examples

```
CREATE TABLE t1 (a INET6);
```

Inserting using short text address notation:

```
INSERT INTO t1 VALUES ('2001:db8::ff00:42:8329');
```

Long text address notation:

```
INSERT INTO t1 VALUES ('2001:0db8:0000:0000:0000:ff00:0042:8329');
```

16-byte binary string notation:

```
INSERT INTO t1 VALUES (0x20010DB8000000000000FF0000428329);
INSERT INTO t1 VALUES (UNHEX('20010DB8000000000000FF0000428329'));
```

IPv4 addresses, using IPv4-mapped and IPv4-compatible notations:

```
INSERT INTO t1 VALUES ('::ffff:192.0.2.128'); -- mapped
INSERT INTO t1 VALUES ('::192.0.2.128'); -- compatible
```

```
SELECT * FROM t1;
+------------------------+
| a                      |
+------------------------+
| 2001:db8::ff00:42:8329 |
| 2001:db8::ff00:42:8329 |
| 2001:db8::ff00:42:8329 |
| 2001:db8::ff00:42:8329 |
| ::ffff:192.0.2.128     |
| ::192.0.2.128          |
+------------------------+
```

IPv4 mapped (or compatible) values still occupy 16 bytes:

```
CREATE OR REPLACE TABLE t1 (a INET6);

INSERT INTO t1 VALUES ('::ffff:192.0.2.128');

SELECT * FROM t1;
+--------------------+
| a                  |
+--------------------+
| ::ffff:192.0.2.128 |
+--------------------+

SELECT HEX(a) FROM t1;
+----------------------------------+
| HEX(a)                           |
+----------------------------------+
| 00000000000000000000FFFFC0000280 |
+----------------------------------+
```

Casting from `INET6` to anything other than CHAR returns an error:

```
SELECT CAST(a AS DECIMAL) FROM t1;

ERROR 4079 (HY000): Illegal parameter data type inet6 for operation 'decimal_typecast'
```

Comparison Examples

Comparison with another `INET6` expression:

```
CREATE OR REPLACE TABLE t1 (a INET6);
    CREATE OR REPLACE TABLE t2 (a INET6);

    INSERT INTO t1 VALUES ('2001:db8::ff00:42:8328'),('2001:db8::ff00:42:8329');
    INSERT INTO t2 VALUES ('2001:db8::ff00:42:832a'),('2001:db8::ff00:42:8329');

    SELECT t1.* FROM t1,t2 WHERE t1.a=t2.a;
    +------------------------+
    | a                      |
    +------------------------+
    | 2001:db8::ff00:42:8329 |
    +------------------------+
```

With a character string expression with a text (short or long) address representation:

```
CREATE OR REPLACE TABLE t1 (a INET6);

    INSERT INTO t1 VALUES ('2001:db8::ff00:42:8329');

    SELECT * FROM t1 WHERE a='2001:db8::ff00:42:8329';
    +------------------------+
    | a                      |
    +------------------------+
    | 2001:db8::ff00:42:8329 |
    +------------------------+
```

With a 16-byte binary string expression:

```
CREATE OR REPLACE TABLE t1 (a INET6);

    INSERT INTO t1 VALUES ('2001:db8::ff00:42:8329');

    SELECT * FROM t1 WHERE a=X'20010DB8000000000000FF0000428329';
    +------------------------+
    | a                      |
    +------------------------+
    | 2001:db8::ff00:42:8329 |
    +------------------------+
```

With an expression of another data type:

```
SELECT * FROM t1 WHERE a=1;
ERROR 4078 (HY000): Illegal parameter data types inet6 and int for operation '='
```

Mixing for Result Examples

Mixed with another `INET6` expression, returning an `INET6` data type:

```
CREATE OR REPLACE TABLE t1 (a INET6, b INET6);

    INSERT INTO t1 VALUES (NULL,'2001:db8::ff00:42:8329');

    SELECT a FROM t1 UNION SELECT b FROM t1;
    +------------------------+
    | a                      |
    +------------------------+
    | NULL                   |
    | 2001:db8::ff00:42:8329 |
    +------------------------+

    SELECT COALESCE(a, b) FROM t1;
    +------------------------+
    | COALESCE(a, b)         |
    +------------------------+
    | 2001:db8::ff00:42:8329 |
    +------------------------+
```

Mixed with a character string in text (short or long) address representation:

```
CREATE OR REPLACE TABLE t1 (a INET6, b VARCHAR(64));

    INSERT INTO t1 VALUES (NULL,'2001:db8::ff00:42:8328');

    INSERT INTO t1 VALUES (NULL,'2001:db8::ff00:42:832a garbage');

    SELECT COALESCE(a,b) FROM t1;
    +------------------------+
    | COALESCE(a,b)          |
    +------------------------+
    | 2001:db8::ff00:42:8328 |
    | NULL                   |
    +------------------------+
    2 rows in set, 1 warning (0.001 sec)

    SHOW WARNINGS;
    +---------+------+-------------------------------------------------------------+
    | Level   | Code | Message                                                     |
    +---------+------+-------------------------------------------------------------+
    | Warning | 1292 | Incorrect inet6 value: '2001:db8::ff00:42:832a garbage' |
    +---------+------+-------------------------------------------------------------+
```

Mixed with a 16-byte binary string:

```
CREATE OR REPLACE TABLE t1 (a INET6, b VARBINARY(16));

    INSERT INTO t1 VALUES (NULL,CONCAT(0xFFFF,REPEAT(0x0000,6),0xFFFF));

    INSERT INTO t1 VALUES (NULL,0x00/*garbage*/);

    SELECT COALESCE(a,b) FROM t1;
    +---------------+
    | COALESCE(a,b) |
    +---------------+
    | ffff::ffff    |
    | NULL          |
    +---------------+
    2 rows in set, 1 warning (0.001 sec)

    SHOW WARNINGS;
    +---------+------+------------------------------+
    | Level   | Code | Message                      |
    +---------+------+------------------------------+
    | Warning | 1292 | Incorrect inet6 value: '\x00' |
    +---------+------+------------------------------+
```

Mixing with other data types:

```
SELECT CAST('ffff::ffff' AS INET6) UNION SELECT 1;
ERROR 4078 (HY000): Illegal parameter data types inet6 and int for operation 'UNION'
```

Functions and Operators Examples

HEX with an `INET6` argument returning a hexadecimal representation:

```
SELECT HEX(CAST('2001:db8::ff00:42:8329' AS INET6));
    +---------------------------------------------+
    | HEX(CAST('2001:db8::ff00:42:8329' AS INET6)) |
    +---------------------------------------------+
    | 20010DB8000000000000FF0000428329             |
    +---------------------------------------------+
```

INET6_ATON now understands `INET6` values as an argument:

```
CREATE OR REPLACE TABLE t1 (a INET6);

    INSERT INTO t1 VALUES ('2001:db8::ff00:42:8329');

    SELECT a, HEX(INET6_ATON(a)) FROM t1;
    +-----------------------+----------------------------------+
    | a                     | HEX(INET6_ATON(a))               |
    +-----------------------+----------------------------------+
    | 2001:db8::ff00:42:8329 | 20010DB8000000000000FF0000428329 |
    +-----------------------+----------------------------------+
```

IS_IPV4_COMPAT and IS_IPV4_MAPPED prototype now `a BINARY(16))`:

```
CREATE OR REPLACE TABLE t1 (a INET6);

    INSERT INTO t1 VALUES ('2001:db8::ff00:42:8329');
    INSERT INTO t1 VALUES ('::ffff:192.168.0.1');
    INSERT INTO t1 VALUES ('::192.168.0.1');

    SELECT a, IS_IPV4_MAPPED(a), IS_IPV4_COMPAT(a) FROM t1;
    +-----------------------+------------------+------------------+
    | a                     | IS_IPV4_MAPPED(a) | IS_IPV4_COMPAT(a) |
    +-----------------------+------------------+------------------+
    | 2001:db8::ff00:42:8329 |                0 |                0 |
    | ::ffff:192.168.0.1     |                1 |                0 |
    | ::192.168.0.1          |                0 |                1 |
    +-----------------------+------------------+------------------+
```

Automatic implicit `CAST` to `INET6`:

```
CREATE OR REPLACE TABLE t1 (
      a INET6,
      b VARCHAR(39) DEFAULT a
    );

    INSERT INTO t1 (a) VALUES ('ffff::ffff'),('::ffff:192.168.0.1');

    SELECT a, IS_IPV4_MAPPED(a), b, IS_IPV4_MAPPED(b) FROM t1;
    +-------------------+------------------+-------------------+------------------+
    | a                 | IS_IPV4_MAPPED(a) | b                 | IS_IPV4_MAPPED(b) |
    +-------------------+------------------+-------------------+------------------+
    | ffff::ffff        |                0 | ffff::ffff        |                0 |
    | ::ffff:192.168.0.1 |                1 | ::ffff:192.168.0.1 |                1 |
    +-------------------+------------------+-------------------+------------------+

    CREATE OR REPLACE TABLE t1 (
      a INET6,
      b BINARY(16) DEFAULT UNHEX(HEX(a))
    );

    INSERT INTO t1 (a) VALUES ('ffff::ffff'),('::ffff:192.168.0.1');

    SELECT a, IS_IPV4_MAPPED(a), HEX(b), IS_IPV4_MAPPED(b) FROM t1;
    +-------------------+------------------+----------------------------------+------------------+
    | a                 | IS_IPV4_MAPPED(a) | HEX(b)                           | IS_IPV4_MAPPED(b) |
    +-------------------+------------------+----------------------------------+------------------+
    | ffff::ffff        |                0 | FFFF00000000000000000000FFFF |                0 |
    | ::ffff:192.168.0.1 |                1 | 00000000000000000000FFFFC0A80001 |                1 |
    +-------------------+------------------+----------------------------------+------------------+
```

Prepared Statement Parameters Examples

```
CREATE OR REPLACE TABLE t1 (a INET6);

EXECUTE IMMEDIATE 'INSERT INTO t1 VALUES (?)' USING 'ffff::fffe';
EXECUTE IMMEDIATE 'INSERT INTO t1 VALUES (?)' USING X'FFFF00000000000000000000FFFF';

SELECT * FROM t1;
+------------+
| a          |
+------------+
| ffff::fffe |
| ffff::ffff |
+------------+

EXECUTE IMMEDIATE 'SELECT * FROM t1 WHERE a=?' USING 'ffff::fffe';
+------------+
| a          |
+------------+
| ffff::fffe |
+------------+

EXECUTE IMMEDIATE 'SELECT * FROM t1 WHERE a=?' USING X'FFFF00000000000000000000FFFF';
+------------+
| a          |
+------------+
| ffff::ffff |
+------------+
```

Migration between BINARY(16) and INET6 Examples

CURRENT

```
CREATE OR REPLACE TABLE t1 (a BINARY(16));

INSERT INTO t1 VALUES (INET6_ATON('ffff::ffff'));

SELECT INET6_NTOA(a) FROM t1;
+---------------+
| INET6_NTOA(a) |
+---------------+
| ffff::ffff    |
+---------------+
```

Migrating to `INET6`:

```
ALTER TABLE t1 MODIFY a INET6;

INSERT INTO t1 VALUES ('ffff::fffe');

SELECT * FROM t1;
+------------+
| a          |
+------------+
| ffff::ffff |
| ffff::fffe |
+------------+
```

< 10.5

There's no conversion you can use:

```
CREATE OR REPLACE TABLE t1 (a BINARY(16));

INSERT INTO t1 VALUES (INET6_ATON('ffff::ffff'));

SELECT INET6_NTOA(a) FROM t1;
+---------------+
| INET6_NTOA(a) |
+---------------+
| ffff::ffff    |
+---------------+
```

Migration from `INET6` to `BINARY(16)`:

```
CREATE OR REPLACE TABLE t1 (a INET6);

INSERT INTO t1 VALUES ('2001:db8::ff00:42:8329');
INSERT INTO t1 VALUES ('::ffff:192.168.0.1');
INSERT INTO t1 VALUES ('::192.168.0.1');

ALTER TABLE t1 MODIFY a BINARY(16);

SELECT INET6_NTOA(a) FROM t1;
+------------------------+
| INET6_NTOA(a)          |
+------------------------+
| 2001:db8::ff00:42:8329 |
| ::ffff:192.168.0.1     |
| ::192.168.0.1          |
+------------------------+
```

Casting from INET4 to INET6

CURRENT

Casting from INET4 data types to `INET6` is permitted, allowing `INET4` values to be inserted into `INET6` columns.

```
CREATE TABLE t1 (a INET6);

INSERT INTO t1 VALUES('0.0.0.0'), ('255.10.0.0'), ('255.255.255.255');
Query OK, 3 rows affected (0.027 sec)
```

< 11.3

Casting from INET4 data types to `INET6` is **not** permitted. You get an error if you try:

```
CREATE TABLE t1 (a INET6);

INSERT INTO t1 VALUES('0.0.0.0'), ('255.10.0.0'), ('255.255.255.255');
ERROR 1292 (22007): Incorrect inet6 value: '0.0.0.0' for column `test`.`t1`.`a` at row 1
```

JSON Data Type

The `JSON` alias was added to make it possible to use JSON columns in statement based replication from MySQL to MariaDB and to make it possible for MariaDB to read mysqldumps from MySQL.

`JSON` is an alias for `LONGTEXT COLLATE utf8mb4_bin` introduced for compatibility reasons with MySQL's JSON data type. MariaDB implements this as a LONGTEXT rather, as the JSON data type contradicts the SQL:2016 standard, and MariaDB's benchmarks indicate that performance is at least equivalent.

In order to ensure that a valid json document is inserted, the JSON_VALID function can be used as a CHECK constraint. This constraint is automatically included for types using the `JSON` alias.

The assigned text value is retained verbatim. If a value fails `JSON_VALID()`, an error is raised. This `CHECK` constraint can also be manually added to any `LONGTEXT` field. When a JSON object contains duplicate keys, only the first key-value pair is accessible via functions like `JSON_EXTRACT()`.

Examples

```
CREATE TABLE t (j JSON);

DESC t;
+-------+----------+------+-----+---------+-------+
| Field | Type     | Null | Key | Default | Extra |
+-------+----------+------+-----+---------+-------+
| j     | longtext | YES  |     | NULL    |       |
+-------+----------+------+-----+---------+-------+
```

With validation:

```
CREATE TABLE t2 (
  j JSON
  CHECK (JSON_VALID(j))
);

INSERT INTO t2 VALUES ('invalid');
ERROR 4025 (23000): CONSTRAINT `j` failed for `test`.`t2`

INSERT INTO t2 VALUES ('{"id": 1, "name": "Monty"}');
Query OK, 1 row affected (0.13 sec)
```

JSON example:

```
CREATE TABLE json_example (
  description VARCHAR(20),
  example JSON
);
```

```
SHOW CREATE TABLE json_example\G
```

```
*************************** 1. row ***************************
       Table: json_example
Create Table: CREATE TABLE `json_example` (
  `description` varchar(20) DEFAULT NULL,
  `example` longtext CHARACTER SET utf8mb4 COLLATE utf8mb4_bin DEFAULT NULL CHECK (json_valid(`example`))
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

```
INSERT INTO json_example VALUES
  ('Array', '[ 1, 2, 3 ]'),
  ('Dictionary', '{ "a": 1, "b": 2 }'),
  ('Duplicates', '{ "a":1,"b":2, "a":3,"b": 4,"b":5}');
```

```
SELECT * FROM json_example;
```

```
+-------------+-----------------------------------+
| description | example                           |
+-------------+-----------------------------------+
| Array       | [ 1, 2, 3 ]                       |
| Dictionary  | { "a": 1, "b": 2 }                |
| Duplicates  | { "a":1,"b":2, "a":3,"b": 4,"b":5} |
+-------------+-----------------------------------+
```

```
SELECT description, JSON_EXTRACT(example, '$.b')
FROM json_example;
```

```
+-------------+-----------------------------+
| description | JSON_EXTRACT(example, '$.b') |
+-------------+-----------------------------+
| Array       | NULL                        |
| Dictionary  | 2                           |
| Duplicates  | 2                           |
+-------------+-----------------------------+
```

```
INSERT INTO json_example VALUES
  ('Invalid', '{');
```

```
ERROR 4025 (23000): CONSTRAINT `json_example.example` failed for `test`.`json_example`
```

Replicating JSON Data Between MySQL and MariaDB

The `JSON` type in MySQL stores the JSON object in a compact form, not as LONGTEXT as in MariaDB.
This means that row-based replication will not work for `JSON` types from MySQL to MariaDB.

There are a few different ways to solve this:

- Use statement-based replication.
- Change the `JSON` column to type `TEXT` in MySQL.
- If you must use row-based replication and cannot change the MySQL master from `JSON` to `TEXT`, you can try to introduce an intermediate MySQL replica, and change the column type from `JSON` to `TEXT` on it. Then you replicate from this intermediate slave to MariaDB.

Converting a MySQL TABLE with JSON Fields to MariaDB

MariaDB can't directly access MySQL's `JSON` format.

There are a few different ways to move the table to MariaDB:

- From MariaDB 10.5.7, you can use the mysql_json plugin. See Making MariaDB understand MySQL JSON (blog post).
- Change the JSON column to type `TEXT` in MySQL. After this, MariaDB can directly use the table without any need for a dump and restore.
- Use mysqldump to copy the table.

Differences Between MySQL JSON Strings and MariaDB JSON Strings

- In MySQL, JSON is an object and is compared according to json values. In MariaDB JSON strings are normal strings and compared as strings. One exception is when using JSON_EXTRACT() in which case strings are unescaped before comparison.

LONG and LONG VARCHAR

`LONG` and `LONG VARCHAR` are synonyms for MEDIUMTEXT.

```
CREATE TABLE t1 (a LONG, b LONG VARCHAR);

DESC t1;
+-------+------------+------+-----+---------+-------+
| Field | Type       | Null | Key | Default | Extra |
+-------+------------+------+-----+---------+-------+
| a     | mediumtext | YES  |     | NULL    |       |
| b     | mediumtext | YES  |     | NULL    |       |
+-------+------------+------+-----+---------+-------+
```

This page is licensed: CC BY-SA / Gnu FDL

LONG CHAR VARYING

Overview

See MEDIUMTEXT.

EXAMPLES

```
CREATE TABLE long_char_varying_example (
  example LONG CHAR VARYING
);
```

```
SHOW CREATE TABLE long_char_varying_example\G
```

```
*************************** 1. row ***************************
       Table: long_char_varying_example
Create Table: CREATE TABLE `long_char_varying_example` (
  `example` mediumtext DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

This page is: Copyright © 2026 MariaDB. All rights reserved.

LONG CHARACTER VARYING

Overview

See MEDIUMTEXT.

EXAMPLES

```
CREATE TABLE long_character_varying_example (
  example LONG CHARACTER VARYING
);
```

```
SHOW CREATE TABLE long_character_varying_example\G
```

```
*************************** 1. row ***************************
       Table: long_character_varying_example
Create Table: CREATE TABLE `long_character_varying_example` (
  `example` mediumtext DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

This page is: Copyright © 2026 MariaDB. All rights reserved.

LONG VARBINARY

Overview

See MEDIUMBLOB.

EXAMPLES

```
CREATE TABLE long_varbinary_example (
  example LONG VARBINARY
);
```

```
SHOW CREATE TABLE long_varbinary_example\G
```

```
*************************** 1. row ***************************
       Table: long_varbinary_example
Create Table: CREATE TABLE `long_varbinary_example` (
  `example` mediumblob DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

This page is: Copyright © 2026 MariaDB. All rights reserved.

LONG VARCHAR

Overview

See MEDIUMTEXT.

EXAMPLES

```
CREATE TABLE long_varchar_example (
  example LONG VARCHAR
);
```

```
SHOW CREATE TABLE long_varchar_example\G
```

```
*************************** 1. row ***************************
       Table: long_varchar_example
Create Table: CREATE TABLE `long_varchar_example` (
  `example` mediumtext DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

This page is: Copyright © 2026 MariaDB. All rights reserved.

LONG VARCHARACTER

Overview

See MEDIUMTEXT.

EXAMPLES

```
CREATE TABLE long_varcharacter_example (
  example LONG VARCHARACTER
);
```

```
SHOW CREATE TABLE long_varcharacter_example\G
```

```
*************************** 1. row ***************************
       Table: long_varcharacter_example
Create Table: CREATE TABLE `long_varcharacter_example` (
  `example` mediumtext DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

This page is: Copyright © 2026 MariaDB. All rights reserved.

LONGBLOB

Syntax

```
LONGBLOB
```

Description

A BLOB column with a maximum length of 4,294,967,295 bytes (2^{32} - 1), or 4GB. The effective maximum length of `LONGBLOB` columns depends on the configured maximum packet size in the client/server protocol and available memory. Each `LONGBLOB` value is stored using a four-byte length prefix that indicates the number of bytes in the value.

Oracle Mode

In Oracle mode, `BLOB` is a synonym for `LONGBLOB`.

Examples

```
CREATE TABLE longblob_example (
   description VARCHAR(20),
   example LONGBLOB
) DEFAULT CHARSET=latin1; -- One byte per char makes the examples clearer
```

Note that the maximum size of a `LONGBLOB` is so large that it cannot be sent to the server without breaking the value up into chunks (something that the command-line client cannot do). For values larger than 16M you can increase the max_allowed_packet size up to a maximum of 1024M to increase the allowed size of non-chunked values.

```
INSERT INTO longblob_example VALUES
   ('Normal foo', 'foo'),
   ('Trailing spaces foo', 'foo      '),
   ('NULLed', NULL),
   ('Empty', ''),
   ('Maximum', RPAD('', 4294967295, CHAR(7)));
```

```
ERROR 1301 (HY000): Result of rpad() was larger than max_allowed_packet (16777216) - truncated
```

Data Too Long

When `SQL_MODE` is strict (the default) a value is considered “too long” when its length exceeds the size of the data type, and an error is generated.

Example of data too long behavior for `LONGBLOB`:

```
TRUNCATE longblob_example;

INSERT INTO longblob_example VALUES
   ('Overflow', RPAD('', 4294967296, CHAR(7)));
```

```
ERROR 1301 (HY000): Result of rpad() was larger than max_allowed_packet (16777216) - truncated
```

See Also

- BLOB and TEXT Data Types
- Data Type Storage Requirements
- Oracle mode

This page is licensed: GPLv2, originally from fill_help_tables.sql

LONGTEXT

Syntax

```
LONGTEXT [CHARACTER SET charset_name] [COLLATE collation_name]
```

Description

A TEXT column with a maximum length of 4,294,967,295 or 4GB (2^{32} - 1) characters. The effective maximum length is less if the value contains multi-byte characters. The effective maximum length of `LONGTEXT` columns also depends on the configured maximum packet size in the client/server protocol and available memory. Each `LONGTEXT` value is stored using a four-byte length prefix that indicates the number of bytes in the value.

`JSON` is an alias for `LONGTEXT`. See JSON Data Type for details.

Oracle Mode

In Oracle mode, CLOB is a synonym for `LONGTEXT`.

EXAMPLES

LONGTEXT

Example of `LONGTEXT`:

```
CREATE TABLE longtext_example (
   description VARCHAR(20),
   example LONGTEXT
) DEFAULT CHARSET=latin1; -- One byte per char makes the examples clearer
```

Warning:

The maximum size of a `LONGTEXT` is so large that it cannot be sent to the server without breaking the value up into chunks (something that the command-line client cannot do). For values larger than `16M`, you can increase the `max_allowed_packet` size up to a maximum of `1024M` to increase the allowed size of non-chunked values.

```
INSERT INTO longtext_example VALUES
   ('Normal foo', 'foo'),
   ('Trailing spaces foo', 'foo      '),
   ('NULLed', NULL),
   ('Empty', ''),
   ('Maximum', RPAD('', 4294967295, 'x'));
```

```
ERROR 1301 (HY000): Result of rpad() was larger than max_allowed_packet (16777216) - truncated
```

Data Too Long

When `SQL_MODE` is strict (the default) a value is considered "too long" when its length exceeds the size of the data type, and an error is generated.

Example of data too long behavior for `LONGTEXT`:

```
TRUNCATE longtext_example;

INSERT INTO longtext_example VALUES
   ('Overflow', RPAD('', 4294967296, 'x'));
```

```
ERROR 1301 (HY000): Result of rpad() was larger than max_allowed_packet (16777216) - truncated
```

See Also

- TEXT
- BLOB and TEXT Data Types
- Data Type Storage Requirements
- JSON Data Type
- Oracle mode

This page is licensed: GPLv2, originally from fill_help_tables.sql

MEDIUMBLOB

Syntax

```
MEDIUMBLOB
```

Description

A BLOB column with a maximum length of 16,777,215 (2^{24} - 1) bytes. Each `MEDIUMBLOB` value is stored using a three-byte length prefix that indicates the number of bytes in the value.

`LONG VARBINARY` is a synonym for `MEDIUMBLOB`.

EXAMPLES

MEDIUMBLOB

Example of `MEDIUMBLOB`:

```
CREATE TABLE mediumblob_example (
   description VARCHAR(20),
   example MEDIUMBLOB
) DEFAULT CHARSET=latin1; -- One byte per char makes the examples clearer
```

```
INSERT INTO mediumblob_example VALUES
   ('Normal foo', 'foo'),
   ('Trailing spaces foo', 'foo      '),
   ('NULLed', NULL),
   ('Empty', ''),
   ('Maximum', RPAD('', 16777215, CHAR(7)));
```

```
SELECT description, LENGTH(example) AS length
   FROM mediumblob_example;
```

```
+--------------------+----------+
| description        | length   |
+--------------------+----------+
| Normal foo         |        3 |
| Trailing spaces foo |        9 |
| NULLed             |     NULL |
| Empty              |        0 |
| Maximum            | 16777215 |
+--------------------+----------+
```

Data Too Long

When `SQL_MODE` is strict (the default), a value is considered "too long" when its length exceeds the size of the data type, and an error is generated.

Example of data too long behavior for `MEDIUMBLOB`:

```
TRUNCATE mediumblob_example;
```

```
INSERT INTO mediumblob_example VALUES
   ('Overflow', RPAD('', 16777216, CHAR(7)));
```

```
ERROR 1406 (22001): Data too long for column 'example' at row 1
```

- Data Type Storage Requirements

This page is licensed: GPLv2, originally from fill_help_tables.sql

MEDIUMTEXT

Syntax

```
MEDIUMTEXT [CHARACTER SET charset_name] [COLLATE collation_name]
```

Description

A TEXT column with a maximum length of 16,777,215 (2^{24} - 1) characters. The effective maximum length is less if the value contains multi-byte characters. Each `MEDIUMTEXT` value is stored using a three-byte length prefix that indicates the number of bytes in the value.

SYNONYMS

The following are synonyms for `MEDIUMTEXT`:

- LONG
- LONG CHAR VARYING
- LONG CHARACTER VARYING
- LONG VARCHAR
- LONG VARCHARACTER

EXAMPLES

MEDIUMTEXT

Example of `MEDIUMTEXT`:

```
CREATE TABLE mediumtext_example (
   description VARCHAR(20),
   example MEDIUMTEXT
) DEFAULT CHARSET=latin1; -- One byte per char makes the examples clearer
```

```
INSERT INTO mediumtext_example VALUES
   ('Normal foo', 'foo'),
   ('Trailing spaces foo', 'foo      '),
   ('NULLed', NULL),
   ('Empty', ''),
   ('Maximum', RPAD('', 16777215, 'x'));
```

```
SELECT description, LENGTH(example) AS length
   FROM mediumtext_example;
```

```
+--------------------+----------+
| description        | length   |
+--------------------+----------+
| Normal foo         |        3 |
| Trailing spaces foo |        9 |
| NULLed             |     NULL |
| Empty              |        0 |
| Maximum            | 16777215 |
+--------------------+----------+
```

Data Too Long

When `SQL_MODE` is strict (the default) a value is considered “too long” when its length exceeds the size of the data type, and an error is generated.

Example of data too long behavior for `MEDIUMTEXT`:

```
TRUNCATE mediumtext_example;

INSERT INTO mediumtext_example VALUES
   ('Overflow', RPAD('', 16777216, 'x'));
```

```
ERROR 1406 (22001): Data too long for column 'example' at row 1
```

NATIONAL CHAR

Overview

Fixed-length string of specific character set with limit up to 255 bytes.

Examples

```
CREATE TABLE national_char_example (
  example NATIONAL CHAR(32)
);
```

```
SHOW CREATE TABLE national_char_example\G
```

```
*************************** 1. row ***************************
       Table: national_char_example
Create Table: CREATE TABLE `national_char_example` (
  `example` char(32) CHARACTER SET utf8mb3 DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

External References

  `example` char(32) CHARACTER SET utf8 DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

This page is: Copyright © 2026 MariaDB. All rights reserved.

NATIONAL VARCHAR

Overview

Variable-length string of specific character set with limit up to 65,535 bytes.

EXAMPLES

```
CREATE TABLE national_varchar_example (
  example NATIONAL VARCHAR(32)
);
```

```
SHOW CREATE TABLE national_varchar_example\G
```

```
*************************** 1. row ***************************
       Table: national_varchar_example
Create Table: CREATE TABLE `national_varchar_example` (

RAW

Overview

See VARBINARY.

EXAMPLES

```
SET sql_mode='oracle';
```

```
CREATE TABLE raw_example (
  example RAW(32)
);
```

```
SHOW CREATE TABLE raw_example\G
```

```
*************************** 1. row ***************************
       Table: raw_example
Create Table: CREATE TABLE "raw_example" (
  "example" varbinary(32) DEFAULT NULL
)
```

This page is: Copyright © 2026 MariaDB. All rights reserved.

ROW

Syntax

```
ROW (<field name> <data type> [{, <field name> <data type>}... ])
```

Description

`ROW` is a data type for stored procedure variables.

Features

ROW fields as normal variables

`ROW` fields (members) act as normal variables, and are able to appear in all query parts where a stored procedure variable is allowed:

- Assignment is using the `:=` operator and the SET command:

```
a.x:= 10;
a.x:= b.x;
SET a.x= 10, a.y=20, a.z= b.z;
```

- Passing to functions and operators:

```
SELECT f1(rec.a), rec.a<10;
```

- Clauses (select list, WHERE, HAVING, LIMIT, etc…,):

```
SELECT var.a, t1.b FROM t1 WHERE t1.b=var.b LIMIT var.c;
```

- `INSERT` values:

```
INSERT INTO t1 VALUES (rec.a, rec.b, rec.c);
```

- `SELECT .. INTO` targets:

```
SELECT a,b INTO rec.a, rec.b FROM t1 WHERE t1.id=10;
```

- Dynamic SQL out parameters (EXECUTE and EXECUTE IMMEDIATE)

```
EXECUTE IMMEDIATE 'CALL proc_with_out_param(?)' USING rec.a;
```

ROW type variables as FETCH targets

`ROW` type variables are allowed as FETCH targets:

```
FETCH cur INTO rec;
```

where `cur` is a `CURSOR` and `rec` is a `ROW` type stored procedure variable.

Note, currently an attempt to use `FETCH` for a `ROW` type variable returns this error:

```
ERROR 1328 (HY000): Incorrect number of FETCH variables
```

`FETCH` from a cursor `cur` into a `ROW` variable `rec` works as follows:

- The number of fields in `cur` must match the number of fields in `rec`. Otherwise, an error is reported.
- Assignment is done from left to right. The first cursor field is assigned to the first variable field, the second cursor field is assigned to the second variable field, etc.
- Field names in `rec` are not important and can differ from field names in `cur`.

See FETCH Examples (below) for examples of using this with `sql_mode=ORACLE` and `sql_mode=DEFAULT`.

ROW type variables as `SELECT...INTO` targets

`ROW` type variables are allowed as `SELECT..INTO` targets with some differences depending on which `sql_mode` is in use.

- When using `sql_mode=ORACLE`, `table%ROWTYPE` and `cursor%ROWTYPE` variables can be used as `SELECT...INTO` targets.
- Using multiple `ROW` variables in the `SELECT..INTO` list will report an error.
- Using `ROW` variables with a different column count than in the `SELECT..INTO` list will report an error.

See SELECT…INTO Examples (below) for examples of using this with `sql_mode=ORACLE` and `sql_mode=DEFAULT`.

Features not implemented

The following features are planned, but not implemented yet:

- Returning a `ROW` type expression from a stored function (see MDEV-12252). This will need some grammar change to support field names after parentheses:

```
SELECT f1().x FROM DUAL;
```

- Returning a `ROW` type expression from a built-in hybrid type function, such as `CASE`, `IF`, etc.
- `ROW` of `ROW` values

Examples

Declaring a ROW in a stored procedure

```
DELIMITER $$
CREATE PROCEDURE p1()
BEGIN
  DECLARE r ROW (c1 INT, c2 VARCHAR(10));
  SET r.c1= 10;
  SET r.c2= 'test';
  INSERT INTO t1 VALUES (r.c1, r.c2);
END;
$$
DELIMITER ;
CALL p1();
```

FETCH Examples

A complete `FETCH` example for `sql_mode=ORACLE`:

```
DROP TABLE IF EXISTS t1;
CREATE TABLE t1 (a INT, b VARCHAR(32));
INSERT INTO t1 VALUES (10,'b10');
INSERT INTO t1 VALUES (20,'b20');
INSERT INTO t1 VALUES (30,'b30');

SET sql_mode=oracle;
DROP PROCEDURE IF EXISTS p1;
DELIMITER $$
CREATE PROCEDURE p1 AS
  rec ROW(a INT, b VARCHAR(32));
  CURSOR c IS SELECT a,b FROM t1;
BEGIN
  OPEN c;
  LOOP
    FETCH c INTO rec;
    EXIT WHEN c%NOTFOUND;
    SELECT ('rec=(' || rec.a ||','|| rec.b||')');
  END LOOP;
  CLOSE c;
END;
$$
DELIMITER ;
CALL p1();
```

A complete `FETCH` example for `sql_mode=DEFAULT`:

```
DROP TABLE IF EXISTS t1;
CREATE TABLE t1 (a INT, b VARCHAR(32));
INSERT INTO t1 VALUES (10,'b10');
INSERT INTO t1 VALUES (20,'b20');
INSERT INTO t1 VALUES (30,'b30');

SET sql_mode=DEFAULT;
DROP PROCEDURE IF EXISTS p1;
DELIMITER $$
CREATE PROCEDURE p1()
BEGIN
  DECLARE done INT DEFAULT FALSE;
  DECLARE rec ROW(a INT, b VARCHAR(32));
  DECLARE c CURSOR FOR SELECT a,b FROM t1;
  DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = TRUE;
  OPEN c;
read_loop:
  LOOP
    FETCH c INTO rec;
    IF done THEN
      LEAVE read_loop;
    END IF;
    SELECT CONCAT('rec=(',rec.a,',',rec.b,')');
  END LOOP;
  CLOSE c;
END;
$$
DELIMITER ;
CALL p1();
```

SELECT…INTO Examples

A `SELECT...INTO` example for `sql_mode=DEFAULT`:

```
SET sql_mode=DEFAULT;
DROP TABLE IF EXISTS t1;
DROP PROCEDURE IF EXISTS p1;
CREATE TABLE t1 (a INT, b VARCHAR(32));
INSERT INTO t1 VALUES (10,'b10');
DELIMITER $$
CREATE PROCEDURE p1()
BEGIN
  DECLARE rec1 ROW(a INT, b VARCHAR(32));
  SELECT * FROM t1 INTO rec1;
  SELECT rec1.a, rec1.b;
END;
$$
DELIMITER ;
CALL p1();
```

The above example returns:

```
+--------+--------+
| rec1.a | rec1.b |
+--------+--------+
|     10 | b10    |
+--------+--------+
```

A `SELECT...INTO` example for `sql_mode=ORACLE`:

```
SET sql_mode=ORACLE;
DROP TABLE IF EXISTS t1;
DROP PROCEDURE IF EXISTS p1;
CREATE TABLE t1 (a INT, b VARCHAR(32));
INSERT INTO t1 VALUES (10,'b10');
DELIMITER $$
CREATE PROCEDURE p1 AS
  rec1 ROW(a INT, b VARCHAR(32));
BEGIN
  SELECT * FROM t1 INTO rec1;
  SELECT rec1.a, rec1.b;
END;
$$
DELIMITER ;
CALL p1();
```

The above example returns:

```
+--------+--------+
| rec1.a | rec1.b |
+--------+--------+
|     10 | b10    |
+--------+--------+
```

An example for `sql_mode=ORACLE` using `table%ROWTYPE` variables as `SELECT..INTO` targets:

```
SET sql_mode=ORACLE;
DROP TABLE IF EXISTS t1;
DROP PROCEDURE IF EXISTS p1;
CREATE TABLE t1 (a INT, b VARCHAR(32));
INSERT INTO t1 VALUES (10,'b10');
DELIMITER $$
CREATE PROCEDURE p1 AS
  rec1 t1%ROWTYPE;
BEGIN
  SELECT * FROM t1 INTO rec1;
  SELECT rec1.a, rec1.b;
END;
$$
DELIMITER ;
CALL p1();
```

The above example returns:

```
+--------+--------+
| rec1.a | rec1.b |
+--------+--------+
|     10 | b10    |
+--------+--------+
```

An example for `sql_mode=ORACLE` using `cursor%ROWTYPE` variables as `SELECT..INTO` targets:

```
SET sql_mode=ORACLE;
DROP TABLE IF EXISTS t1;
DROP PROCEDURE IF EXISTS p1;
CREATE TABLE t1 (a INT, b VARCHAR(32));
INSERT INTO t1 VALUES (10,'b10');
DELIMITER $$
CREATE PROCEDURE p1 AS
  CURSOR cur1 IS SELECT * FROM t1;
  rec1 cur1%ROWTYPE;
BEGIN
  SELECT * FROM t1 INTO rec1;
  SELECT rec1.a, rec1.b;
END;
$$
DELIMITER ;
CALL p1();
```

The above example returns:

```
+--------+--------+
| rec1.a | rec1.b |
+--------+--------+
|     10 | b10    |
+--------+--------+
```

Row Table example:

```
CREATE TABLE row_table(
  descr VARCHAR(20),
  val INT
);
```

```
INSERT INTO row_table VALUES ('Life', 42);
```

```
DELIMITER $$
CREATE PROCEDURE row_proc()
BEGIN
  DECLARE rec1 ROW(descr VARCHAR(20), val INT);
  SELECT * INTO rec1 FROM row_table;
  SELECT rec1.descr, rec1.val;
END;
$$
DELIMITER ;
```

```
CALL row_proc();

+------------+----------+
| rec1.descr | rec1.val |
+------------+----------+
| Life       |       42 |
+------------+----------+
```

- DECLARE Variable

This page is licensed: CC BY-SA / Gnu FDL

SET Data Type

Syntax

```
SET('value1','value2',...) [CHARACTER SET charset_name] [COLLATE collation_name]
```

Description

A set. A string object that can have zero or more values, each of which must be chosen from the list of values 'value1', 'value2', … A `SET` column can have a maximum of 64 members. `SET` values are represented internally as integers.

`SET` values cannot contain commas.

If a `SET` contains duplicate values, an error will be returned if strict mode is enabled, or a warning if strict mode is not enabled.

EXAMPLES

```
CREATE TABLE set_example (
  description VARCHAR(20),
  example SET('Foo', 'Bar', 'Baz', 'Bob')
);
```

```
INSERT INTO set_example VALUES
  ('1 val', 'Foo'),
  ('2 vals', 'Baz,Foo'),
  ('4 vals', 'Bob,Foo,Bar,Foo,Baz,Bob');
```

```
SELECT * FROM set_example;

+-------------+-----------------+
| description | example         |
+-------------+-----------------+
| 1 val       | Foo             |
| 2 vals      | Foo,Baz         |
| 4 vals      | Foo,Bar,Baz,Bob |
+-------------+-----------------+
```

- Data Type Storage Requirements

This page is licensed: GPLv2, originally from fill_help_tables.sql

TEXT

Syntax

```
TEXT[(M)] [CHARACTER SET charset_name] [COLLATE collation_name]
```

Description

> **Note:**
>
> If you are handling large text data that exceeds the `max_allowed_packet` limit, you can stream the data in chunks using specialized API functions like `mysql_stmt_send_long_data()` or `setCharacterStream()`. See Handling Large Data via APIs for more details.

A `TEXT` column with a maximum length of 65,535 (2^{16} - 1) characters. The effective maximum length is less if the value contains multi-byte characters. Each `TEXT` value is stored using a two-byte length prefix that indicates the number of bytes in the value. If you need a bigger storage, consider using MEDIUMTEXT instead.

An optional length `M` can be given for this type. If this is done, MariaDB creates the column as the smallest `TEXT` type large enough to hold values `M` characters long.

`BLOB` and `TEXT` columns can be assigned a DEFAULT value.

Examples

Trailing spaces:

```
CREATE TABLE strtest (d TEXT(10));
INSERT INTO strtest VALUES('Maria   ');

SELECT d='Maria',d='Maria   ' FROM strtest;
+-----------+--------------+
| d='Maria' | d='Maria   ' |
+-----------+--------------+
|         1 |            1 |
+-----------+--------------+

SELECT d LIKE 'Maria',d LIKE 'Maria   ' FROM strtest;
+---------------+-------------------+
| d LIKE 'Maria' | d LIKE 'Maria   ' |
+---------------+-------------------+
|              0 |                 1 |
+---------------+-------------------+
```

Example of TEXT

```
CREATE TABLE text_example (
   description VARCHAR(20),
   example TEXT
) DEFAULT CHARSET=latin1; -- One byte per char makes the examples clearer
```

```
INSERT INTO text_example VALUES
   ('Normal foo', 'foo'),
   ('Trailing spaces foo', 'foo      '),
   ('NULLed', NULL),
   ('Empty', ''),
   ('Maximum', RPAD('', 65535, 'x'));
```

```
SELECT description, LENGTH(example) AS length
   FROM text_example;
```

```
+---------------------+--------+
| description         | length |
+---------------------+--------+
| Normal foo          |      3 |
| Trailing spaces foo |      9 |
| NULLed              |   NULL |
| Empty               |      0 |
| Maximum             |  65535 |
+---------------------+--------+
```

Data too Long

When `SQL_MODE` is strict (the default) a value is considered "too long" when its length exceeds the size of the data type, and an error is generated.

Example of data too long behavior for `TEXT`:

```
TRUNCATE text_example;

INSERT INTO text_example VALUES
   ('Overflow', RPAD('', 65536, 'x'));
```

```
ERROR 1406 (22001): Data too long for column 'example' at row 1
```

Indexing

A unique index can be created on a `TEXT` column.

Internally, this uses hash indexing to quickly check the values and if a hash collision is found, the actual stored values are compared in order to retain the uniqueness.

Difference between VARCHAR and TEXT

- VARCHAR columns can be fully indexed. `TEXT` columns can only be indexed over a specified length.
- Using `TEXT` or BLOB in a SELECT query that uses temporary tables for storing intermediate results will force the temporary table to be disk based (using the Aria storage engine instead of the memory storage engine, which is a bit slower. This is not that bad as the Aria storage engine caches the rows in memory. To get the benefit of this, one should ensure that the aria_pagecache_buffer_size variable is big enough to hold most of the row and index data for temporary tables.

For Storage Engine Developers

- Internally the full length of the VARCHAR column is allocated inside each TABLE objects record[] structure. As there are three such buffers, each open table will allocate 3 times max-length-to-store-varchar bytes of memory.
- `TEXT` and `BLOB` columns are stored with a pointer (4 or 8 bytes) + a 1-4 bytes length. The `TEXT` data is only stored once. This means that internally `TEXT` uses less memory for each open table but instead has the additional overhead that each `TEXT` object needs to be allocated and freed for each row access (with some caching in between).

TINYBLOB

Syntax

```
TINYBLOB
```

Description

A BLOB column with a maximum length of 255 (2^8 - 1) bytes. Each `TINYBLOB` value is stored using a one-byte length prefix that indicates the number of bytes in the value.

EXAMPLES

TINYBLOB

Example of TINYBLOB:

```
CREATE TABLE tinyblob_example (
   description VARCHAR(20),
   example TINYBLOB
) DEFAULT CHARSET=latin1; -- One byte per char makes the examples clearer
```

```
INSERT INTO tinyblob_example VALUES
   ('Normal foo', 'foo'),
   ('Trailing spaces foo', 'foo      '),
   ('NULLed', NULL),
   ('Empty', ''),
   ('Maximum', RPAD('', 255, CHAR(7)));
```

```
SELECT description, LENGTH(example) AS length
   FROM tinyblob_example;
```

```
+---------------------+--------+
| description         | length |
+---------------------+--------+
| Normal foo          |      3 |
| Trailing spaces foo |      9 |
| NULLed              |   NULL |
| Empty               |      0 |
| Maximum             |    255 |
+---------------------+--------+
```

Data too Long

When `SQL_MODE` is strict (the default), a value is considered “too long” when its length exceeds the size of the data type, and an error is generated.

Example of data too long behavior for `TINYBLOB`:

```
TRUNCATE tinyblob_example;

INSERT INTO tinyblob_example VALUES
   ('Overflow', RPAD('', 256, CHAR(7)));
```

```
ERROR 1406 (22001): Data too long for column 'example' at row 1
```

See Also

- BLOB

- BLOB and TEXT Data Types
- Data Type Storage Requirements

This page is licensed: GPLv2, originally from fill_help_tables.sql

TINYTEXT

Syntax

```
TINYTEXT [CHARACTER SET charset_name] [COLLATE collation_name]
```

Description

A TEXT column with a maximum length of 255 (2^8 - 1) characters. The effective maximum length is less if the value contains multi-byte characters. Each `TINYTEXT` value is stored using a one-byte length prefix that indicates the number of bytes in the value.

EXAMPLES

TINYTEXT

Example of `TINYTEXT`:

```
CREATE TABLE tinytext_example (
   description VARCHAR(20),
   example TINYTEXT
) DEFAULT CHARSET=latin1; -- One byte per char makes the examples clearer
```

```
INSERT INTO tinytext_example VALUES
   ('Normal foo', 'foo'),
   ('Trailing spaces foo', 'foo      '),
   ('NULLed', NULL),
   ('Empty', ''),
   ('Maximum', RPAD('', 255, 'x'));
```

```
SELECT description, LENGTH(example) AS length FROM tinytext_example;
```

```
+--------------------+--------+
| description        | length |
+--------------------+--------+
| Normal foo         |      3 |
| Trailing spaces foo |      9 |
| NULLed             |   NULL |
| Empty              |      0 |
| Maximum            |    255 |
+--------------------+--------+
```

Data too Long

When `SQL_MODE` is strict (the default) a value is considered “too long” when its length exceeds the size of the data type, and an error is generated.

Example of data too long behavior for `TINYTEXT`:

```
TRUNCATE tinytext_example;

INSERT INTO tinytext_example VALUES
   ('Overflow', RPAD('', 256, 'x'));
```

```
ERROR 1406 (22001): Data too long for column 'example' at row 1
```

UUID Data Type

> **Note:**
>
> `UUID` is available from MariaDB 10.7.

Syntax

```
UUID
```

Description

The `UUID` data type is intended for the storage of 128-bit UUID (Universally Unique Identifier) data. See the UUID function page for more details on UUIDs themselves.

Retrieval

Data retrieved by this data type is in the string representation defined in RFC4122.

Casting

String literals of hexadecimal characters and CHAR/VARCHAR/TEXT can be cast to the `UUID` data type. Likewise hexadecimal literals, binary-literals, and BINARY/VARBINARY/BLOB types can also be cast to `UUID`.

The data type will not accept a short `UUID` generated with the UUID_SHORT function, but will accept a value without the `-` character generated by the SYS_GUID function (or inserted directly). Hyphens can be partially omitted as well, or included after any group of two digits.

The type does not accept `UUID` values in braces, permitted by some implementations.

Storage

`UUID` values are stored in an index-friendly manner; the order of a UUID of llllllll-mmmm-Vhhh-vsss-nnnnnnnnnnnn is stored as:

```
nnnnnnnnnnnn-vsss-Vhhh-mmmm-llllllll
```

This provides a sorting order, assuming a UUIDv1 (node and timestamp) is used, of the node, followed by the timestamp. The key aspect is the timestamps are sequential.

MariaDB starting with 10.10

> **CURRENT**
>
> Taking into account that UUIDv7 and other versions are designed around time ordering, `UUID` values version >= 6 are stored without byte-swapping, and `UUID` values with version >=8 and variant=0 are now considered invalid (as the SQL standard suggests).

> **< 10.11.5 / 10.10.6**
>
> `UUID` values version >= 6 are **not** stored without byte-swapping, and `UUID` values with version >=8 and variant=0 are **not** considered invalid.

Examples

```
CREATE TABLE t1 (id UUID);
```

Directly inserting via string literals:

```
INSERT INTO t1 VALUES('123e4567-e89b-12d3-a456-426655440000');
```

Directly Inserting via hexadecimal literals:

```
INSERT INTO t1 VALUES (x'fffffffffffffffffffffffffffffffe');
```

Generating and inserting via the UUID function.

```
INSERT INTO t1 VALUES (UUID());
```

Retrieval:

```
SELECT * FROM t1;
+--------------------------------------+
| id                                   |
+--------------------------------------+
| 123e4567-e89b-12d3-a456-426655440000 |
| ffffffff-ffff-ffff-ffff-fffffffffffe |
| 93aac041-1a14-11ec-ab4e-f859713e4be4 |
+--------------------------------------+
```

The UUID_SHORT function does not generate valid full-length `UUID`:

```
INSERT INTO t1 VALUES (UUID_SHORT());
ERROR 1292 (22007): Incorrect uuid value: '99440417627439104'
  for column `test`.`t1`.`id` at row 1
```

Accepting a value without the `-` character, either directly or generated by the SYS_GUID function:

```
INSERT INTO t1 VALUES (SYS_GUID());

SELECT * FROM t1;
+--------------------------------------+
| id                                   |
+--------------------------------------+
| 123e4567-e89b-12d3-a456-426655440000 |
| ffffffff-ffff-ffff-ffff-fffffffffffe |
| 93aac041-1a14-11ec-ab4e-f859713e4be4 |
| ea0368d3-1a14-11ec-ab4e-f859713e4be4 |
+--------------------------------------+

SELECT SYS_GUID();
+----------------------------------+
| SYS_GUID()                       |
+----------------------------------+
| ff5b6bcc1a1411ecab4ef859713e4be4 |
+----------------------------------+

INSERT INTO t1 VALUES ('ff5b6bcc1a1411ecab4ef859713e4be4');

SELECT * FROM t1;
+--------------------------------------+
| id                                   |
+--------------------------------------+
| 123e4567-e89b-12d3-a456-426655440000 |
| ffffffff-ffff-ffff-ffff-fffffffffffe |
| 93aac041-1a14-11ec-ab4e-f859713e4be4 |
| ea0368d3-1a14-11ec-ab4e-f859713e4be4 |
| ff5b6bcc-1a14-11ec-ab4e-f859713e4be4 |
+--------------------------------------+
```

Valid and invalid hyphen and brace usage:

```
TRUNCATE t1;

INSERT INTO t1 VALUES ('f8aa-ed66-1a1b-11ec-ab4e-f859-713e-4be4');

INSERT INTO t1 VALUES ('1b80667f1a1c-11ecab4ef859713e4be4');

INSERT INTO t1 VALUES ('2fd6c945-1a-1c-11ec-ab4e-f859713e4be4');

INSERT INTO t1 VALUES ('49-c9-f9-59-1a-1c-11ec-ab4e-f859713e4be4');

INSERT INTO t1 VALUES ('57-96-da-c1-1a-1c-11-ec-ab-4e-f8-59-71-3e-4b-e4');

INSERT INTO t1 VALUES ('6-eb74f8f-1a1c-11ec-ab4e-f859713e4be4');

INSERT INTO t1 VALUES ('{29bad136-1a1d-11ec-ab4e-f859713e4be4}');
ERROR 1292 (22007): Incorrect uuid value: '{29bad136-1a1d-11ec-ab4e-f859713e4be4}'
  for column `test`.`t1`.`id` at row 1

SELECT * FROM t1;
+--------------------------------------+
| id                                   |
+--------------------------------------+
| f8aaed66-1a1b-11ec-ab4e-f859713e4be4 |
| 1b80667f-1a1c-11ec-ab4e-f859713e4be4 |
| 2fd6c945-1a1c-11ec-ab4e-f859713e4be4 |
| 49c9f959-1a1c-11ec-ab4e-f859713e4be4 |
| 5796dac1-1a1c-11ec-ab4e-f859713e4be4 |
| 6eb74f8f-1a1c-11ec-ab4e-f859713e4be4 |
+--------------------------------------+
```

VARBINARY

Syntax

```
VARBINARY(M)
```

Description

The `VARBINARY` type is similar to the VARCHAR type, but stores binary byte strings rather than non-binary character strings. `M` represents the maximum column length in bytes.

It contains no character set, and comparison and sorting are based on the numeric value of the bytes.

If the maximum length is exceeded, and SQL strict mode is not enabled , the extra characters will be dropped with a warning. If strict mode is enabled, an error will occur.

Unlike BINARY values, `VARBINARY` values are not right-padded when inserting.

Use Cases for Zero Length

A `BINARY(0)` or `VARBINARY(0)` column is restricted to an empty byte string or `NULL`.

- **Schema Preservation**: Use these columns when a system expects a specific column to exist, but no data storage is required for your current application.
- **Space-Efficient Indicators**: These columns can act as a two-state indicator where the presence of an empty byte string represents one state and `NULL` represents another.

If you attempt to insert a value other than an empty string, MariaDB returns an `ERROR 1406 (22001)` indicating the data is too long for the column.

Oracle Mode

In Oracle mode, `RAW` is a synonym for `VARBINARY`.

Examples

Inserting too many characters, first with strict mode off, then with it on:

```
CREATE TABLE varbins (a VARBINARY(10));

INSERT INTO varbins VALUES('12345678901');
Query OK, 1 row affected, 1 warning (0.04 sec)

SELECT * FROM varbins;
+------------+
| a          |
+------------+
| 1234567890 |
+------------+

SET sql_mode='STRICT_ALL_TABLES';

INSERT INTO varbins VALUES('12345678901');
ERROR 1406 (22001): Data too long for column 'a' at row 1
```

Sorting is performed with the byte value:

```
TRUNCATE varbins;

INSERT INTO varbins VALUES('A'),('B'),('a'),('b');

SELECT * FROM varbins ORDER BY a;
+------+
| a    |
+------+
| A    |
| B    |
| a    |
| b    |
+------+
```

Using CAST to sort as a CHAR instead:

```
SELECT * FROM varbins ORDER BY CAST(a AS CHAR);
+------+
| a    |
+------+
| a    |
| A    |
| b    |
| B    |
+------+
```

VARBINARY

For our example of `VARBINARY`, we picked a maximum size that avoids overflowing the maximum row size (65535). Keep in mind that a multi-byte character set would need more space in the row than a single-byte character set. We also avoid the auto-conversion of a `VARBINARY` into a `BLOB`, `MEDIUMBLOB`, or `LONGBLOB` that can happen when `STRICT_TRANS_TABLES` is not set in the `SQL_MODE`.

The example:

```
CREATE TABLE varbinary_example (
   description VARCHAR(20),
   example VARBINARY(65511)
) DEFAULT CHARSET=latin1; -- One byte per char makes the examples clearer
```

```
INSERT INTO varbinary_example VALUES
   ('Normal foo', 'foo'),
   ('Trailing spaces foo', 'foo      '),
   ('NULLed', NULL),
   ('Empty', ''),
   ('Maximum', RPAD('', 65511, CHAR(7)));
```

```
SELECT description, LENGTH(example) AS length
   FROM varbinary_example;
```

```
+--------------------+--------+
| description        | length |
+--------------------+--------+
| Normal foo         |      3 |
| Trailing spaces foo |      9 |
| NULLed             |   NULL |
| Empty              |      0 |
| Maximum            |  65511 |
+--------------------+--------+
```

Data too Long

When `SQL_MODE` is strict (the default), a value is considered “too long” when its length exceeds the size of the data type, and an error is generated.

Example of data too long behavior for `VARBINARY`:

```
TRUNCATE varbinary_example;

INSERT INTO varbinary_example VALUES
   ('Overflow', RPAD('', 65512, CHAR(7)));
```

```
ERROR 1406 (22001): Data too long for column 'example' at row 1
```

VARCHAR

Syntax

```
[NATIONAL] VARCHAR(M) [CHARACTER SET charset_name] [COLLATE collation_name]
```

Description

A variable-length string. M represents the maximum column length in characters. The range of M is 0 to 65,532. The effective maximum length of a `VARCHAR` is subject to the maximum row size and the character set used. For example, utf-8 characters can require up to three bytes per character, so a `VARCHAR` column that uses the utf-8 character set can be declared to be a maximum of 21,844 characters.

`VARCHAR` is shorthand for `CHARACTER VARYING`. `NATIONAL VARCHAR` is the standard SQL way to define that a `VARCHAR` column should use some predefined character set. MariaDB uses utf-8 as its predefined character set, as does MySQL. `NVARCHAR` is shorthand for `NATIONAL VARCHAR`.

MariaDB stores `VARCHAR` values as a one-byte or two-byte length prefix plus data. The length prefix indicates the number of bytes in the value. A `VARCHAR` column uses one length byte if values require no more than 255 bytes, two length bytes if values may require more than 255 bytes.

MariaDB follows the standard SQL specification and does not remove trailing spaces from `VARCHAR` values.

If a unique index consists of a column where trailing pad characters are stripped or ignored, inserts into that column where values differ only by the number of trailing pad characters will result in a duplicate-key error.

For the ColumnStore engine, M represents the maximum column length in bytes.

For MariaDB, a number of NO PAD collations are available.

`VARCHAR(0)` columns can contain 2 values: an empty string or `NULL`. Such columns cannot be part of an index. The CONNECT storage engine does not support `VARCHAR(0)`.

Use Cases for Zero Length

A `CHAR(0)` or `VARCHAR(0)` column occupies minimal space and is restricted to two possible values: an empty string (`''`) or `NULL`. You can use these columns for the following purposes:

- **Legacy Compatibility**: Include these columns to maintain compatibility with older applications that require a specific table schema, even if the data is no longer collected.
- **Two-State Flags**: A `CHAR(0) NULL` column can function as a boolean indicator. It uses only one bit of storage to distinguish between a “set” state (the empty string) and an “unset” state (`NULL`).
- **Row Marking**: You can use a `CHAR(0)` column to mark a specific row in a table. For example, if you require only one “active” row, set that row to an empty string while keeping all other rows `NULL`.

The following error occurs if you attempt to insert any character data into a 0-length column: `ERROR 1406 (22001): Data too long for column`.

SYNONYMS

The following are synonyms for `VARCHAR`:

- CHAR VARYING
- CHARACTER VARYING
- VARCHAR2
- VARCHARACTER

Examples

The following are equivalent:

```
VARCHAR(30) CHARACTER SET utf8
NATIONAL VARCHAR(30)
NVARCHAR(30)
NCHAR VARCHAR(30)
NATIONAL CHARACTER VARYING(30)
NATIONAL CHAR VARYING(30)
```

Trailing spaces

```
CREATE TABLE strtest (v VARCHAR(10));
INSERT INTO strtest VALUES('Maria   ');

SELECT v='Maria',v='Maria   ' FROM strtest;
+-----------+--------------+
| v='Maria' | v='Maria   ' |
+-----------+--------------+
|         1 |            1 |
+-----------+--------------+

SELECT v LIKE 'Maria',v LIKE 'Maria   ' FROM strtest;
+----------------+-------------------+
| v LIKE 'Maria' | v LIKE 'Maria   ' |
+----------------+-------------------+
|              0 |                 1 |
+----------------+-------------------+
```

VARCHAR

For our example of `VARCHAR`, we picked a maximum size that avoids overflowing the maximum row size (65535). Keep in mind that a multi-byte character set would need more space in the row than a single-byte character set. We also avoid the auto-conversion of a `VARCHAR` into a `TEXT`, `MEDIUMTEXT`, or `LONGTEXT` that can happen when `STRICT_TRANS_TABLES` is not set in the `SQL_MODE`.

The example:

```
CREATE TABLE varchar_example (
   description VARCHAR(20),
   example VARCHAR(65511)
) DEFAULT CHARSET=latin1; -- One byte per char makes the examples clearer
```

```
INSERT INTO varchar_example VALUES
   ('Normal foo', 'foo'),
   ('Trailing spaces foo', 'foo      '),
   ('NULLed', NULL),
   ('Empty', ''),
   ('Maximum', RPAD('', 65511, 'x'));
```

```
SELECT description, LENGTH(example) AS length
   FROM varchar_example;
```

```
+---------------------+--------+
| description         | length |
+---------------------+--------+
| Normal foo          |      3 |
| Trailing spaces foo |      9 |
| NULLed              |   NULL |
| Empty               |      0 |
| Maximum             |  65511 |
+---------------------+--------+
```

Data too Long

When `SQL_MODE` is strict (the default), a value is considered “too long” when its length exceeds the size of the data type, and an error is generated.

Example of data too long behavior for `VARCHAR`:

```
TRUNCATE varchar_example;

INSERT INTO varchar_example VALUES
   ('Overflow', RPAD('', 65512, 'x'));
```

```
ERROR 1406 (22001): Data too long for column 'example' at row 1
```

Storage on Disk

`VARCHAR` is a standard variable-length data type. `VARCHAR` values are stored **in-table (in-row)**, where the actual string data is part of the table record.

Each value is stored as a one-byte or two-byte length prefix followed by the data. The length prefix specifies the number of bytes contained in the value.

This differs from `TEXT` and `BLOB` data types, which are typically stored **off-row**, with only a pointer stored in the table record.

> **Note:** References to multiple buffers for `VARCHAR` specify internal memory usage for table operations. This does not indicate that `VARCHAR` values are stored in memory rather than on disk.

The exact storage behavior may vary depending on the storage engine. For the specific byte-calculation formulas and limits, see Data Type Storage Requirements.

Truncation

- Depending on whether or not strict sql mode is set, you will either get a warning or an error if you try to insert a string that is too long into a `VARCHAR` column. If the extra characters are spaces, the spaces that can't fit will be removed, and you will always get a warning, regardless of the sql mode setting.

Difference Between VARCHAR and TEXT

- **Indexing differences**: `VARCHAR` columns can be fully indexed. TEXT columns can only be indexed over a specified length.
- **Temporary table behavior**: Using TEXT or BLOB in a SELECT query that uses temporary tables for storing intermediate results will force the temporary table to be disk-based (using the Aria storage engine instead of the memory storage engine, which is a bit slower. This is not that bad, as the Aria storage engine caches the rows in memory. To get the benefit of this, one should ensure that the aria_pagecache_buffer_size variable is big enough to hold most of the row and index data for temporary tables.
- **Storage characteristics**: Although both can overflow, `TEXT` is primarily designed for off-page storage, beginning with a pointer in the main row. In contrast, `VARCHAR` is optimized to remain in-page and only overflows when row size limits necessitate it.

Oracle Mode

In Oracle mode, `VARCHAR2` is a synonym.

For Storage Engine Developers

- Internally, the full length of the `VARCHAR` column is allocated inside each `TABLE` objects record[] structure. As there are three such buffers, each open table will allocate 3 times the max-length-to-store-varchar bytes of memory.
- TEXT and BLOB columns are stored with a pointer (4 or 8 bytes) + a 1-4 byte length. The TEXT data is only stored once. This means that internally `TEXT` uses less memory for each open table but instead has the additional overhead that each `TEXT` object needs to be allocated and freed for each row access (with some caching in between).

VARCHAR2

Overview

This is a synonym for VARCHAR.

EXAMPLES

```
SET sql_mode='oracle';

CREATE TABLE varchar2_example (
  example VARCHAR2(32)
);
```

```
SHOW CREATE TABLE varchar2_example\G
```

```
*************************** 1. row ***************************
       Table: varchar2_example
Create Table: CREATE TABLE "varchar2_example" (
  "example" varchar(32) DEFAULT NULL
)
```

This page is: Copyright © 2026 MariaDB. All rights reserved.

VARCHARACTER

Overview

See VARCHAR.

EXAMPLES

```
CREATE TABLE varcharacter_example (
  example VARCHARACTER(32)
);
```

```
SHOW CREATE TABLE varcharacter_example\G

*************************** 1. row ***************************
       Table: varcharacter_example
Create Table: CREATE TABLE `varcharacter_example` (
  `example` varchar(32) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

This page is: Copyright © 2026 MariaDB. All rights reserved.

XMLTYPE

Introduced

MariaDB 12.3

Syntax

```
XMLTYPE
```

- No parameters accepted
- Length specification for `XMLTYPE` (e.g., `XMLTYPE(100)`) results in an error

Description

`XMLTYPE` is a data type introduced in MariaDB 12.3 for storing XML data. It is designed to:

- Provide convenient storage of XML data
- Ensure compatibility with Oracle databases
- Support future XML validation and processing capabilities

In its initial implementation, `XMLTYPE` provides basic XML storage capabilities only, without validation or specialized XML-specific functionality. When using string functions, the data type is effectively converted to strings and is maintained in temporary tables.

Characteristics

- Maximum storage capacity: 4GB (same as `LONGBLOB`)
- Compatibility: Designed to be compatible with Oracle's `XMLTYPE`
- Validation: XML validation or schema enforcement is not supported
- Length restriction: Length cannot be specified.

Example (invalid usage):

```
CREATE TABLE t1 (a XMLTYPE(6));
```

`XMLTYPE` does not accept length parameters, unlike data types such as `VARCHAR(255)` or `DECIMAL(10,2)`.

Related Functions

With MariaDB 12.3, the following functions return the `XMLTYPE` data type:

- `UPDATEXML`
- `CAST`

Examples

Basic Tables Creation

```
CREATE TABLE t1(id INT, x xmltype);
SHOW CREATE TABLE t1;
```

Output

```
Table   Create Table
t1  CREATE TABLE `t1` (
  `id` int(11) DEFAULT NULL,
  `x` xmltype DEFAULT NULL
) ENGINE=MyISAM DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_uca1400_ai_ci
```

Character Set Specification

```
CREATE TABLE t1(id INT, x xmltype  CHARACTER SET utf8mb3) CHARACTER SET utf8mb4;
SHOW CREATE TABLE t1;
```

Output

```
Table   Create Table
t1  CREATE TABLE `t1` (
  `id` int(11) DEFAULT NULL,
  `x` xmltype CHARACTER SET utf8mb3 COLLATE utf8mb3_uca1400_ai_ci DEFAULT NULL
) ENGINE=MyISAM DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_uca1400_ai_ci
```

Binary Attribute

```
CREATE TABLE t1 (a xmltype binary) CHARACTER SET utf8mb4;
SHOW CREATE TABLE t1;
```

Output

```
Table   Create Table
t1  CREATE TABLE `t1` (
  `a` xmltype CHARACTER SET utf8mb4 COLLATE utf8mb4_bin DEFAULT NULL
) ENGINE=MyISAM DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_uca1400_ai_ci
```

Basic Data Insertion and Selection

```
CREATE TABLE t1(id INT, x xmltype);
INSERT INTO t1 VALUES (1, 'one'), (2, 'two'), (3, 'three');
SELECT * FROM t1;
```

Output

```
id  x
1    one
2    two
3    three
```

Restrictions and Error Cases

Length Specification Not Permitted

If a length parameter is provided for `XMLTYPE`, the system returns an error:

```
CREATE TABLE t1 (a XMLTYPE(6));
```

Output

```
ERROR HY000: Data type 'XMLTYPE' doesn't support LENGTH attribute.
```

REF_SYSTEM_ID Attribute Not Supported

```
CREATE TABLE t1 (a XMLTYPE REF_SYSTEM_ID=4);
```

Output

```
ERROR HY000: Data type 'XMLTYPE' doesn't support REF_SYSTEM_ID attribute.
```

Length Parameters in Complex Column Definitions

```
CREATE TABLE t1(id INT, x xmltype(10, 2));
```

Output

```
ERROR HY000: Data type 'xmltype' doesn't support LENGTH attribute.
```

Character Set and Collation Overview

What are Character Sets and Collations?

A character set is a set of characters, while a collation comprises the rules for comparing and sorting a particular character set.

For example, a subset of a character set could consist of the letters `A`, `B` and `C`. A default collation could define these as appearing in an ascending order of `A, B, C`.

If we consider different case characters, more complexity is added. A binary collation would evaluate the characters `A` and `a` differently, ordering them in a particular way. A case-insensitive collation would evaluate `A` and `a` equivalently, while the German phone book collation evaluates the characters `ue` and `ü` equivalently.

A character set can have many collations associated with it, while each collation is only associated with one character set. In MariaDB, the character set name is always part of the collation name. For example, the `latin1_german1_ci` collation applies only to the `latin1` character set. Each character set also has one default collation. The `latin1` default collation is `latin1_swedish_ci`.

As an example, by default, the character `y` comes between `x` and `z`, while in Lithuanian, it's sorted between `i` and `k`. Similarly, the German phone book order is different to the German dictionary order, so while they share the same character set, the collation is different.

Viewing Character Sets and Collations

> **CURRENT**
>
> The default character set is `utf8mb4` and the default collation is `utf8mb4_uca1400_ai_ci`.
> This may differ in some distros, see for example Differences in MariaDB in Debian.
>
> **< 11.6**
>
> The default character set is `latin1` and the default collation is `latin1_swedish_ci`.
> This may differ in some distros, see for example Differences in MariaDB in Debian.

You can view a full list of character sets and collations supported by MariaDB at Supported Character Sets and Collations, or see what's supported on your server with the SHOW CHARACTER SET and SHOW COLLATION commands.

By default, `A` comes before `Z`, so the following evaluates to true:

```
SELECT "A" < "Z";
+-----------+
| "A" < "Z" |
+-----------+
|         1 |
+-----------+
```

By default, comparisons are case-insensitive:

```
SELECT "A" < "a", "A" = "a";
+-----------+-----------+
| "A" < "a" | "A" = "a" |
+-----------+-----------+
|         0 |         1 |
+-----------+-----------+
```

Changing Character Sets and Collations

Character sets and collations can be set from the server level right down to the column level, as well as for client-server communication.

For example, `ue` and `ü` are by default evaluated differently.

```
SELECT 'Mueller' = 'Müller';
+----------------------+
| 'Müller' = 'Mueller' |
+----------------------+
|                    0 |
+----------------------+
```

By using the collation_connection system variable to change the connection character set to `latin1_german2_ci`, or German phone book, the same two characters will evaluate as equivalent.

```
SET collation_connection = latin1_german2_ci;

SELECT 'Mueller' = 'Müller';
+-----------------------+
| 'Mueller' = 'Müller'  |
+-----------------------+
|                     1 |
+-----------------------+
```

Setting Character Sets and Collations

> **CURRENT**
>
> The default character set is `utf8mb4` and the default collation is `utf8mb4_uca1400_ai_ci`.
> This may differ in some distros, see for example Differences in MariaDB in Debian.
>
> **< 11.6**
>
> The default character set is `latin1` and the default collation is `latin1_swedish_ci`.
> This may differ in some distros, see for example Differences in MariaDB in Debian.

> **Warning:**
>
> In MariaDB 11.6, the default character set changed from `latin1` to `utf8mb4`.
>
> When upgrading to 11.6 or above from a previous release series, this can lead to behavior different from what you've been seeing in the old version.
>
> See this section for details, including the impact on replicating to older MariaDB (or MySQL) replicas.

The character sets and the collations can be specified from the server right down to the column level, as well as for client-server connections. When changing a character set and not specifying a collation, the default collation for the new character set is always used.

Character sets and collations always cascade down, so a column without a specified collation will look for the table default, the table for the database, and the database for the server. It's therefore possible to have extremely fine-grained control over all the character sets and collations used in your data.

Default collations for each character set can be viewed with the SHOW COLLATION statement, for example, to find the default collation for the latin2 character set:

```
SHOW COLLATION LIKE 'latin2%';
+--------------------+---------+----+---------+----------+---------+
| Collation          | Charset | Id | Default | Compiled | Sortlen |
+--------------------+---------+----+---------+----------+---------+
| latin2_czech_cs    | latin2  |  2 |         | Yes      |       4 |
| latin2_general_ci  | latin2  |  9 | Yes     | Yes      |       1 |
| latin2_hungarian_ci | latin2  | 21 |         | Yes      |       1 |
| latin2_croatian_ci | latin2  | 27 |         | Yes      |       1 |
| latin2_bin         | latin2  | 77 |         | Yes      |       1 |
+--------------------+---------+----+---------+----------+---------+
```

Server Level

The character_set_server system variable can be used to change the default server character set. It can be set both on startup or dynamically, with the SET command:

```
SET character_set_server = 'latin2';
```

Similarly, the collation_server variable is used for setting the default server collation.

```
SET collation_server = 'latin2_czech_cs';
```

Database Level

The CREATE DATABASE and ALTER DATABASE statements have optional character set and collation clauses. If these are left out, the server defaults are used.

```
CREATE DATABASE czech_slovak_names
  CHARACTER SET = 'keybcs2'
  COLLATE = 'keybcs2_bin';
```

```
ALTER DATABASE czech_slovak_names COLLATE = 'keybcs2_general_ci';
```

To determine the default character set used by a database, use:

```
SHOW CREATE DATABASE czech_slovak_names;
+--------------------+-----------------------------------------------------------------------------------+
| Database           | Create Database                                                                   |
+--------------------+-----------------------------------------------------------------------------------+
| czech_slovak_names | CREATE DATABASE `czech_slovak_names` /*!40100 DEFAULT CHARACTER SET keybcs2 */ |
+--------------------+-----------------------------------------------------------------------------------+
```

Alternatively, for the character set and collation:

```
SELECT * FROM INFORMATION_SCHEMA.SCHEMATA;
+--------------+--------------------+----------------------------+------------------------+----------+
| CATALOG_NAME | SCHEMA_NAME        | DEFAULT_CHARACTER_SET_NAME | DEFAULT_COLLATION_NAME | SQL_PATH |
+--------------+--------------------+----------------------------+------------------------+----------+
| def          | czech_slovak_names | keybcs2                    | keybcs2_general_ci     | NULL     |
| def          | information_schema | utf8                       | utf8_general_ci        | NULL     |
| def          | mysql              | latin1                     | latin1_swedish_ci      | NULL     |
| def          | performance_schema | utf8                       | utf8_general_ci        | NULL     |
| def          | test               | latin1                     | latin1_swedish_ci      | NULL     |
+--------------+--------------------+----------------------------+------------------------+----------+
```

It is also possible to specify only the collation, and, since each collation only applies to one character set, the associated character set will automatically be specified.

```
CREATE DATABASE danish_names COLLATE 'utf8_danish_ci';

SHOW CREATE DATABASE danish_names;
+--------------+-----------------------------------------------------------------------------------------------
-----+
| Database     | Create Database
|
+--------------+-----------------------------------------------------------------------------------------------
-----+
| danish_names | CREATE DATABASE `danish_names` /*!40100 DEFAULT CHARACTER SET utf8 COLLATE
utf8_danish_ci */ |
+--------------+-----------------------------------------------------------------------------------------------
-----+
```

Although there are character_set_database and collation_database system variables which can be set dynamically, these are used for determining the character set and collation for the default database, and should only be set by the server.

A database's collation is inherited only by statements that don't name a character set of their own. A `CREATE TABLE` that names one, such as `CREATE TABLE ... DEFAULT CHARACTER SET utf8mb4`, takes its collation from the character_set_collations map instead. See Table Level and Changing Default Collation.

Table Level

The CREATE TABLE and ALTER TABLE statements support optional character set and collation clauses, a MariaDB and MySQL extension to standard SQL.

```
CREATE TABLE english_names (id INT, name VARCHAR(40))
  CHARACTER SET 'utf8'
  COLLATE 'utf8_icelandic_ci';
```

If neither character set nor collation is provided, the database default will be used. If only the character set is provided, the default collation for that character set will be used. If only the collation is provided, the associated character set will be used. See Supported Character Sets and Collations.

Warning:

Naming a character set without a `COLLATE` clause does **not** inherit the database's collation. The collation comes from the character_set_collations map instead, which has a non-empty default value since MariaDB 11.5. So these two statements can produce different collations in the same database:

```
CREATE TABLE t1 (id VARCHAR(24));                               -- inherits the database collation
CREATE TABLE t2 (id VARCHAR(24)) DEFAULT CHARACTER SET utf8mb4;  -- uses character_set_collations
```

In a database whose default collation is `utf8mb4_general_ci`, `t1` is `utf8mb4_general_ci` while `t2` is `utf8mb4_uca1400_ai_ci`. To get the same result from both, either add an explicit `COLLATE` clause or change the map — see Changing Default Collation.

```
ALTER TABLE table_name
 CONVERT TO CHARACTER SET charset_name [COLLATE collation_name];
```

If no collation is provided, the collation will be set to the default collation for that character set. See Supported Character Sets and Collations.

For VARCHAR or TEXT columns, `CONVERT TO CHARACTER SET` changes the data type if needed to ensure the new column is long enough to store as many characters as the original column.

For example, an ascii `TEXT` column requires a single byte per character, so the column can hold up to 65,535 characters. If the column is converted to `utf8mb4`, 4 bytes can be required for each character, so the column will be

converted to MEDIUMTEXT to be able to hold the same number of characters.

`CONVERT TO CHARACTER SET binary` will convert CHAR, VARCHAR and TEXT columns to BINARY, VARBINARY and BLOB respectively, and from that point will no longer have a character set, or be affected by future `CONVERT TO CHARACTER SET` statements.

To avoid data type changes resulting from `CONVERT TO CHARACTER SET`, use `MODIFY` on the individual columns instead. For example:

```
ALTER TABLE table_name MODIFY ascii_text_column TEXT CHARACTER SET utf8;
ALTER TABLE table_name MODIFY ascii_varchar_column VARCHAR(M) CHARACTER SET utf8;
```

Column Level

Character sets and collations can also be specified for columns that are character types `CHAR`, `TEXT` or `VARCHAR`. The CREATE TABLE and ALTER TABLE statements support optional character set and collation clauses for this purpose - unlike those at the table level, the column level definitions are standard SQL.

```
CREATE TABLE european_names (
  croatian_names VARCHAR(40) COLLATE 'cp1250_croatian_ci',
  greek_names VARCHAR(40) CHARACTER SET 'greek');
```

If neither collation nor character set is provided, the table default is used. If only the character set is specified, that character set's default collation is used, while if only the collation is specified, the associated character set is used.

When using ALTER TABLE to change a column's character set, you need to ensure the character sets are compatible with your data. MariaDB will map the data as best it can, but it's possible to lose data if care is not taken.

The SHOW CREATE TABLE statement or `INFORMATION SCHEMA` database can be used to determine column character sets and collations.

```
SHOW CREATE TABLE european_names\G
*************************** 1. row ***************************
       Table: european_names
Create Table: CREATE TABLE `european_names` (
  `croatian_names` varchar(40) CHARACTER SET cp1250 COLLATE cp1250_croatian_ci DEFAULT NULL,
  `greek_names` varchar(40) CHARACTER SET greek DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8 COLLATE=utf8_danish_ci
```

```
SELECT * FROM INFORMATION_SCHEMA.COLUMNS WHERE TABLE_NAME LIKE 'european%'\G
*************************** 1. row ***************************
           TABLE_CATALOG: def
            TABLE_SCHEMA: danish_names
              TABLE_NAME: european_names
             COLUMN_NAME: croatian_names
        ORDINAL_POSITION: 1
          COLUMN_DEFAULT: NULL
             IS_NULLABLE: YES
               DATA_TYPE: varchar
CHARACTER_MAXIMUM_LENGTH: 40
  CHARACTER_OCTET_LENGTH: 40
       NUMERIC_PRECISION: NULL
           NUMERIC_SCALE: NULL
      DATETIME_PRECISION: NULL
      CHARACTER_SET_NAME: cp1250
          COLLATION_NAME: cp1250_croatian_ci
             COLUMN_TYPE: varchar(40)
              COLUMN_KEY:
                   EXTRA:
              PRIVILEGES: select,insert,update,references
          COLUMN_COMMENT:
*************************** 2. row ***************************
           TABLE_CATALOG: def
            TABLE_SCHEMA: danish_names
              TABLE_NAME: european_names
             COLUMN_NAME: greek_names
        ORDINAL_POSITION: 2
          COLUMN_DEFAULT: NULL
             IS_NULLABLE: YES
               DATA_TYPE: varchar
CHARACTER_MAXIMUM_LENGTH: 40
  CHARACTER_OCTET_LENGTH: 40
       NUMERIC_PRECISION: NULL

      DATETIME_PRECISION: NULL
      CHARACTER_SET_NAME: greek
          COLLATION_NAME: greek_general_ci
             COLUMN_TYPE: varchar(40)
              COLUMN_KEY:
                   EXTRA:
              PRIVILEGES: select,insert,update,references
          COLUMN_COMMENT:
```

Filenames

The character_set_filesystem system variable has controlled interpretation of file names that are given as literal strings. This affects the following statements and functions:

- SELECT INTO DUMPFILE
- SELECT INTO OUTFILE
- LOAD DATA INFILE
- LOAD XML
- LOAD_FILE()

Literals

By default, the character set and collation used for literals is determined by the character_set_connection and collation_connection system variables. However, they can also be specified explicitly:

```
[_charset_name]'string' [COLLATE collation_name]
```

The character set of string literals that do not have a character set introducer is determined by the character_set_connection system variable.

This query always returns the same character set name in both columns.:

```
SELECT CHARSET('a'), @@character_set_connection;
```

character_set_client and character_set_connection are normally (e.g. during handshake, or after a `SET NAMES` query) are set to equal values. However, it's possible to set to different values.

Examples

Examples when setting `@@character_set_client` and `@@character_set_connection` to different values can be useful:

Example 1:

Suppose, we have a `utf8` database with this table:

```
CREATE TABLE t1 (a VARCHAR(10)) CHARACTER SET utf8 COLLATE utf8_general_ci;
INSERT INTO t1 VALUES ('oe'),('ö');
```

Now we connect to it using a client which uses the DOS character set (cp850 on a West European machine), and want to fetch all records that are equal to 'ö' according to the German phonebook rules.

It's possible with the following:

```
SET @@character_set_client=cp850, @@character_set_connection=utf8;
SELECT a FROM t1 WHERE a='ö' COLLATE utf8_german2_ci;
```

This will return:

```
+------+
| a    |
+------+
| oe   |
| ö    |
+------+
```

It works as follows:

1. The client sends the query using `cp850`.
2. The server, when parsing the query, creates a utf8 string literal by converting 'ö' from `@@character_set_client` (cp850) to `@@character_set_connection` (utf8).
3. The server applies the collation `utf8_german2_ci` to this string literal.
4. The server uses `utf8_german2_ci` for comparison.

Note, if we rewrite the script like this:

```
SET NAMES cp850;
SELECT a FROM t1 WHERE a='ö' COLLATE utf8_german2_ci;
```

We get an error:

```
ERROR 1253 (42000): COLLATION 'utf8_german2_ci' is not valid for CHARACTER SET 'cp850'
```

Reason:

- In step #2, the literal is not converted to `utf8` any more and is created using `cp850`.

- In step #3, the server fails to apply `utf8_german2_ci` to an `cp850` string literal.

Example 2:

Suppose we have a utf8 database and use “mysql.exe” from a West European machine again.

We can do this:

```
SET @@character_set_client=cp850, @@character_set_connection=utf8;
CREATE TABLE t2 AS SELECT 'ö';
```

It creates a table with a column of the type `VARCHAR(1) CHARACTER SET utf8`.

Note, if we rewrite the query like this:

```
SET NAMES cp850;
CREATE TABLE t2 AS SELECT 'ö';
```

It creates a table with a column of the type `VARCHAR(1) CHARACTER SET cp850`, which is probably not a good idea.

N

Also, `N` or `n` can be used as prefix to convert a literal into the National Character set (which in MariaDB is always `utf8`).

For example:

```
SELECT _latin2 'Müller';
+-----------+
| MÄźller   |
+-----------+
| MÄźller   |
+-----------+
```

CURRENT

```
SELECT CHARSET(N'a string');
+----------------------+
| CHARSET(N'a string') |
+----------------------+
| utf8mb3              |
+----------------------+
```

```
SELECT 'Mueller' = 'Müller' COLLATE 'latin1_german2_ci';
+-----------------------------------------------------+
| 'Mueller' = 'Müller' COLLATE 'latin1_german2_ci'  |
+-----------------------------------------------------+
|                                                   1 |
+-----------------------------------------------------+
```

< 10.6

```
SELECT CHARSET(N'a string');
+----------------------+
| CHARSET(N'a string') |
+----------------------+
| utf8                 |
+----------------------+
```

Stored Programs and Views

The literals which occur in stored programs and views, by default, use the character set and collation which was specified by the character_set_connection and collation_connection system variables when the stored program was created. These values can be seen using the `SHOW CREATE` statements. To change the character sets used for literals in an existing stored program, it is necessary to drop and recreate the stored program.

For stored routines parameters and return values, a character set and a collation can be specified via the `CHARACTER SET` and `COLLATE` clauses.

The following example shows that the character set and collation are determined at the time of creation:

```
SET @@local.character_set_connection='latin1';

DELIMITER ||
CREATE PROCEDURE `test`.`x`()
BEGIN
    SELECT CHARSET('x');
END;
||
Query OK, 0 rows affected (0.00 sec)

DELIMITER ;
SET @@local.character_set_connection='utf8';

CALL `test`.`x`();
+--------------+
| CHARSET('x') |
+--------------+
| latin1       |
+--------------+
```

The following example shows how to specify a function parameters character set and collation:

```
CREATE FUNCTION `test`.`y`(`str` TEXT CHARACTER SET utf8 COLLATE utf8_bin)
    RETURNS TEXT CHARACTER SET latin1 COLLATE latin1_bin
BEGIN
    SET @param_coll = COLLATION(`str`);
    RETURN `str`;
END;

-- return value's collation:
SELECT COLLATION(`test`.`y`('Hello, planet!'));
+----------------------------------------+
| COLLATION(`test`.`y`('Hello, planet!')) |
+----------------------------------------+
| latin1_bin                             |
+----------------------------------------+

-- parameter's collation:
SELECT @param_coll;
+-------------+
| @param_coll |
+-------------+
| utf8_bin    |
+-------------+
```

Changing Default Collation

> **CURRENT**
>
> The default collation associated with a particular character set is determined by the character_set_collations system variable, which accepts a comma-delimited list of character sets and their default collations, for example:

```
SET @@character_set_collations = 'utf8mb4=uca1400_ai_ci, latin2=latin2_hungarian_ci';
```

The variable is **not** empty by default. Since MariaDB 11.5, its default value maps every Unicode character set to a UCA 14.0.0 collation, so the map applies even on a server where nobody has ever set the variable. To see the value in effect:

```
SELECT @@character_set_collations;
+-----------------------------------------------------------------------------------------------------------
----------------------------------+
| @@character_set_collations
|
+-----------------------------------------------------------------------------------------------------------
----------------------------------+
|
utf8mb3=utf8mb3_uca1400_ai_ci,ucs2=ucs2_uca1400_ai_ci,utf8mb4=utf8mb4_uca1400_ai_ci,utf16=utf16_uca1400_
ai_ci,utf32=utf32_uca1400_ai_ci |
+-----------------------------------------------------------------------------------------------------------
----------------------------------+
```

A collation can be given either by its full name, such as `utf8mb4_uca1400_ai_ci`, or by the shorter family name that applies to any character set, such as `uca1400_ai_ci`. The server stores the full name, so the value it reports back is always the expanded form.

< 11.5

The variable exists but is empty by default, so each character set uses its compiled-in default collation, such as `utf8mb4_general_ci` for `utf8mb4`.

< 11.2.1

It is **not** possible to change the default collation associated with a particular character set.

The variable takes effect in all cases where a character set is explicitly or implicitly specified without an explicit `COLLATE` clause, including but not limited to:

- Column collation
- Table collation
- Database collation
- `CHAR` (expr `USING` csname)
- `CONVERT` (expr `USING` csname)
- `CAST` (expr `AS CHAR CHARACTER SET` csname)
- '' - character string literal
- `_utf8mb3'text'` - a character string literal with an introducer
- `_utf8mb3 X'61'` - a character string literal with an introducer with hex notation
- `_utf8mb3 0x61` - a character string literal with an introducer with hex hybrid notation
- `@@collation_connection` after a `SET NAMES` statement without `COLLATE`

Overriding the Map for One Character Set

Assigning to the variable **replaces the entire map**; it does not merge with the value already in effect. Setting only `utf8mb4` therefore returns the other Unicode character sets to their compiled-in defaults:

```
SET GLOBAL character_set_collations = 'utf8mb4=utf8mb4_general_ci';
```

To change `utf8mb4` while keeping the UCA 14.0.0 defaults for the rest, list them all:

```
SET GLOBAL character_set_collations =

'utf8mb3=uca1400_ai_ci,ucs2=uca1400_ai_ci,utf16=uca1400_ai_ci,utf32=uca1400_ai_ci,utf8mb4=utf8mb4_general
_ci';
```

To make either change permanent, set it in a configuration file:

```
[mariadbd]
character-set-collations = utf8mb4=utf8mb4_general_ci
```

Note:

`SET GLOBAL` affects new connections only. Existing connections keep the session value they inherited when they connected, so reconnect the application before relying on the new map.

Default Character Set and Collation Changes

Note:

The default character set and collation changed in MariaDB 11.6. Separately, the default collation applied to an explicitly named Unicode character set changed in MariaDB 11.5 — see Changing Default Collation.

MariaDB 11.8 is the first long-term support release containing either change, so both take effect at once when upgrading from an earlier long-term support release such as MariaDB 10.6 or 11.4.

The default character set has changed from `latin1` to `utf8mb4`, and the default collation has changed from `latin1_swedish_ci` to `utf8mb4_uca1400_ai_ci`. This update improves global compatibility and supports modern data requirements, such as emojis.

Why the Defaults Changed

The shift to `utf8mb4` and UCA-based collations provides several benefits:

- Global Compatibility: The new defaults support users worldwide without requiring additional configuration, whereas the previous `latin1` defaults were primarily suited for West European languages.
- Supplementary Character Support: You can now store supplementary characters, such as emojis, which were not supported by `latin1`.
- Accurate Sorting and Comparison: The `utf8mb4_uca1400_ai_ci` collation correctly handles supplementary characters and supports expansions and contractions from the Default Unicode Collation Element Table (DUCET). For example, the German character “ß” is correctly compared as equal to “ss”.

Important Considerations

Before upgrading, please be aware of the following technical implications:

- The storage overhead for `CHAR(N)` indeed significantly increases. The server reserved `N` bytes for a `CHAR(N) CHARACTER SET latin1` column in every record. Now it must reserve `N*4` bytes for a `CHAR(N) CHARACTER SET utf8mb4` column, and fill the unused bytes with trailing spacing.
- The storage overhead for a `VARCHAR(N)` is not really palpable because the server only stores actual strings without padding. West European languages mostly use basic ASCII letters, only rarely accented letters. For example, for German, the letter use statistics is here: https://www.sttmedia.com/characterfrequency-german. After switching from latin1 to utf8mb4, only accented letters need more storage, but since they’re making up only for a small portion, the overall growth is insignificant.
- The previous two points indicate that it might be worthwhile to consider switching from `CHAR` to `VARCHAR` columns.

- Replication Impact: Because `utf8mb4_uca1400_ai_ci` was not available in earlier versions, replication from MariaDB 11.8 to MariaDB 10.6 will fail unless the server is configured to use the old defaults.
- Storage Overhead: Using `utf8mb4` may increase storage requirements for `CHAR` and `VARCHAR` columns, particularly for data containing non-ASCII characters. This is particularly true when table columns contain `latin1` code points outside of the ASCII range.
- Performance: Some comparison operations may be slower with the new collation compared to the fixed-width `latin1_swedish_ci` collation.
- Application Compatibility: Some applications that rely on `latin1` behavior may require updates to function correctly with the new defaults. Problems can occur because a `latin1` column can always compare to a binary string, while a `utf8mb4` column cannot (at least not always), because not every binary string is a well-formed `utf8mb4` string. A workaround is to cast the `utf8mb4` column to `BINARY` before doing a comparison.

Restoring Old Defaults

If you need to maintain compatibility with MariaDB 10.6 replicas or require the specific performance characteristics of the previous defaults, you can configure the server to use the old settings.

To return to the `latin1` defaults, add the following lines to your `my.cnf` configuration file:

```
[mariadb]
character-set-server=latin1
collation-server=latin1_swedish_ci
character-set-collations=''
```

> Note: These settings make data files compatible with older versions like MariaDB 10.6, which lack the newer UCA collation support.

Example: Changing the Default Character Set To UTF-8

To change the default character set from latin1 to UTF-8, the following settings should be specified in the my.cnf configuration file.

```
[mysql]
...
default-character-set=utf8mb4
...
[mysqld]
...
collation-server = utf8mb4_unicode_ci
init-connect='SET NAMES utf8mb4'
character-set-server = utf8mb4
...
```

Note that the `default-character-set` option is a client option, not a server option.

Supported Character Sets and Collations

Character Sets

You can see which character sets are available in a particular version by running the SHOW CHARACTER SET statement or by querying the Information Schema CHARACTER_SETS Table.

> **CURRENT**
>
> It is possible to change the default collation associated with a character set. See Changing Default Collation.
>
> **< 11.2**
>
> It is **not** possible to change the default collation associated with a character set. See Changing Default Collation

MariaDB supports the following character sets:

Charset	Description	Default collation	Maxlen
armscii8	ARMSCII-8 Armenian	armscii8_general_ci	1
ascii	US ASCII	ascii_general_ci	1
big5	Big5 Traditional Chinese	big5_chinese_ci	2
binary	Binary pseudo charset	binary	1
cp1250	Windows Central European	cp1250_general_ci	1
cp1251	Windows Cyrillic	cp1251_general_ci	1
cp1256	Windows Arabic	cp1256_general_ci	1
cp1257	Windows Baltic	cp1257_general_ci	1
cp850	DOS West European	cp850_general_ci	1
cp852	DOS Central European	cp852_general_ci	1
cp866	DOS Russian	cp866_general_ci	1
cp932	SJIS for Windows Japanese	cp932_japanese_ci	2
dec8	DEC West European	dec8_swedish_ci	1
eucjpms	UJIS for Windows Japanese	eucjpms_japanese_ci	3
euckr	EUC-KR Korean	euckr_korean_ci	2
gb2312	GB2312 Simplified Chinese	gb2312_chinese_ci	2
gbk	GBK Simplified Chinese	gbk_chinese_ci	2
geostd8	GEOSTD8 Georgian	geostd8_general_ci	1
greek	ISO 8859-7 Greek	greek_general_ci	1
hebrew	ISO 8859-8 Hebrew	hebrew_general_ci	1
hp8	HP West European	hp8_english_ci	1
keybcs2	DOS Kamenicky Czech-Slovak	keybcs2_general_ci	1
koi8r	KOI8-R Relcom Russian	koi8r_general_ci	1
koi8u	KOI8-U Ukrainian	koi8u_general_ci	1
latin1	cp1252 West European	latin1_swedish_ci	1
latin2	ISO 8859-2 Central European	latin2_general_ci	1

Charset	Description	Default collation	Maxlen
latin5	ISO 8859-9 Turkish	latin5_turkish_ci	1
latin7	ISO 8859-13 Baltic	latin7_general_ci	1
macce	Mac Central European	macce_general_ci	1
macroman	Mac West European	macroman_general_ci	1
sjis	Shift-JIS Japanese	sjis_japanese_ci	2
swe7	7bit Swedish	swe7_swedish_ci	1
tis620	TIS620 Thai	tis620_thai_ci	1
ucs2	UCS-2 Unicode		2
ujis	EUC-JP Japanese	ujis_japanese_ci	3
utf8	UTF-8 Unicode	utf8_general_ci	3/4 (see OLD_MODE)
utf16	UTF-16 Unicode		4
utf16le	UTF-16LE Unicode	utf16le_general_ci	4
utf32	UTF-32 Unicode	utf32_general_ci (<= MariaDB 11.4) utf32_uca1400_ai_ci (>=MariaDB 11.5)	4
utf8mb3	UTF-8 Unicode	utf8mb3_general_ci (<= MariaDB 11.4) utf8mb3_uca1400_ai_ci (>=MariaDB 11.5)	3
utf8mb4	UTF-8 Unicode	utf8mb4_general_ci (<= MariaDB 11.4) utf8mb4_uca1400_ai_ci (>=MariaDB 11.5)	4

Warning:

Note that the Mroonga Storage Engine only supports a limited number of character sets. See Mroonga's available character sets.

Collations

MariaDB supports the following collations (from MariaDB 11.4.5):

```
SELECT collation_name, character_set_name as cs_name, id, is_default AS def, is_compiled AS com,
  sortlen, comment FROM information_schema.collations ORDER BY collation_name;
+--------------------------------+----------+------+------+-----+---------+-----------------------------
--------------------+
| collation_name                 | cs_name  | id   | def  | com | sortlen | comment
|
+--------------------------------+----------+------+------+-----+---------+-----------------------------
--------------------+
| armscii8_bin                   | armscii8 |   64 |      | Yes |       1 | ARMSCII-8 Armenian
|
| armscii8_general_ci            | armscii8 |   32 | Yes  | Yes |       1 | ARMSCII-8 Armenian
|
| armscii8_general_nopad_ci      | armscii8 | 1056 |      | Yes |       1 | ARMSCII-8 Armenian
|

+--------------------------------+----------+------+------+-----+---------+-----------------------------
--------------------+
550 rows in set (0.005 sec)
```

:information_source: The UCA-14.0.0 collations were added in MariaDB 10.10.1.

:information_source: Before MariaDB 10.6.1, the `utf8mb3*` collations listed above were named `utf8*`.

:information_source: MariaDB 11.4.5 added UCA-9.0.0 collations, as well as a Comment column to `information_schema.collations`, to make it clear that the UCA-9.0.0 collations are mapped to the UCA-14.0.0 collations. The UCA-9.0.0 collations have mainly been added to make it easy to replicate from MySQL 8.0 to MariaDB 11.4.5 and newer.

> **Note:**
>
> Note that some of the collations are used with several different character sets. In this case, the `Charset` and `Id` columns are `NULL`.

You can find all combinations of the supported character set and collation in the information_schema.COLLATION_CHARACTER_SET_APPLICABILITY table.

Case Sensitivity

A '`ci`' at the end of a collation name indicates the collation is case-insensitive. A '`cs`' at the end of a collation name indicates the collation is case sensitive.

NO PAD Collations

`NO PAD` collations regard trailing spaces as normal characters. You can get a list of all of these by querying the Information Schema COLLATIONS Table as follows:

```
SELECT collation_name FROM information_schema.COLLATIONS
WHERE collation_name LIKE "%nopad%";
+------------------------------+
| collation_name               |
+------------------------------+
| big5_chinese_nopad_ci        |
| big5_nopad_bin               |
...
```

Accent Insensitivity

An accent insensitive collation is one where the accented and unaccented versions of a letter are considered to be identical for sorting purposes.

:information_source: MariaDB 10.10 added the accent insensitivity flag, and new collations are marked with '_ai' or '_as' in the name to indicate this, for example:

```
...
| uca1400_spanish2_ai_ci         |
| uca1400_spanish2_ai_cs         |
| uca1400_spanish2_as_ci         |
| uca1400_spanish2_as_cs         |
...
```

Changes

- MariaDB 10.10 added 184 UCA-14.0.0 collations. Unicode-14.0.0 was released in September 2021. They contain 939 built-in contractions. Old collations based on UCA-4.0.0 and UCA-5.2.0 did not support built-in contractions. This is a step towards better Unicode Collation Algorithm compliance. With built-in contractions, some languages (e.g., Thai) won't need specific collations and will just work with the default "root" collation.
- MariaDB 10.6.1 changed the `utf8` character set by default to be an alias for utf8mb3 rather than the other way around. It can be set to imply `utf8mb4` by changing the value of the old_mode system variable.
- MariaDB 10.2.2 added 88 `NO PAD` collations.
- MariaDB 10.1.15 added the `utf8_thai_520_w2`, `utf8mb4_thai_520_w2`, `ucs2_thai_520_w2`, `utf16_thai_520_w2` and `utf32_thai_520_w2` collations.
- MariaDB 10.0.7 added the `utf8_myanmar_ci`, `ucs2_myanmar_ci`, `utf8mb4_myanmar_ci`, `utf16_myanmar_ci` and `utf32_myanmar_ci` collations.
- MariaDB 10.0.5 added the `utf8_german2_ci`, `utf8mb4_german2_ci`, `ucs2_german2_ci`, `utf16_german2_ci` and `utf32_german2_ci` collations.
- MariaDB 5.1.41 added a Croatian collation patch from Alexander Barkov to fix some problems with the Croatian character set and `LIKE` queries. This patch added `utf8_croatian_ci` and `ucs2_croatian_ci` collations to MariaDB.

Unicode

Unicode is a standard for encoding text across multiple writing systems. MariaDB supports a number of character sets for storing Unicode data:

Character Set	Description
`ucs2`	UCS-2, each character is represented by a 2-byte code with the most significant byte first. Fixed-length 16-bit encoding.
`utf8`	`utf8` is an alias for `utf8mb3`, but this can changed to `ut8mb4` by changing the default value of the old_mode system variable.
`utf8mb3`	UTF-8 encoding using one to three bytes per character. Basic Latin letters, numbers and punctuation use one byte. European and Middle East letters mostly fit into 2 bytes. Korean, Chinese, and Japanese ideographs use 3-bytes. No supplementary characters are stored. Until MariaDB 10.5, this was an alias for utf8. From MariaDB 10.6, utf8 is by default an alias for utf8mb3, but this can changed to ut8mb4 by changing the default value of the old_mode system variable.
`utf8mb4`	UTF-8 encoding the same as `utf8mb3` but which stores supplementary characters in four bytes.
`utf16`	UTF-16, same as `ucs2`, but stores supplementary characters in 32 bits. 16 or 32-bits.
`utf32`	UTF-32, fixed-length 32-bit encoding.

Support for the UCA-14.0.0 collations was added in MariaDB 10.10 (MDEV-27009).

Support for the MySQL 8.0 UCA-9-0-0 (utf8mb4_0900_…) collations will be added to MariaDB 11.4.5.

Internationalization and Localization

See Coordinated Universal Time.

Coordinated Universal Time (UTC) is the primary time standard by which the world regulates clocks and time, and is the internal storage format for MariaDB timestamp values.

See Locales Plugin.

The LOCALES plugin enables the INFORMATION_SCHEMA.LOCALES table and SHOW LOCALES statement, allowing users to view all locales compiled into the server.

See Server Locale.

Server locale settings control the language for date and time functions via lc_time_names and the language for error messages via lc_messages.

See Setting the Language for Error Messages.

Learn how to configure the lc_messages and lc_messages_dir system variables to display server error messages in a supported local language.

See Time Zones.

How MariaDB tracks and converts time zone settings, including named time zones, the time-zone system tables, and per-session configuration.

This page is licensed: CC BY-SA / Gnu FDL

Coordinated Universal Time

UTC stands for Coordinated Universal Time. It is the world standard for regulating time.

MariaDB stores values internally in UTC, converting them to the required time zone as required.

In general terms it is equivalent to Greenwich Mean Time (GMT), but UTC is used in technical contexts, as it is precisely defined at the subsecond level.

Time zones are offset relative to UTC. For example, time in Tonga is UTC + 13, so 03h00 UTC is 16h00 in Tonga.

Locales Plugin

The `LOCALES` plugin creates the LOCALES table in the INFORMATION_SCHEMA database. The plugin also adds the SHOW LOCALES statement.The table and statement can be queried to see all locales that are compiled into the server.

Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN. For example:

```
INSTALL SONAME 'locales';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the –plugin-load or the –plugin-load-add options. This can be specified as a command-line argument to mysqld or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_load_add = locales
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN. For example:

```
UNINSTALL SONAME 'locales';
```

If you installed the plugin by providing the –plugin-load or the –plugin-load-add options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Example

```
SELECT * FROM INFORMATION_SCHEMA.LOCALES;
+-----+-------+-----------------------------------+----------------------+--------------------+------

```

Options

`locales`

- Description: Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server still continues starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server fails to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server fails to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- Command line: `--locales=value`
- Data Type: `enumerated`
- Default Value: `ON`
- Valid Values: `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

Server Locale

The lc_time_names server system variable sets the language used by the date and time functions DAYNAME(), MONTHNAME(), and DATE_FORMAT(), and the lc_messages sets the language for error messages.

The list of the locales supported by the current MariaDB installation can be obtained via the LOCALES plugin.

MariaDB supports the following locale values:

Locale	Language	Territory
ar_AE	Arabic	United Arab Emirates
ar_BH	Arabic	Bahrain
ar_DZ	Arabic	Algeria
ar_EG	Arabic	Egypt
ar_IN	Arabic	Iran
ar_IQ	Arabic	Iraq
ar_JO	Arabic	Jordan
ar_KW	Arabic	Kuwait
ar_LB	Arabic	Lebanon
ar_LY	Arabic	Libya
ar_MA	Arabic	Morocco
ar_OM	Arabic	Oman
ar_QA	Arabic	Qatar
ar_SA	Arabic	Saudi Arabia
ar_SD	Arabic	Sudan
ar_SY	Arabic	Syria
ar_TN	Arabic	Tunisia

Locale	Language	Territory
ar_YE	Arabic	Yemen
be_BY	Belarusian	Belarus

uk_UA	Ukrainian	Ukraine
ur_PK	Urdu	Pakistan
vi_VN	Vietnamese	Viet Name
zh_CN	Chinese	China
zh_HK	Chinese	Hong Kong
zh_TW	Chinese	Taiwan Province of China

Examples

Setting the lc_time_names and lc_messages variables to localize the units of date and time, and the server error messages.

```
SELECT DAYNAME('2013-04-01'), MONTHNAME('2013-04-01');
+----------------------+------------------------+
| DAYNAME('2013-04-01') | MONTHNAME('2013-04-01') |
+----------------------+------------------------+
| Monday                | April                  |
+----------------------+------------------------+

SET lc_time_names = 'fr_CA';

SELECT DAYNAME('2013-04-01'), MONTHNAME('2013-04-01');
+----------------------+------------------------+
| DAYNAME('2013-04-01') | MONTHNAME('2013-04-01') |
+----------------------+------------------------+
| lundi                 | avril                  |
+----------------------+------------------------+

SELECT blah;
ERROR 1054 (42S22): Unknown column 'blah' in 'field' list'

SET lc_messages = 'nl_NL';

SELECT blah;
ERROR 1054 (42S22): Onbekende kolom 'blah' in field list
```

This page is licensed: CC BY-SA / Gnu FDL

Setting the Language for Error Messages

MariaDB server error messages are by default in English. However, MariaDB server also supports error message localization in many different languages. Each supported language has its own version of the error message file called `errmsg.sys` in a dedicated directory for that language.

Supported Languages for Error Messages

Error message localization is supported for the following languages:

- Bulgarian
- Chinese (from MariaDB 10.4.25, 10.5.16, 10.6.8, 10.7.4, 10.8.3)
- Czech
- Danish
- Dutch
- English
- Estonian
- French
- Georgian (from MariaDB 10.11.3)
- German
- Greek
- Hindi
- Hungarian
- Italian
- Japanese
- Korean
- Norwegian
- Norwegian-ny (Nynorsk)
- Polish
- Portuguese
- Romanian
- Russian
- Serbian
- Slovak
- Spanish
- Swahili (from MariaDB 11.1.2)
- Swedish
- Ukrainian

Setting the `lc_messages` and `lc_messages_dir` System Variables

The lc_messages and lc_messages_dir system variables can be used to set the server locale used for error messages.

The lc_messages system variable can be specified as a locale name. The language of the associated locale will be used for error messages. See Server Locales for a list of supported locales and their associated languages.

The lc_messages system variable is set to `en_US` by default, which means that error messages are in English by default.

If the lc_messages system variable is set to a valid locale name, but the server can't find an error message file for the language associated with the locale, then the default language will be used instead.

This system variable can be specified as command-line arguments to mariadbd or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
lc_messages=fr_CA
```

The lc_messages system variable can also be changed dynamically with SET GLOBAL. For example:

```
SET GLOBAL lc_messages='fr_CA';
```

If a server has the lc_messages system variable set to the `fr_CA` locale like the above example, then error messages would be in French. For example:

```
SELECT blah;
ERROR 1054 (42S22): Champ 'blah' inconnu dans field list
```

The lc_messages_dir system variable can be specified either as the path to the directory storing the server's error message files or as the path to the directory storing the specific language's error message file.

The server initially tries to interpret the value of the lc_messages_dir system variable as a path to the directory storing the server's error message files. Therefore, it constructs the path to the language's error message file by concatenating the value of the lc_messages_dir system variable with the language name of the locale specified by the lc_messages system variable .

If the server does not find the error message file for the language, then it tries to interpret the value of the lc_messages_dir system variable as a direct path to the directory storing the specific language's error message file.

This system variable can be specified as command-line arguments to mariadbd or it can be specified in a relevant server option group in an option file.

For example, to specify the path to the directory storing the server's error message files:

```
[mariadb]
...
lc_messages_dir=/usr/share/mysql/
```

Or to specify the path to the directory storing the specific language's error message file:

```
[mariadb]
...
lc_messages_dir=/usr/share/mysql/french/
```

The lc_messages_dir system variable can not be changed dynamically.

Setting the –language Option

The –language option can also be used to set the server's language for error messages, but it is deprecated. It is recommended to set the lc_messages system variable instead.

The –language option can be specified either as a language name or as the path to the directory storing the language's error message file. See Server Locales for a list of supported locales and their associated languages.

This option can be specified as command-line arguments to mariadbd or it can be specified in a relevant server option group in an option file.

For example, to specify a language name:

```
[mariadb]
...
language=french
```

Or to specify the path to the directory storing the language's error message file:

```
[mariadb]
...
language=/usr/share/mysql/french/
```

Character Set

The character set that the error messages are returned in is determined by the character_set_results variable, which defaults to UTF8.

This page is licensed: CC BY-SA / Gnu FDL

Time Zones

MariaDB keeps track of several time zone settings.

Setting the Time Zone

The time_zone system variable is the primary way to set the time zone. It can be specified in one of the following formats:

- The default value is `SYSTEM`, which indicates that the system time zone defined in the system_time_zone system variable will be used. Note that if you are using `SYSTEM` with replication in either statement or mixed mode, you MUST use the same value for `system_time_zone` on all replicas (otherwise `TIMESTAMP` columns will not replicate correctly). See System Time Zone below for more information.
- An offset from Coordinated Universal Time (UTC), such as `+5:00` or `-9:00`, can also be used.
- If the time zone tables in the mysql database were loaded, then a named time zone, such as `America/New_York`, `Africa/Johannesburg`, or `Europe/Helsinki`, is also permissible. See mysql Time Zone Tables below for more information.

There are two time zone settings that can be set within MariaDB–the global server time zone, and the time zone for your current session. There is also a third time zone setting which may be relevant–the system time zone.

Global Server Time Zone

The global server time zone can be changed at server startup by setting the `--default-time-zone` option either on the command-line or in a server option group in an option file. For example:

```
[mariadb]
...
default_time_zone = 'America/New_York'
```

The global server time zone can also be changed dynamically by setting the time_zone system variable as a user account that has the SUPER privilege. For example:

```
SET GLOBAL time_zone = 'America/New_York';
```

The current global server time zone can be viewed by looking at the global value of the time_zone system variable. For example:

```
SHOW GLOBAL VARIABLES LIKE 'time_zone';
+---------------+--------+
| Variable_name | Value  |
+---------------+--------+
| time_zone     | SYSTEM |
+---------------+--------+
```

Session Time Zone

Each session that connects to the server will also have its own time zone. This time zone is initially inherited from the global value of the time_zone system variable, which sets the session value of the same variable.

A session's time zone can be changed dynamically by setting the time_zone system variable. For example:

```
SET time_zone = 'America/New_York';
```

The current session time zone can be viewed by looking at the session value of the time_zone system variable. For example:

```
SHOW SESSION VARIABLES LIKE 'time_zone';
+---------------+--------+
| Variable_name | Value  |
+---------------+--------+
| time_zone     | SYSTEM |
+---------------+--------+
```

System Time Zone

The system time zone is determined when the server starts, and it sets the value of the system_time_zone system variable. The system time zone is usually read from the operating system's environment. You can change the system time zone in several different ways, such as:

- If you are starting the server with mariadbd-safe, then you can set the system time zone with the `--timezone` option either on the command-line or in the [mariadbd-safe] option group in an option file. For example:

```
[mariadbd-safe]
timezone='America/New_York'
```

- If you are using a Unix-like operating system, then you can set the system time zone by setting the `TZ` environment variable in your shell before starting the server. For example:

```
$ export TZ='America/New_York'
$ service mariadb start
```

- On some Linux operating systems, you can change the default time zone for the whole system by making the /etc/localtime symbolic link point to the desired time zone. For example:

```
$ sudo rm /etc/localtime
$ sudo ln -s /usr/share/zoneinfo/America/New_York /etc/localtime
```

- On some Debian-based Linux operating systems, you can change the default time zone for the whole system by executing the following:

```
sudo dpkg-reconfigure tzdata
```

- On Linux operating systems that use systemd, you can change the default time zone for the whole system by using the timedatectl utility. For example:

```
sudo timedatectl set-timezone America/New_York
```

Time Zone Effects

Time Zone Effects on Functions

Some functions are affected by the time zone settings. These include:

- NOW()
- SYSDATE()
- CURDATE()
- CURTIME()
- UNIX_TIMESTAMP()

Some functions are not affected. These include:

- UTC_DATE()
- UTC_TIME()
- UTC_TIMESTAMP()

Time Zone Effects on Data Types

Some data types are affected by the time zone settings.

- TIMESTAMP - See TIMESTAMP: Time Zones for information on how this data type is affected by time zones.
- DATETIME - See DATETIME: Time Zones for information on how this data type is affected by time zones.

mysql Time Zone Tables

The mysql database contains a number of time zone tables:

- time_zone
- time_zone_leap_second
- time_zone_name
- time_zone_transition
- time_zone_transition_type

By default, these time zone tables in the mysql database are created, but not populated.

If you are using a Unix-like operating system, then you can populate these tables using the mariadb-tzinfo-to-sql utility, which uses the zoneinfo data available on Linux, Mac OS X, FreeBSD and Solaris.

If you are using Windows, then you will need to import pre-populated time zone tables. These are available at MariaDB mirrors.

Time zone data needs to be updated on occasion. When that happens, the time zone tables may need to be reloaded.

Plugins

See Plugin Overview.

MariaDB supports loading plugins at startup or runtime to extend functionality, including storage engines, security features, and logging capabilities, without rebuilding the server.

See Plugin Maturity.

This page lists the maturity level (Alpha, Beta, Gamma, Stable) of various MariaDB plugins, helping users determine which are suitable for production environments.

See Storage Engines.

Every MariaDB storage engine is implemented as a plugin. This section covers them all, from InnoDB and Aria to Spider, S3, and CONNECT.

See MariaDB Enterprise Audit.

The MariaDB Enterprise Audit plugin logs detailed data access and configuration changes, offering advanced filtering to meet security and compliance requirements.

See MariaDB Community Audit Plugin.

Complete MariaDB Audit Plugin reference: server_audit activity logging, connection/query event tracking, file/syslog output, and compliance configuration.

See Authentication Plugins.

Explore the authentication plugins available in MariaDB, such as ed25519, GSSAPI, and PAM, which provide flexible and secure methods for user verification.

See MariaDB Replication & Cluster Plugins.

This section covers plugins specifically designed for high availability and clustering, including the wsrep_provider plugin used for Galera Cluster integration.

See Other Plugins.

Discover additional plugins that extend MariaDB Server functionality, such as the Disks, Feedback, and Query Response Time plugins, for specialized use cases.

See Password Validation Plugins.

Password validation plugins, like simple_password_check and cracklib, enforce strong password policies by checking new passwords against defined complexity rules.

This page is licensed: CC BY-SA / Gnu FDL

Plugin Overview

MariaDB supports the use of plugins, software components that may be added to the core software without having to rebuild the MariaDB server from source code. Plugins can be loaded at startup, or loaded and unloaded while the server is running, without interruption. Plugins are commonly used for adding desired storage engines, additional security requirements, logging special information about the server, or even small enhancements, such as a plugin to get a timestamp as an integer.

Querying Plugin Information

There are a number of ways to see which plugins are currently active.

A server almost always has a large number of active plugins, because the server contains a large number of built-in plugins, which are active by default and cannot be uninstalled.

Querying Plugin Information with `SHOW PLUGINS`

The SHOW PLUGINS statement can be used to query information about all active plugins.

For example:

```
SHOW PLUGINS\G;
*********************** 1. row ***********************
   Name: binlog
 Status: ACTIVE
   Type: STORAGE ENGINE
Library: NULL
License: GPL
*********************** 2. row ***********************
   Name: mysql_native_password
 Status: ACTIVE
   Type: AUTHENTICATION
Library: NULL
License: GPL
*********************** 3. row ***********************
   Name: mysql_old_password
 Status: ACTIVE
   Type: AUTHENTICATION
Library: NULL
License: GPL
...
```

If a plugin's `Library` column has a `NULL` value, then the plugin is built-in, and it cannot be uninstalled.

Querying Plugin Information with information_schema.PLUGINS

The information_schema.PLUGINS table can be queried to get more detailed information about plugins.

For example:

```
SELECT * FROM information_schema.PLUGINS\G
...
*************************** 65. row ***************************
           PLUGIN_NAME: user_variables
        PLUGIN_VERSION: 1.0
         PLUGIN_STATUS: ACTIVE
           PLUGIN_TYPE: INFORMATION SCHEMA
   PLUGIN_TYPE_VERSION: 110600.0
        PLUGIN_LIBRARY: NULL
PLUGIN_LIBRARY_VERSION: NULL
         PLUGIN_AUTHOR: Sergey Vojtovich
    PLUGIN_DESCRIPTION: User-defined variables
        PLUGIN_LICENSE: GPL
           LOAD_OPTION: ON
       PLUGIN_MATURITY: Stable
   PLUGIN_AUTH_VERSION: 1.0
*************************** 66. row ***************************
           PLUGIN_NAME: wsrep_provider
        PLUGIN_VERSION: 1.0
         PLUGIN_STATUS: ACTIVE
           PLUGIN_TYPE: REPLICATION
   PLUGIN_TYPE_VERSION: 2.0
        PLUGIN_LIBRARY: NULL
PLUGIN_LIBRARY_VERSION: NULL
         PLUGIN_AUTHOR: Codership Oy
    PLUGIN_DESCRIPTION: Wsrep provider plugin
        PLUGIN_LICENSE: GPL
           LOAD_OPTION: ON
       PLUGIN_MATURITY: Alpha
   PLUGIN_AUTH_VERSION: 1.0
*************************** 67. row ***************************
           PLUGIN_NAME: THREAD_POOL_GROUPS
        PLUGIN_VERSION: 1.0
         PLUGIN_STATUS: ACTIVE
           PLUGIN_TYPE: INFORMATION SCHEMA
   PLUGIN_TYPE_VERSION: 110600.0
        PLUGIN_LIBRARY: NULL
PLUGIN_LIBRARY_VERSION: NULL
         PLUGIN_AUTHOR: Vladislav Vaintroub
    PLUGIN_DESCRIPTION: Provides information about threadpool groups.
        PLUGIN_LICENSE: GPL
           LOAD_OPTION: ON
       PLUGIN_MATURITY: Stable
   PLUGIN_AUTH_VERSION: 1.0
...
```

If a plugin's `PLUGIN_LIBRARY` column has the `NULL` value, the plugin is built-in and cannot be uninstalled.

Querying Plugin Information with `mysql.plugin`

The mysql.plugin table can be queried to get information about installed plugins.

This table only contains information about plugins that have been installed via the following methods:

- The INSTALL SONAME statement.
- The INSTALL PLUGIN statement.
- The mariadb-plugin utility.

This table does not contain information about:

- Built-in plugins.
- Plugins loaded with the –plugin-load-add option.
- Plugins loaded with the –plugin-load option.

This table only contains enough information to reload the plugin when the server is restarted, which means it only contains the plugin name and the plugin library.

For example:

```
SELECT * FROM mysql.plugin;

+------+------------+
| name | dl         |
+------+------------+
| PBXT | libpbxt.so |
+------+------------+
```

Installing a Plugin

There are three primary ways to install a plugin:

- A plugin can be installed dynamically with an SQL statement.
- A plugin can be installed with a mariadbd option, but it requires a server restart.
- A plugin can be installed with the mariadb-plugin utility, while the server is completely offline.

When you are installing a plugin, you also have to ensure that:

- The server's plugin directory is properly configured, and the plugin's library is in the plugin directory.
- The server's minimum plugin maturity is properly configured, and the plugin is mature enough to be installed.

Installing a Plugin Dynamically

A plugin can be installed dynamically by executing either the INSTALL SONAME or the INSTALL PLUGIN statement.

If a plugin is installed with one of these statements, a record will be added to the mysql.plugins table for the plugin. This means that the plugin will automatically be loaded every time the server restarts, unless specifically uninstalled or deactivated.

Installing a Plugin with `INSTALL SONAME`

You can install a plugin dynamically by executing the INSTALL SONAME statement. INSTALL SONAME installs all plugins from the given plugin library. This could be required for some plugin libraries.

For example, to install all plugins in the `server_audit` plugin library (which is currently only the server_audit audit plugin), you could execute the following:

```
INSTALL SONAME 'server_audit';
```

Installing a Plugin with `INSTALL PLUGIN`

You can install a plugin dynamically by executing the INSTALL PLUGIN statement. INSTALL PLUGIN installs a single plugin from the given plugin library.

For example, to install the server_audit audit plugin from the `server_audit` plugin library, you could execute the following:

```
INSTALL PLUGIN server_audit SONAME 'server_audit';
```

Installing a Plugin with Plugin Load Options

A plugin can be installed with a mariadbd option by providing either the –plugin-load-add or the –plugin-load option.

If a plugin is installed with one of these options, then a record will **not** be added to the mysql.plugins table for the plugin. This means that if the server is restarted without the same option set, then the plugin will **not** automatically be loaded.

Installing a Plugin with `--plugin-load-add`

You can install a plugin with the –plugin-load-add option by specifying the option as a command-line argument to mariadbd or by specifying the option in a relevant server option group in an option file.

The `--plugin-load-add` option uses the following format:

- Plugins can be specified in the format `name=library`, where `name` is the plugin name and `library` is the plugin library. This format installs a single plugin from the given plugin library.
- Plugins can also be specified in the format `library`, where `library` is the plugin library. This format installs all plugins from the given plugin library.
- Multiple plugins can be specified by separating them with semicolons.

For example, to install all plugins in the `server_audit` plugin library (which is currently only the server_audit audit plugin) and also the ed25519 authentication plugin from the `auth_ed25519` plugin library, you could set the option to the following values on the command-line:

```
$ mariadbd --user=mysql --plugin-load-add='server_audit' --plugin-load-add='ed25519=auth_ed25519'
```

You could also set the option to the same values in an option file:

```
[mariadb]
...
plugin_load_add = server_audit
plugin_load_add = ed25519=auth_ed25519
```

Special care must be taken when specifying both the –plugin-load option and the –plugin-load-add option together. The `--plugin-load` option resets the plugin load list, and this can cause unexpected problems if you are not aware. The `--plugin-load-add` option does **not** reset the plugin load list, so it is much safer to use. See Specifying Multiple Plugin Load Options for more information.

Installing a Plugin with `--plugin-load`

You can install a plugin with the –plugin-load option by specifying the option as a command-line argument to mariadbd or by specifying the option in a relevant server option group in an option file.

The `--plugin-load` option uses the following format:

- Plugins can be specified in the format `name=library`, where `name` is the plugin name and `library` is the plugin library. This format installs a single plugin from the given plugin library.
- Plugins can also be specified in the format `library`, where `library` is the plugin library. This format installs all plugins from the given plugin library.
- Multiple plugins can be specified by separating them with semicolons.

For example, to install all plugins in the `server_audit` plugin library (which is currently only the server_audit audit plugin) and also the ed25519 authentication plugin from the `auth_ed25519` plugin library, you could set the option to the following values on the command-line:

```
$ mariadbd --user=mysql --plugin-load='server_audit;ed25519=auth_ed25519'
```

You could also set the option to the same values in an option file:

```
[mariadb]
...
plugin_load = server_audit;ed25519=auth_ed25519
```

Special care must be taken when specifying the `--plugin-load` option multiple times, or when specifying both the –plugin-load option and the `--plugin-load-add` option together. The `--plugin-load` option resets the plugin load list, and this can cause unexpected problems if you are not aware. The `--plugin-load-add` option does **not** reset the plugin load list, so it is much safer to use. See Specifying Multiple Plugin Load Options for more information.

Specifying Multiple Plugin Load Options

Special care must be taken when specifying the `--plugin-load` option multiple times, or when specifying both the `--plugin-load` option and the -`-plugin-load-add` option. The `--plugin-load` option resets the plugin load list, and this can cause unexpected problems if you are not aware. The `--plugin-load-add` option does **not** reset the plugin load list, so it is much safer to use.

This can have the following consequences:

- If the `--plugin-load` option is specified multiple times, then only the last instance will have any effect. For example, in the following case, the first instance of the option is reset:

```
[mariadb]
...
plugin_load = server_audit
plugin_load = ed25519=auth_ed25519
```

- If the –plugin-load option is specified after the `--plugin-load-add` option, then it will also reset the changes made by that option. For example, in the following case, the `--plugin-load-add` option does not do anything, because the subsequent `--plugin-load` option resets the plugin load list:

```
[mariadb]
...
plugin_load_add = server_audit
plugin_load = ed25519=auth_ed25519
```

- In contrast, if the `--plugin-load` option is specified before the `--plugin-load-add` option, then it will work fine, because the `--plugin-load-add` option does not reset the plugin load list. For example, in the following case, both plugins are properly loaded:

```
[mariadb]
...
plugin_load = server_audit
plugin_load_add = ed25519=auth_ed25519
```

Installing a Plugin with mariadb-plugin

A plugin can be installed with the mariadb-plugin utility if the server is completely offline.

The syntax is:

```
mariadb-plugin [options] <plugin> ENABLE|DISABLE
```

For example, to install the server_audit audit plugin, you could execute the following:

```
mariadb-plugin server_audit ENABLE
```

If a plugin is installed with this utility, a record will be added to the mysql.plugins table for the plugin. This means that the plugin will automatically be loaded every time the server restarts, unless specifically uninstalled or deactivated.

Configuring the Plugin Directory

When a plugin is being installed, the server looks for the plugin's library in the server's plugin directory. This directory is configured by the `plugin_dir` system variable. This can be specified as a command-line argument to mariadbd or it can be specified in a relevant server option group in an option file:

```
[mariadb]
...
plugin_dir = /usr/lib64/mysql/plugin
```

Configuring the Minimum Plugin Maturity

When a plugin is being installed, the server compares the plugin's maturity level against the server's minimum allowed plugin maturity. This can help prevent users from using unstable plugins on production servers. This minimum plugin maturity is configured by the plugin_maturity system variable. This can be specified as a command-line argument to mariadbd or it can be specified in a relevant server option group in an option file:

```
[mariadb]
...
plugin_maturity = stable
```

Configuring Plugin Activation at Server Startup

A plugin will be loaded by default when the server starts if:

- The plugin was installed with the INSTALL SONAME statement.
- The plugin was installed with the INSTALL PLUGIN statement.
- The plugin was installed with the mariadb-plugin utility.
- The server is configured to load the plugin with the –plugin-load-add option.
- The server is configured to load the plugin with the –plugin-load option.

This behavior can be changed with special options that take the form `--plugin-name`. For example, for the server_audit audit plugin, the special option is called –server-audit.

The possible values for these special options are:

Option Value	Description
OFF	Disables the plugin without removing it from the mysql.plugins table.
ON	Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
FORCE	Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
FORCE_PLUS_PERMANENT	Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.

A plugin's status can be found by looking at the `PLUGIN_STATUS` column of the information_schema.PLUGINS table.

Uninstalling Plugins

Plugins that are found in the mysql.plugin table, that is those that were installed with INSTALL SONAME, INSTALL PLUGIN or mariadb-plugin can be uninstalled in one of two ways:

- The UNINSTALL SONAME or the UNINSTALL PLUGIN statement while the server is running
- With mariadb-plugin while the server is offline.

Plugins that were enabled as a `--plugin-load` option do not need to be uninstalled. If `--plugin-load` is omitted the next time the server starts, or the plugin is not listed as one of the `--plugin-load` entries, the plugin will not be

loaded.

UNINSTALL PLUGIN uninstalls a single installed plugin, while UNINSTALL SONAME uninstalls all plugins belonging to a given library.

Plugin Maturity

The following table lists the various plugins included in MariaDB ordered by their maturity. Note that maturity will differ across MariaDB versions - see below for an easy way to get a complete list of plugins and their maturity in your version of MariaDB:

Plugin	Version	Maturity
Archive	3.0	Stable
Aria	1.6	Stable
Audit Plugin	1.4	Stable
aws_key_management	1.0	Stable
binlog	2.0	Stable
Blackhole	1.0	Stable
Connect	1.7	Stable
CLIENT_STATISTICS	2.0	Stable
cracklib_password_check	1.0	Stable
CSV	1.0	Stable
DECLARE BY / associative array	1.0	Gamma
DISKS	1.1	Stable
ed25519	1.1	Stable
FederatedX	2.1	Stable
Feedback	1.1	Stable
file_key_management	2.0	Gamma
gssapi	1.0	Stable
INDEX_STATISTICS	2.0	Stable
INET4	1.0	Gamma
INET6	1.0	Stable
InnoDB	10.*	Stable
LOCALES	1.0	Stable

Plugin	Version	Maturity
Memory	1.0	Stable
METADATA_LOCK_INFO	0.1	Stable
mhnsw	1.0	Stable
MRG_MyISAM	1.0	Stable
Mroonga	7.7	Stable
MyISAM	1.0	Stable
MyRocks	1.0	Stable
mysql_json	0.1	Stable
mysql_native_password	1.0	Stable
mysql_old_password	1.0	Stable
named_pipe	1.0	Stable
online_alter_log	2.0	Stable
pam	1.0	Stable
password_reuse_check	2.0	Stable (introduced in 10.10.2, 10.9.5, and 10.8.7)
`partition`	1.0	Stable
Performance_Schema	0.1	Stable
QUERY_CACHE_INFO	1.1	Stable
query_response_time	1.0	Stable
S3	1.0	Stable
semisync	1.0	Stable
Sequence	1.0	Stable
SERVER_AUDIT	2.6	Stable
simple_password_check	1.0	Stable
Spider	3.3	Stable
SQL_ERROR_LOG	1.0	Stable
SYS_REFCURSOR	1.0	Gamma
TABLE_STATISTICS	2.0	Stable
USER_STATISTICS	2.0	Stable
user_variables	1.0	Stable
TokuDB	4.0	Stable (removed in 10.6)
unix_socket	1.1	Stable
UUID	1.0	Stable (introduced in 10.9.1)
uuid_v4	1.0	Stable
uuid_v7	1.0	Stable
wsrep	1.0	Stable
wsrep_connections	1.0	Stable
WSREP_INFO	1.0	Stable

Plugin	Version	Maturity
wsrep_provider	1.0	Stable
wsrep_thd_info	1.0	Stable
OQGraph	3.0	Gamma
Sphinx	2.0	Gamma
Columnstore	1.0	Beta
handlersocket	1.0	Beta
Cassandra	0.1	Experimental (removed in 10.6)
debug_key_management	1.0	Experimental
example_key_management	1.0	Experimental

This query shows a complete list of plugins and their maturity level:

```
SELECT plugin_name, plugin_version, plugin_maturity
FROM information_schema.plugins
ORDER BY plugin_name;
```

Plugin Support and Maintenance

Plugin maturity is not the same as plugin support and maintenance. When a plugin has a maturity level of *Stable*, that doesn't necessarily imply that it's actively maintained or supported via MariaDB Support.

Currently, the plugins maintained and supported by MariaDB plc for a given release series are the ones included in the corresponding MariaDB Enterprise Server release. Plugins that are not supported by MariaDB plc are either placed in a separate **unsupported repository** (reached by passing the `--include-unsupported` flag to the `mariadb_es_repo_setup` script) or omitted from the build entirely.

MariaDB Enterprise Audit

Overview

While application design specifications and database configurations may intend specific limitations to be placed around access to data, audit mechanisms help confirm the effectiveness of these controls.

MariaDB Enterprise Audit is a plugin that logs data access and database operations.

Audit mechanisms are most effective when they produce a manageable quantity of output. MariaDB Enterprise Audit includes advanced filtering features to enable narrowly defining which information is logged.

Where audit mechanisms may only be effective when control parameters can also be audited, MariaDB Enterprise Audit implements logging of configuration changes.

> **Important:**
>
> **Plugin Conflict (**MENT-316**)**
>
> The MariaDB Enterprise Audit plugin (`server_audit2.so`) is incompatible with the older server_audit.so (`v1`) plugin. Running both can cause server instability or deadlocks.
>
> *If you are a new user: You can continue reading.*
>
> *If you are migrating: You must remove the old `v1` plugin. Please go directly to the Upgrades section for complete instructions.*

Configuration Overview

MariaDB Enterprise Audit is installed and loaded by default. If you are unsure whether it is loaded on your system, you can confirm that the plugin is loaded.

To use MariaDB Enterprise Audit, the plugin must be configured: Administrators must define Audit Filters to configure what MariaDB Enterprise Audit writes to the audit log.

MariaDB Enterprise Audit supports two types of Audit Filters:

Audit Filter Type	Used For
Default Audit Filter	The Default Audit Filter is used for any user account that is not assigned a Named Audit Filter.
Named Audit Filters	Named Audit Filters are assigned to specific user accounts.

Administrators can define Audit Filters to audit log activity using multiple types of filters:

Filter Type	Used For
Event Filters	Event Filters are used to enable or disable audit logging for specific types of operations performed by the user accounts assigned to the Audit Filter.
Logging Filters	Logging Filters are used to enable or disable audit logging for the user accounts assigned to the Audit Filter.
Object Filters	Object Filters are used to enable or disable audit logging for specific databases or tables accessed by the user accounts assigned to the Audit Filter. Support for Object Filters was added in MariaDB Enterprise Server 10.6. Support for Object Filters was backported to ES 10.4.21-13 and ES 10.5.12-8.

Administrators must start audit logging.

General Operation

MariaDB Enterprise Audit performs audit logging during typical operations of MariaDB Enterprise Server:

- When a user connects, fails to connect, or disconnects, MariaDB Enterprise Audit will write a message to the audit log if the Audit Filter specifies the specific type of Connect Event.
- When a user executes a query, MariaDB Enterprise Audit will write a message to the audit log if the Audit Filter specifies the specific type of Query Event and if the queried objects are not excluded by Object Filters.
- When a query accesses a table, MariaDB Enterprise Audit will write a message to the audit log if the Audit Filter specifies the specific type of Table Event and if the table is not excluded by Object Filters.
- When a query modifies the MariaDB Enterprise Audit configuration, MariaDB Enterprise Audit will write a message to the audit log if the Audit Filter specifies the Audit Config Event.

- When a user's Audit Filter contains a Logging Filter that disables audit logging, all audit logging for the user's activity will be skipped.

MariaDB Enterprise Audit writes audit log messages either to a dedicated audit log file or to the system log (syslog), depending on configuration.

Audit log messages that correspond to a query are logged when the query completes. If a query is executed in a transaction, the audit log messages that correspond to the query are logged when the individual query completes, not when the transaction completes. If the query fails, the audit log message is logged at time of failure.

Audit Log Considerations

Care must be taken when logging data for audit to maintain alignment to business requirements. Concerns include:

- Queries should not be logged for tables containing Personally Identifiable Information (PII) or Sensitive PII (SPII) such as passwords, since audit log data is written unencrypted. Consider using Object Filters to exclude sensitive information from the audit log.
- Backup of audit data should be performed at least as frequently as database backups.
- Audit log data on database servers could be tampered with if the database server is compromised. Consider secure transmission of log data to a hardened and remote logging server.
- Where audit data is mission-critical, it should be subject to controls, data protection, data retention, and highly-available storage as are used for other mission-critical data.

Install the Audit Plugin

MariaDB Enterprise Audit comes preinstalled with MariaDB Enterprise Server, so no manual installation is required.

To verify that the plugin is installed:

1. Locate your server's plugin directory.
   - When MariaDB Enterprise Server is running, you can find the directory by checking the value of the `plugin_dir` system variable.

```
SHOW GLOBAL VARIABLES
   LIKE 'plugin_dir';
```

```
+---------------+--------------------------+
| Variable_name | Value                    |
+---------------+--------------------------+
| plugin_dir    | /usr/lib64/mysql/plugin/ |
+---------------+--------------------------+
```

2. Verify the `server_audit2.so` file—the shared library used by MariaDB Enterprise Audit—is present in your server's plugin directory.

```
$ ls -l /usr/lib64/mysql/plugin/server_audit2.so
```

```
-rwxr-xr-x. 1 root root 70432 Jul 15 19:03 /usr/lib64/mysql/plugin/server_audit2.so
```

MariaDB Enterprise Audit is bundled with all MariaDB Enterprise Server distributions (binary tarball, DEB/RPM package tarball, and DEB/RPM packages). If you do not see the `server_audit2.so` file, verify that MariaDB Enterprise Server has been installed correctly.

Load the Audit Plugin

MariaDB Enterprise Audit is enabled through the `mariadb-enterprise.cnf` configuration file, which is included by default with MariaDB Enterprise Server. This means manual loading is usually not required.

The `mariadb-enterprise.cnf` file activates MariaDB Enterprise Audit by configuring the `plugin-load-add` and `server-audit` options.

```
# -- Auditing - pre-load Plugin
plugin-load-add=server_audit
server_audit=FORCE_PLUS_PERMANENT
```

If your environment does not use `mariadb-enterprise.cnf`, you can enable MariaDB Enterprise Audit by adding the same options to your own configuration file.

Confirm the Audit Plugin is Loaded

To verify that MariaDB Enterprise Audit is installed, check the `information_schema.PLUGINS` table.

```
SELECT PLUGIN_STATUS, PLUGIN_LIBRARY, PLUGIN_DESCRIPTION, LOAD_OPTION
FROM information_schema.PLUGINS
WHERE PLUGIN_NAME='SERVER_AUDIT'\G
```

```
*************************** 1. row ***************************
     PLUGIN_STATUS: ACTIVE
    PLUGIN_LIBRARY: server_audit2.so
PLUGIN_DESCRIPTION: MariaDB Enterprise Audit
       LOAD_OPTION: FORCE_PLUS_PERMANENT
```

MariaDB Enterprise Audit is enabled through the `mariadb-enterprise.cnf` configuration file, which is included by default in MariaDB Enterprise Server. If your results differ from the example output above, verify that the `mariadb-enterprise.cnf` file specifies the `plugin-load-add` and `server-audit` options.

Start Audit Logging

When MariaDB Enterprise Audit is installed and loaded, audit logging does not begin automatically. You must explicitly start it, either from the shell or through SQL.

Interface	Method	Benefits
Shell	Configuration File	SQL access is not required SUPER privilege is not required Configuration file can be version controlled.
SQL	SET GLOBAL Statement	Server restart is not required.

Start Audit Logging in Configuration File

Enable audit logging with MariaDB Enterprise Audit by setting the `server_audit_logging` system variable in a configuration file. Alternatively, enable it dynamically with `SET GLOBAL`, which does not require a server restart.

To configure in a file:

1. Set the `server_audit_logging` system variable in the configuration file.

```
[mariadb]
server_audit_logging = ON
```

2. Restart MariaDB Enterprise Server:

```
$ sudo systemctl restart mariadb
```

If the server does not start, review the error log for details.

3. To confirm that audit logging is running, check the value of the `Server_audit_active` status variable using the `SHOW GLOBAL STATUS` statement.

```
SHOW GLOBAL STATUS
   LIKE 'Server_audit_active';
```

```
+---------------------+-------+
| Variable_name       | Value |
+---------------------+-------+
| Server_audit_active | ON    |
+---------------------+-------+
```

Start Audit Logging with SET GLOBAL

Audit logging with MariaDB Enterprise Audit can be started by setting the server_audit_logging system variable with the SET GLOBAL statement, which requires the SUPER privilege.

1. Set the server_audit_logging system variable with the SET GLOBAL statement:

```
SET GLOBAL server_audit_logging=ON;
```

2. Confirm that audit logging is started by querying the Server_audit_active status variable with the SHOW GLOBAL STATUS statement:

```
SHOW GLOBAL STATUS
   LIKE 'Server_audit_active';
```

```
+---------------------+-------+
| Variable_name       | Value |
+---------------------+-------+
| Server_audit_active | ON    |
+---------------------+-------+
```

When you modify a system variable dynamically using the `SET GLOBAL` statement, the change is not preserved after a server restart. To ensure audit logging automatically starts with the server, also configure the `server_audit_logging` system variable in a configuration file.

```
[mariadb]
server_audit_logging = ON
```

Confirm Audit Logging is Started

Confirm that audit logging is started by querying the Server_audit_active status variable with the SHOW GLOBAL STATUS statement:

```
SHOW GLOBAL STATUS
   LIKE 'Server_audit_active';
```

```
+---------------------+-------+
| Variable_name       | Value |
+---------------------+-------+
| Server_audit_active | ON    |
+---------------------+-------+
```

Audit Logging Buffer Writes

> **Note:**
>
> Buffer writes are available from MariaDB Enterprise Server 11.8.

Audit log buffering is controlled by these variables:

- `server_audit_file_buffer_size` — This defines the size of the buffer. The default value is `0`, meaning there's no buffering at all. Setting non-zero value enables the buffering with the buffer of the specified size aligned by `8192`. The maximum value is `65536`.
- `server_audit_sync_log_file` — This flushes the buffer to the log file. While the log record is in the buffer, it cannot be seen in the log file. If there aren't many events to log, the time before records can be observed can be significant. You can issue this statement to force writing the buffer to the file, making sure not to miss recent records:

```
SET GLOBAL server_audit_log_file=1
```

Forbid Uninstallation

In a secure environment, MariaDB Enterprise Audit provides administrators with an audit trail of actions performed by users on the MariaDB Enterprise Server node. To protect the integrity of the audit trail, users should not be able to uninstall MariaDB Enterprise Audit. If the server-audit option is set to `FORCE_PLUS_PERMANENT`, MariaDB Enterprise Server will prevent MariaDB Enterprise Audit from being uninstalled:

```
server_audit=FORCE_PLUS_PERMANENT
```

When a user tries to uninstall MariaDB Enterprise Audit with the server-audit option set to `FORCE_PLUS_PERMANENT`, the operation fails with the `ER_PLUGIN_IS_PERMANENT` error code:

```
UNINSTALL SONAME 'server_audit2';
```

```
ERROR 1702 (HY000): Plugin 'SERVER_AUDIT' is force_plus_permanent and can not be unloaded
```

Note:

The `mariadb-enterprise.cnf` configuration file included by default in MariaDB Enterprise Server sets the server-audit option to `FORCE_PLUS_PERMANENT`. As a consequence, MariaDB Enterprise Server forbids MariaDB Enterprise Audit from being uninstalled by default.

If you do not use `mariadb-enterprise.cnf` in your environment, you can configure MariaDB Enterprise Audit to forbid uninstallation by setting the server-audit option in your configuration file.

Confirm that Uninstallation is Forbidden

To confirm that MariaDB Enterprise Audit is configured to forbid uninstallation, query the information_schema.PLUGINS table:

```
SELECT PLUGIN_STATUS, PLUGIN_LIBRARY, PLUGIN_DESCRIPTION, LOAD_OPTION
FROM information_schema.PLUGINS
WHERE PLUGIN_NAME='SERVER_AUDIT'\G
```

```
*************************** 1. row ***************************
     PLUGIN_STATUS: ACTIVE
    PLUGIN_LIBRARY: server_audit2.so
PLUGIN_DESCRIPTION: MariaDB Enterprise Audit
       LOAD_OPTION: FORCE_PLUS_PERMANENT
```

If your output does not match the example output shown above, confirm that the `mariadb-enterprise.cnf` configuration file sets the server-audit option to `FORCE_PLUS_PERMANENT`.

Server Startup Behavior

Some specific server startup behavior is described in the sections below.

For examples of error messages that can appear in the MariaDB error log during server startup, see Messages in MariaDB Error Log.

Enterprise Audit Not Loaded

MariaDB Enterprise Server can startup and handle traffic even if MariaDB Enterprise Audit is not installed or loaded. However, the specific behavior can be configured.

When the server-audit option is set to `FORCE` or `FORCE_PLUS_PERMANENT`, MariaDB Enterprise Server will fail to start if MariaDB Enterprise Audit can't be loaded.

The mariadb-enterprise.cnf configuration file included by default in MariaDB Enterprise Server sets the server-audit option to `FORCE_PLUS_PERMANENT`. As a consequence, MariaDB Enterprise Server forbids MariaDB Enterprise Audit from being uninstalled by default.

Invalid Filter Definitions

MariaDB Enterprise Audit attempts to load the Audit Filters during startup.

When MariaDB Enterprise Audit encounters errors in the Audit Filter definitions, MariaDB Enterprise Server will still start and load MariaDB Enterprise Audit. In this situation, an error will be written to the MariaDB error log and all Events for all objects will be audit logged.

Additional Points of Control

When enabled, MariaDB Enterprise Audit logs designated Events that occur on a running instance of MariaDB Enterprise Server.

Additional audit practices should be established to cover:

- Data backup controls.
- System-level controls, including authentication, file system, and process execution.
- Network-level controls.
- Monitoring systems, including monitoring for audit logging.
- Changes to user accounts (and the mysql.global_priv system table), which can necessitate changes to Audit Filters.

Audit Filters

Filters are JSON objects that specify what you want MariaDB Enterprise Audit to monitor.

There are two types of filters:

Audit Filter Type	Description
Default Audit Filter	The Default Audit Filter is used for all user accounts that are not assigned a Named Audit Filter. Only a single Default Audit Filter can be defined in the `mysql.server_audit_filters` system table, and it must be defined with the name default.
Named Audit Filters	Named Audit Filters must be assigned to specific user accounts. Many Named Audit Filters can be defined in the `mysql.server_audit_filters` system table, and they must be defined with unique names. A Named Audit Filter can be assigned to a user account by inserting the user account details and the filter name into the `mysql.server_audit_users` system table.

Default Audit Filter

The Default Audit Filter applies to all user accounts that do not have a specific Named Audit Filter assigned. Only one Default Audit Filter is allowed in the `mysql.server_audit_filters` system table, and it must be named

`default`.

Create a Default Audit Filter

If you want to create a Default Audit Filter, you need to insert the details into the `mysql.server_audit_filters` system table. The name for the Default Audit Filter must be default and the rule should be designed to meet your audit logging requirements.

To create a Default Audit Filter:

1. Confirm that a Default Audit Filter does not already exist:

```
SELECT * FROM mysql.server_audit_filters
    WHERE filtername = 'default';
```

2. If a Default Audit Filter already exists, remove it:

```
DELETE FROM mysql.server_audit_filters
    WHERE filtername = 'default';
```

3. Insert the details for the new Default Audit Filter into the mysql.server_audit_filters system table:

```
INSERT INTO mysql.server_audit_filters (filtername, rule)
   VALUES ('default',
      JSON_COMPACT(
         '{
            "connect_event":"ALL",
            "table_event":"WRITE"
         }'
      ));
```

This example Audit Filter configures audit logging for all Connection Events and Write Table Events.

The example passes the JSON object to the JSON_COMPACT() function, so that the JSON object is compacted prior to being inserted into the system table. This step is recommended, but not required.

4. Reload the Audit Filters by setting the server_audit_reload_filters system variable to `ON`:

```
SET GLOBAL server_audit_reload_filters=ON;
```

Disable Logging with the Default Filter

It is recommended to use the default filter to assure that any user is audited, also if not defined in the `mysql.server_audit_users` system table.

In some special cases you might want audits only to be enabled for the users in `mysql.server_audit_users`. In this case you should use the following default filter to disable logging for all other users.

```
INSERT INTO mysql.server_audit_filters (filtername, rule)
   VALUES ('default',
      JSON_COMPACT(
         '{
    “logging”: “OFF”
          }'
      ));
```

Named Audit Filters

Named Audit Filters must be assigned to specific user accounts.

Multiple Named Audit Filters can be defined in the mysql.server_audit_filters system table, and they must be defined with unique names. A Named Audit Filter can be assigned to a user account by inserting the user account details and the filter name into the mysql.server_audit_users system table.

Create a Named Audit Filter

To create a Named Audit Filter, insert a row with the Audit Filter's name and the rule into the `mysql.server_audit_filters` system table:

```
INSERT INTO mysql.server_audit_filters (filtername, rule)
   VALUES ('reporting',
      JSON_COMPACT(
         '{
            "connect_event": [
               "CONNECT",
               "DISCONNECT"
            ],
            "table_event":[
               "WRITE",
               "CREATE",
               "DROP",
               "RENAME",
               "ALTER"
            ]
         }'
      ));
```

This example Audit Filter is defined with the name reporting, and it configures audit logging for Connection Events and Disconnection Events and for several types of Table Events. This example Audit Filter can be useful for read-only users since it does not log table reads, but it does log table writes and schema changes which are illegitimate activities for a read-only user.

The example passes the JSON object to the `JSON_COMPACT()` function, so that the JSON object is compacted prior to being inserted into the system table. This step is recommended, but not required.

For additional information on how to assign the Audit Filter to a user account, see "Assign a Named Audit Filter".

Assign a Named Audit Filter

Named Audit Filters are only active when they are assigned to a specific user account.

To assign a Named Audit Filter to a user account:

1. Insert a row with the user account details and the Audit Filter's name into the `mysql.server_audit_users` system table:

```
INSERT INTO mysql.server_audit_users (host, user, filtername)
   VALUES ("%", "reader", "reporting");
```

This example statement assigns the reporting Audit Filter created in "Create a Named Audit Filter" to the `reader@%` user account.

2. Reload the Audit Filters by setting the server_audit_reload_filters system variable to `ON`:

```
SET GLOBAL server_audit_reload_filters=ON;
```

MariaDB Enterprise Audit does not track changes to user accounts. If you delete or rename a user account, the change doesn't cascade to the Audit Filter. The Audit Filters must be updated manually.

System Tables for Audit Filters

There are two system tables for Audit Filters:

System Table	Description
mysql.server_audit_filters	Audit Filter definitions with MariaDB Enterprise Audit
mysql.server_audit_users	Audit Filter assignments for user accounts with MariaDB Enterprise Audit.

Query Audit Filters

You can query Audit Filters by querying the `mysql.server_audit_filters` system table.

The JSON objects can be made more human-readable by passing them to the JSON_DETAILED() or JSON_LOOSE() functions:

```
SELECT filtername,
   JSON_DETAILED(rule)
FROM mysql.server_audit_filters\G
```

```
*************************** 1. row ***************************
         filtername: reporting
JSON_DETAILED(rule): {
    "table_event":
    [
        "WRITE",
        "CREATE",
        "DROP",
        "RENAME",
        "ALTER",

        {
            "log_databases":
            [
                "production",
                "reporting"
            ]
        }
    ]
}
```

Query User Assignments for Named Audit Filters

You can query user assignments for Named Audit Filters by joining the `mysql.server_audit_filters` and `mysql.server_audit_users` system tables.

The JSON objects can be made more human-readable by passing them to the JSON_DETAILED() or JSON_LOOSE() functions:

```
SELECT sau.host, sau.user, saf.filtername,
   JSON_DETAILED(saf.rule)
FROM mysql.server_audit_filters saf
JOIN mysql.server_audit_users sau
   ON saf.filtername = sau.filtername
WHERE saf.filtername != 'default'\G
```

```
*************************** 1. row ***************************
                   host: %
                   user: reader
             filtername: reporting
JSON_DETAILED(saf.rule): {
    "table_event":
    [
        "WRITE",
        "CREATE",
        "DROP",
        "RENAME",
        "ALTER",

        {
            "log_databases":
            [
                "production",
                "reporting"
            ]
        }
    ]
}
*************************** 2. row ***************************
                   host: %
                   user: writer
             filtername: reporting
JSON_DETAILED(saf.rule): {
    "table_event":
    [
        "WRITE",
        "CREATE",
        "DROP",
        "RENAME",
        "ALTER",

        {
            "log_databases":
            [
                "production",
                "reporting"
            ]
        }
    ]
}
```

Reload Audit Filters and Assignments

MariaDB Enterprise Audit caches its Audit Filters to improve performance. When you change an Audit Filter or an Audit Filter assignment in the system tables, you need to reload the Audit Filters for the changes to take effect.

To reload Audit Filters, set the server_audit_reload_filters system variable to ON with the SET GLOBAL statement, which requires the SUPER privilege:

```
SET GLOBAL server_audit_reload_filters=ON;
```

When you set the server_audit_reload_filters system variable to ON, MariaDB Enterprise Audit reloads all Audit Filters and assignments to ensure that it is using the latest definitions. Afterward, it sets `server_audit_reload_filters` back to `OFF`.

For additional information on how to use the server_audit_reload_filters system variable, see “Default Audit Filter” and “Named Audit Filters”.

Event Filters

MariaDB Enterprise Audit supports Event Filters in Audit Filters. Event Filters can be used to configure which Events you want to audit. Each Event refers to a different class of operation.

MariaDB Enterprise Audit defines multiple Event classes that can be used in Event Filters:

- Audit Config Events
- Connect Events
- Query Events
- Table Events

The Event classes are described in the sections below. Example audit logs for each Event class are shown in the sections below. For details about the audit log format, see Audit Log Format.

Audit Config Events

MariaDB Enterprise Audit implements Audit Config Events to help keep track of changes to the audit log configuration.

MariaDB Enterprise Audit logs Audit Config (`AUDIT_CONFIG`) Events in the following situations:

- When one of MariaDB Enterprise Audit's system variables is changed with the SET GLOBAL statement, the change is logged.
- When the audit log file is rotated, it is logged.

In the following output, three audit configuration events (`AUDIT_CONFIG`) and one query event (`QUERY`) are shown:

```
20190622 02:10:21,localhost.localdomain,,,0,0,AUDIT_CONFIG,,file_path=server_audit.log,0
20190622 02:10:21,localhost.localdomain,,,0,0,AUDIT_CONFIG,,rotate_size=1000000,0
20190622 02:10:21,localhost.localdomain,,,0,0,AUDIT_CONFIG,,file_rotations=9,0
20190622 02:10:21,localhost.localdomain,root,localhost,8,7,QUERY,mysql,'set global server_audit_logging =
on',0
```

> **Tip:**
>
> `AUDIT_CONFIG` events are always logged, so no configuration is required when audit logging is started.

Connection Events

MariaDB Enterprise Audit implements Connection Events to audit connection attempts, authentication failures, and user account changes that occur due to certain authentication plugins, such as pam.

MariaDB Enterprise Audit logs Connection Events in the following situations:

- When a user successfully connects, it is logged with the `CONNECT` Event sub-class.
- When a user disconnects, it is logged with the `DISCONNECT` Event sub-class.
- When a user fails to connect, it is logged with the `FAILED_CONNECT` Event sub-class.
- When an existing connection authenticates as a different user, it is logged with the `CHANGE_USER` Event sub-class.
- When an authentication plugin changes to a proxy user, it is logged with the `PROXY_CONNECT` Event sub-class.

In the following output, multiple sub-classes of connection events (`CONNECT` , `DISCONNECT` , `FAILED_CONNECT`) are shown:

```
20190710 00:05:30,localhost.localdomain,root, localhost,2,0,CONNECT,,,0
20190710 00:05:53,localhost.localdomain,root, localhost,2,0,DISCONNECT,,,0
20190710 00:06:28,localhost.localdomain,unknownuser,localhost,3,0,FAILED_CONNECT,,,1045
20190710 00:06:28,localhost.localdomain,unknownuser, localhost,3,0,DISCONNECT,,,0
```

Starting with MariaDB Enterprise Server 12.3, connection events record the client port alongside the host and append the negotiated TLS version:

```
20260731 09:14:22,mdbe123,root,192.168.1.24:54312,7,0,CONNECT,mysql,,0,TLSv1.3
20260731 09:14:59,mdbe123,root,192.168.1.24:54312,7,0,DISCONNECT,mysql,,0,TLSv1.3
20260731 09:15:03,mdbe123,app,localhost:unavailable,8,0,CONNECT,,,0,
```

The third record is an unencrypted Unix socket connection, so it has no client port and no TLS version.

> **Note:**
>
> `PROXY_CONNECT` records do not include the TLS version.

An **event filter for connection events** can be added to an Audit filter with the `connect_event` key, which supports the following values:

Value	Description
CONNECT	Records when the user connects to MariaDB Enterprise Server
DISCONNECT	Records when the user disconnects from MariaDB Enterprise Server
FAILED_CONNECT	Records when a user attempts to connect to MariaDB Enterprise Server, but the connection attempt fails due to authentication or similar issues
CHANGE_USER	Records when a user switches to a different user account
PROXY_CONNECT	Records proxy user connections.
ALL	Records all connection Events

This query defines a Named Audit Filter that specifies connection events:

```
INSERT INTO mysql.server_audit_filters (filtername, rule)
   VALUES ('connections',
      JSON_COMPACT(
         '{
            "connect_event": [
               "CONNECT",
               "DISCONNECT"
            ]
         }'
      ));
```

The example passes the JSON object to the JSON_COMPACT() function, so that the JSON object is compacted prior to being inserted into the system table. This step is recommended, but not required.

Query Events

MariaDB Enterprise Audit implements Query Events to audit the execution of a specific subset of SQL statements.

MariaDB Enterprise Audit logs Query Events in the following situations:

- When a SQL statement is directly executed, it is logged with the `QUERY` event.

MariaDB Enterprise Audit does not log query events for SQL statements that are indirectly executed. For example, if an SQL statement is executed as part of a view, stored procedure, stored function, or trigger, the query will not be logged. If you want to audit all table accesses, including indirect table accesses, it is recommended to enable audit logging for Table Events in addition to query events.

This query shows one query event:

```
20190710 02:21:07,localhost.localdomain,John,localhost,3,30,QUERY,db1,'SELECT * FROM services WHERE
typeid IN (SELECT id FROM services_types WHERE name="consulting")',0
```

An **event filter for query events** can be added to an Audit Filter with the `query_event` key, which supports the following values:

Value	Description
DML	Records any SQL statements in the Data Manipulation Language subset, including SELECT, INSERT, UPDATE, and DELETE statements.
DDL	Records any SQL statements in the Data Definition Language subset, including CREATE TABLE and ALTER TABLE, as well as DROP TABLE and TRUNCATE operations.
DCL	Records any SQL statements in the Data Control Language subset, including GRANT and REVOKE.
DML_READ	Records SELECT statements in the Data Manipulation Language subset.
DML_WRITE	Records any SQL statements for writes in the Data Manipulation Language subset, including INSERT, UPDATE, and DELETE statements.
DML_NO_SELECT	Alias for DML_WRITE
ALL	Records any SQL statements run by the user.

For example, the following query defines a Named Audit Filter that specifies Query Events:

```
INSERT INTO mysql.server_audit_filters (filtername, rule)
   VALUES (
       'queries',
       JSON_COMPACT(
          '{
              "query_event": [
                  "DML",
                  "DDL",
          "DCL",
          "DML_NO_SELECT",
          "DML_WRITE",
          "DML_READ",
          "ALL"
              ]
          }'
       )
    );
```

The example passes the JSON object to the JSON_COMPACT() function, so that the JSON object is compacted prior to being inserted into the system table. This step is recommended, but not required.

> **CURRENT**
>
> MariaDB Enterprise Audit supports Object Filters for Query Events.
>
> **< 10.6 / 10.5.12 / 10.4.21**
>
> MariaDB Enterprise Audit does **not** support Object Filters for Query Events.

Table Events

MariaDB Enterprise Audit implements Table Events to audit when a table is accessed or modified.

MariaDB Enterprise Audit logs Table Events in the following situations:

- When an operation reads from a table, it is logged with the `READ` Event sub-class.
- When an operation writes to a table, it is logged with the `WRITE` Event sub-class.

- When an operation creates a table, it is logged with the `CREATE` Event sub-class.
- When an operation drops a table, it is logged with the `DROP` Event sub-class.
- When an operation alters a table, it is logged with the `ALTER` Event sub-class.
- When an operation renames a table, it is logged with the `RENAME` Event sub-class.

Table Events are logged when a table is accessed or modified directly or indirectly by a query. They complement Query Events very well, because the Query Event causes the raw query to be audit logged, and the Table Event causes all table operations to be audit logged. Both Query Events and Table Events are logged with the query ID, so each Table Event can easily be mapped to its corresponding Query Event. The combination of Query Events and Table Events can be useful when table operations can be hidden by views or triggers.

In the following example output, 6 sub-classes of Table Events are shown:

```
20190710 02:21:06,localhost.localdomain,John,localhost,3,25,CREATE,db1,services,
20190710 02:21:06,localhost.localdomain,John,localhost,3,27,READ,db1,services,
20190710 02:21:07,localhost.localdomain,John,localhost,3,29,WRITE,db1,services,
20190710 02:21:27,localhost.localdomain,John,localhost,3,35,ALTER,db1,services,
20190710 02:21:27,localhost.localdomain,John,localhost,3,36,RENAME,db1,services,db1,services_new
20190710 02:21:45,localhost.localdomain,John,localhost,3,38,DROP,db1,services_new,
```

When a query uses the `DELAYED` keyword, it is executed by a system user. In this case, any Table Event associated with the query is written to the audit log with the user set to `DELAYED`. However, the Query Event associated with the query is written to the audit log with the original user:

```
20190622 02:10:21,localhost.localdomain,root,localhost,8,5,QUERY,test,'INSERT DELAYED INTO t1 VALUES(1),
(2),(3);',0
20190622 02:10:25,localhost.localdomain,root,localhost,2,2,WRITE,test,t1,
20190622 02:10:25,localhost,DELAYED,localhost,2,2,WRITE,test,t1,
```

When your application executes queries with the `DELAYED` keyword, it is recommended to enable audit logging for Query Events in addition to Table Events to ensure that the full details are logged.

If the query cache is enabled, `READ` Table Events may not be audit logged. If MariaDB Enterprise Audit detects that the query cache is enabled during startup, MariaDB Enterprise Audit writes the following message to the MariaDB error log:

```
2021-07-23  0:11:26 server_audit: Query cache is enabled with the TABLE events. Some table reads can be
veiled.
```

An Event Filter for Table Events can be added to an Audit Filter with the `table_event` key, which supports the following values:

Value	Description
READ	Records read operations run on table objects, such as from a `SELECT` statement or an `INSERT SELECT`
WRITE	Records write operations run on table objects, such as `INSERT` or `UPDATE` statements
CREATE	Records any creation operations run on table objects, such as from a `CREATE TABLE` or `CREATE SERVER`.
DROP	Records any deletion operations run on table objects, such as `DELETE` or `DROP TABLE`.
ALTER	Records any modifications made on table objects, such as `ALTER TABLE` or `ALTER USER`.
RENAME	Records any renaming operations run on table objects, such as `RENAME TABLE`
ALL	Records all operations run on table objects

For example, the following query defines a Named Audit Filter that specifies Table Events:

```
INSERT INTO mysql.server_audit_filters (filtername, rule)
   VALUES (
       'tables',
       JSON_COMPACT(
           '{
              "table_event": [
                  "WRITE",
                  "CREATE",
                  "DROP",
                  "RENAME",
                  "ALTER"
              ]
           }'
       )
    );
```

The example passes the JSON object to the JSON_COMPACT() function, so that the JSON object is compacted prior to being inserted into the system table. This step is recommended, but not required.

> **CURRENT**
>
> MariaDB Enterprise Audit supports Object Filters for Table Events.
>
> **< 10.6 / 10.5.12 / 10.4.21**
>
> MariaDB Enterprise Audit does **not** support Object Filters for Table Events.

Logging Filter

MariaDB Enterprise Audit supports a special Logging Filter that can be used in Audit Filters to enable or disable audit logging for any users that are assigned the Audit Filter.

The Logging Filter can be added to an Audit Filter with the logging key, which supports the following values:

Value	Description
ON	Enables audit logging for this Audit Filter
OFF	Disables audit logging for this Audit Filter

For example, the following query defines a Default Audit Filter that enables logging for all Events for any user account without a Named Audit Filter:

```
INSERT INTO mysql.server_audit_filters (filtername, rule)
   VALUES (
       'default',
       JSON_COMPACT(
           '{
              "logging": "ON"
           }'
       )
    );
```

The example passes the JSON object to the JSON_COMPACT() function, so that the JSON object is compacted prior to being inserted into the system table. This step is recommended, but not required.

Object Filters

> **Note:**
>
> Object Filters are available from MariaDB 10.6, 10.5.12, and 10.4.21.

Object Filters allow Audit Filters to be limited to specific databases and/or tables. Object Filters can be specified at different scopes:

- An Object Filter can be specified for an entire Audit Filter
- An Object Filter can be specified for a single Event for the Audit Filter

Object Filter Format

Object Filters are formatted as JSON objects, which are key-value pairs.

For Object Filters, the key in the key-value pair refers to the specific type of Object Filter. The following types of Object Filters are supported:

Audit Log?	Object Filter Key	Description
No	ignore_databases	When one or more databases are specified with the `ignore_databases` Object Filter key, the specified databases are not audit-logged. The `ignore_databases` Object Filter key is an alias for the `ignore_tables` Object Filter key, with the table identifier set to the wildcard character (`*`). The ignore_databases Object Filter key cannot be specified in the same Object Filter as the `log_databases` and `log_tables` Object Filter keys.
No	ignore_tables	When one or more tables are specified with the `ignore_tables` Object Filter key, the specified tables will not be audit logged. Table names must be provided in the form *`database.table`*. Wildcard characters (`*`) are allowed. The `ignore_tables` Object Filter key cannot be specified in the same Object Filter as the `log_databases` and `log_tables` Object Filter keys.
Yes	log_databases	When one or more databases are specified with the `log_databases` Object Filter key, the specified databases will be audit logged, and all other databases will not be audit logged. The `log_databases` Object Filter key is an alias for the `log_tables` Object Filter key, with the table identifier set to the wildcard character (`*`).
Yes	log_tables	When one or more databases are specified with the `log_tables` Object Filter key, the specified tables will be audit logged, and all other tables will not be audit logged. Table names must be provided in the form *`database.table`*. Wildcard characters (`*`) are allowed.

The values in the key-value pair refer to object names.

When the Object Filter only applies to one object, the object name can be specified as a string scalar value in the JSON object:

```
{"object_filter_key": "object"}
```

When the Object Filter applies to multiple objects, the object names can be specified in a JSON array in the JSON object:

```
{"object_filter_key": [ "object", "object" ]}
```

In the following example, the Object Filter is designed to audit log the production and reporting databases and to skip audit logging for all other databases and tables:

```
{"log_tables": ["production.*", "reporting.*"]}
```

And in the following example, the Object Filter is designed to skip audit logging for the production.app_log table:

```
{"ignore_tables": "production.app_log"}
```

The Object Filter keys must be specified in different locations in the Audit Filter's JSON object, depending on the desired scope of the Object Filter. The following sections describe how to set Object Filters in more detail.

Set Object Filters at Event Scope

An Object Filter can be specified for a single Event Filter within an Audit Filter.

Object Filters are supported by the following Events:

- Query Events
- Table Events

To create an Object Filter for a single Event Filter, specify the Object Filter's JSON object as part of the JSON object for the Event Filter.

The examples below pass the JSON object to the JSON_COMPACT() function, so that the JSON object is compacted prior to being inserted into the system table. This step is recommended, but not required.

In the following example, the reporting Audit Filter specifies an Event Filter for Table Events with an embedded Object Filter that includes all tables in the production and reporting databases:

```
INSERT INTO mysql.server_audit_filters (filtername, rule)
   VALUES (
       'reporting',
       JSON_COMPACT(
           '{
              "table_event": [
                  "WRITE",
                  "CREATE",
                  "DROP",
                  "RENAME",
                  "ALTER",
                  {
                     "log_tables": [
                        "production.*",
                        "reporting.*"
                     ]
                  }
              ]
           }'
       )
    );
```

Set Object Filters at Audit Filter Scope

An Object Filter can be specified for an entire Audit Filter.

To create an Object Filter at Audit Filter scope, specify the Object Filter's JSON object as part of the root JSON object for the Audit Filter.

The examples below pass the JSON object to the JSON_COMPACT() function, so that the JSON object is compacted prior to being inserted into the system table. This step is recommended, but not required.

In the following example, the reporting Audit Filter specifies an Object Filter that includes all tables in the production and reporting databases:

```
INSERT INTO mysql.server_audit_filters (filtername, rule)
   VALUES (
       'reporting',
       JSON_COMPACT(
          '{
              "log_tables": [
                  "production.*",
                  "reporting.*"
              ]
          }'
       )
    );
```

When an Object Filter is specified at Audit Filter scope, it can contain embedded Event Filters. The following Event types support Object Filters:

- Query Events
- Table Events

In the following example, the reporting Audit Filter has been modified to include Event Filters on specific Query Event sub-classes and Table Event sub-classes:

```
INSERT INTO mysql.server_audit_filters (filtername, rule)
   VALUES (
       'reporting',
       JSON_COMPACT(
          '{
              "log_tables": [
                  "production.*",
                  "reporting.*",
                  {
                     "query_event": [
                         "DML",
                         "DDL"
                     ],
                     "table_event": [
                         "WRITE",
                         "CREATE",
                         "DROP",
                         "RENAME",
                         "ALTER"
                     ]
                  }
              ]
          }'
       )
    );
```

Combine Object Filters at Audit Filter and Event Scope

When an Object Filter is specified at Audit Filter scope with embedded Event Filters, the embedded Event Filters can contain additional Object Filters. When you combine Object Filters at different levels, it is possible to combine Object Filters that are normally incompatible, like tables and ignore_tables.

To create Object Filters at Audit Filter and Event Type scope, specify the JSON object for the Object Filter at Audit Filter scope as part of the root JSON object for the Audit Filter and specify the JSON object for the Object Filter at Event Type scope as part of the JSON object for the Event Filter.

The examples below pass the JSON object to the JSON_COMPACT() function, so that the JSON object is compacted prior to being inserted into the system table. This step is recommended, but not required.

In the following example, the reporting Audit Filter specifies an Event Filter for Table Events with an embedded Object Filter that includes all tables in the production and reporting databases, but it excludes Query Events that

target specific tables that store Personally Identifiable Information (PII), so that the sensitive information does not appear in the audit log:

```
INSERT INTO mysql.server_audit_filters (filtername, rule)
   VALUES (
       'reporting',
       JSON_COMPACT(
          '{
              "log_tables": [
                  "production.*",
                  "reporting.*",
                  {
                     "table_event": [
                         "WRITE",
                         "CREATE",
                         "DROP",
                         "RENAME",
                         "ALTER"
                     ],
                     "query_event": [
                         "DML",
                         "DDL",
                         {
                             "ignore_tables": [
                                 "production.customer_profiles",
                                 "production.customer_addresses"
                             ]
                         }
                     ]
                  }
              ]
          }'
       )
    );
```

Audit Log Destinations

MariaDB Enterprise Audit writes audit log messages either to a dedicated audit log file or to the system log (syslog), depending on configuration.

The audit log destination is configured with the dit_output_type|server_audit_output_type system variable:

Value	Description
FILE	Audit log messages are written to a dedicated file.
SYSLOG	Audit log messages are written to the system log (syslog).

Audit Logging to File

MariaDB Enterprise Audit writes audit log messages to a dedicated audit log file when the dit_output_type|server_audit_output_type system variable is set to FILE.

Audit Log Path

The path to the dedicated audit log file is configured with the server_audit_file_path system variable. The path can be a relative or absolute path. If it is a relative path, then it will be relative to the datadir. For example, to set the path to mariadb-enterprise-audit.log with the SET GLOBAL statement:

```
SET GLOBAL server_audit_file_path = 'mariadb-enterprise-audit.log'
```

When a system variable is dynamically changed with the SET GLOBAL statement, the change does not survive server restarts. To ensure that the new path is used when the server restarts, set the server_audit_file_path system

variable in a configuration file:

```
[mariadb]
server_audit_file_path=mariadb-enterprise-audit.log
```

Audit Log Rotation

When MariaDB Enterprise Audit is configured to use the dedicated audit log file, it can rotate the file.

The file is rotated when its size exceeds the size specified by the server_audit_file_rotate_size system variable. For example, to set the maximum log size to 2 GB with the SET GLOBAL statement:

```
SET GLOBAL server_audit_file_rotate_size = 2 * (1024 * 1024 * 1024);
```

When a system variable is dynamically changed with the SET GLOBAL statement, the change does not survive server restarts. To ensure that the new file rotation size is used when the server restarts, set the server_audit_file_rotate_size system variable in a configuration file:

```
[mariadb]
server_audit_file_rotate_size=2147483648
```

The file can also be rotated manually by setting the server_audit_file_rotate_now system variable to `ON`. For example, to rotate the log with the SET GLOBAL statement:

```
SET GLOBAL server_audit_file_rotate_now = ON;
```

Audit Logging to System Log

MariaDB Enterprise Audit writes audit log messages to the system log (syslog) when the server_audit_output_type system variable is set to SYSLOG.

It can be very useful to configure audit logging to the syslog when your system's syslog is configured to securely transmit logs to a remote syslog server.

System Log Parameters

Several syslog parameters can be changed for MariaDB Enterprise Audit by setting the following system variables:

- server_audit_syslog_facility
- server_audit_syslog_ident
- server_audit_syslog_info
- server_audit_syslog_priority

Audit Log Format

The audit log format for MariaDB Enterprise Audit depends on the audit log destination.

Formal Specification

When MariaDB Enterprise Audit is configured to use a dedicated file, it records events in a comma-separated (CSV) format. For tool developers, it is critical to use standardized field mappings to correlate audit data with other server logs.

Template: `<timestamp>,<serverhost>,<username>,<host>:<port>,<connectionid>,<queryid>,<operation>,<database>,<object>,<retcode>,<tlsversion>`

Field	Component	Data Type	Standardized Name / Description
1	`timestamp`	`DateTime`	Formatted as `%Y%m%d %H:%i:%s` (the default), or as described below.
2	`serverhost`	`String`	The hostname of the server instance.
3	`username`	`String`	The MariaDB user account triggering the event.
4	`host:port`	`String`	The client host from which the user connected, followed by a colon and the client's TCP port. The port is written as `unavailable` when the client did not connect over TCP/IP, such as over a Unix socket or a named pipe. The port was added in MariaDB Enterprise Server 12.3.
5	`connectionid`	`Unsigned Int`	Standardized: Thread ID. Matches the `Thread ID` in Error, General, and Slow logs.
6	`queryid`	`Unsigned Int`	A unique identifier for the specific query. Used to link Query and Table events.
7	`operation`	`String`	The type of action (e.g., `CONNECT`, `QUERY`, `WRITE`).
8	`database`	`String`	The name of the database being accessed.
9	`object`	`String`	The specific table or object involved in the operation.
10	`retcode`	`Integer`	The return code; `0` indicates success, non-zero indicates an error code.
11	`tlsversion`	`String`	The TLS version negotiated for the connection, such as `TLSv1.3`. Present only on connection events, and empty when the connection is not encrypted. Added in MariaDB Enterprise Server 12.3.

Warning:

Changed in MariaDB Enterprise Server 12.3

Two changes to the log format require updates to tools that parse the audit log:

- The `host` field now contains a colon and the client port.
- Connection event records carry an eleventh field. Records for all other operations still end at `retcode`.

Milliseconds Precision Timestamps

Auditing regulations and standards require auditing logs with timestamps recording fractions of a second and timezone information. To fulfill this requirement, MariaDB Enterprise Audit uses the system log (syslog) via the server_audit_output_type option, where the timestamp format is controlled by the syslog setting.

To define the format of the timestamp:

- Configure `server_audit_output_type=file`.
- Change the default setting of `%Y%m%d %H:%i:%s` (which assures compatibility) to something including milliseconds (`%f`) and time zone information (`%z`), like `%Y%m%dT%H:%i:%s.%f%z`.

This results in audit log entries like these:

```
# for server_audit_timestamp_format=%Y%m%dT%H:%i:%s.%f%z
20231207T13:14:28.000000+0100,mdbe106,root,localhost,4,0,CONNECT,,,0
20231207T13:14:32.481161+0100,mdbe106,root,localhost,4,0,DISCONNECT,,,0
```

Value Mapping for Operations

To build accurate filters and parsers, the `<operation>` field corresponds to the following standardized event types:

Operation	Triggered By
`CONNECT`	Successful user authentication and connection.
`FAILED_CONNECT`	Authentication failures or denied access.
`DISCONNECT`	Session termination.
`QUERY`	Direct execution of a SQL statement.
`READ`	Table read access (e.g., `SELECT`).
`WRITE`	Table modification (e.g., `INSERT`, `UPDATE`, `DELETE`).
`AUDIT_CONFIG`	Changes to audit settings via `SET GLOBAL` or log rotation.

Audit Log Format with Syslog

When configured to use `SYSLOG`, the standard CSV line is prefixed with syslog metadata: `<timestamp> <syslog_host> <syslog_ident>: <syslog_info> [Standard CSV Fields]`

Messages in MariaDB Error Log

MariaDB Enterprise Audit writes messages to the MariaDB Error Log in various scenarios. Some of the scenarios and log messages are described below.

Load Plugin

When MariaDB Enterprise Server loads the plugin for MariaDB Enterprise Audit, MariaDB Enterprise Audit writes the following message in the MariaDB error log:

```
2021-08-03 21:07:03 server_audit: MariaDB Audit Plugin version 2.0.3 STARTED.
```

For additional information, see “Load the Audit Plugin”.

Unload Plugin

When MariaDB Enterprise Server unloads the plugin for MariaDB Enterprise Audit, MariaDB Enterprise Audit writes the following message in the MariaDB error log:

```
2021-08-02 23:54:59 server_audit: STOPPED
```

The plugin is unloaded when MariaDB Enterprise Server is shutdown, so this message is most commonly written to the MariaDB error log during the shutdown process.

Start Audit Logging to File

When audit logging is started and it is directed to a file, MariaDB Enterprise Audit writes the following message in the MariaDB error log:

```
2021-08-03 21:39:42 server_audit: logging started to the file server_audit.log.
```

If a custom audit log path is configured, then the message will refer to the custom path.

For additional information, see “Start Audit Logging” and “Audit Logging to File”.

Start Audit Logging to Syslog

When audit logging is started and it is directed to syslog, MariaDB Enterprise Audit writes the following message in the MariaDB error log:

For additional information, see “Start Audit Logging” and “Audit Logging to Syslog”.

```
2021-08-03 22:02:45 server_audit: logging started to the syslog.
```

Stop Audit Logging

When audit logging is stopped, MariaDB Enterprise Audit writes the following message in the MariaDB error log:

```
2021-08-03 21:39:50 server_audit: logging was stopped.
```

Change Audit Logging to File

When audit logging is changed to a file, MariaDB Enterprise Audit writes the following message in the MariaDB error log:

```
2021-08-03 22:03:31 server_audit: Output was redirected to 'file'
```

For additional information, see “Audit Logging to File”.

Change Audit Logging to Syslog

When audit logging is changed to syslog, MariaDB Enterprise Audit writes the following message in the MariaDB error log:

```
2021-08-03 22:01:22 server_audit: Output was redirected to 'syslog'
```

For additional information, see “|mariadb-enterprise-audit/#audit-logging-to-system-logAudit Logging to Syslog”.

Change File Name for Audit Logging

When the file name for audit logging is changed, MariaDB Enterprise Audit writes the following message in the MariaDB error log:

```
2021-08-03 22:05:17 server_audit: Log file name was changed to 'mariadb-enterprise-audit.log'.
```

For additional information, see “Audit Log Path”.

Reload Invalid Audit Filters

When the Audit Filters are reloaded and one or more of the Audit Filters are invalid, MariaDB Enterprise Audit writes the following message in the MariaDB error log:

```
2021-08-03 21:51:55 server_audit: Unknown filter function tables.
2021-08-03 21:51:55 server_audit: Can't parse filter's 'production' definition { "tables": "production.*"
}.
2021-08-03 21:51:55 server_audit: can't load filters - old filters are saved.
```

For additional information, see “Reload Audit Filters and Assignments”.

Conflict with the Query Cache

If the query cache is enabled, `READ` Table Events may not be audit logged. If MariaDB Enterprise Audit detects during startup that the query cache is enabled, MariaDB Enterprise Audit writes the following message to the MariaDB error log:

```
2021-08-03 21:07:03 server_audit: Query cache is enabled with the TABLE events. Some table reads can be
veiled.
```

Upgrades

MariaDB Enterprise Audit is included with MariaDB Enterprise Server. Special consideration is needed when upgrading from MariaDB releases that include the MariaDB Audit Plugin, including MariaDB Community.

For details on how to upgrade from the MariaDB Audit Plugin to MariaDB Enterprise Audit, see the sections below.

Warning:

Before upgrading the package: Remove the v1 plugin **and** every `server_audit_*` variable setting from your configuration files *before* running `apt upgrade` (or your platform's equivalent). The new Enterprise Server does not recognize the v1 variables and will fail to start if they remain. Follow the pre-upgrade cleanup steps below.

Important:

Migrating from MariaDB Audit Plugin (v1)

MariaDB Enterprise Audit (`server_audit2.so`) is a different and incompatible plugin from the older MariaDB Audit Plugin (`v1` , `server_audit.so`) found in Community Server or older Enterprise Server versions.

The `v1` plugin is configured with server variables (e.g., `server_audit_events`).

The Enterprise (`v2`) plugin is configured with system tables (e.g., `mysql.server_audit_filters`).

You must uninstall the `v1` plugin before using the `v2` plugin, as running both can cause server instability or deadlocks (MENT-545). The following sections guide you through the full migration process, starting with checking for and removing the old plugin.

Check for and Uninstall the v1 Plugin

Confirm the MariaDB Audit Plugin is Loaded

To confirm that the MariaDB Audit plugin is loaded, query the information_schema.PLUGINS table:

```
SELECT PLUGIN_STATUS, PLUGIN_LIBRARY, PLUGIN_DESCRIPTION
FROM information_schema.PLUGINS
WHERE PLUGIN_NAME='SERVER_AUDIT'\G
```

```
*************************** 1. row ***************************
     PLUGIN_STATUS: ACTIVE
    PLUGIN_LIBRARY: server_audit.so
PLUGIN_DESCRIPTION: Audit the server activity
```

If you see the output shown above, then the MariaDB Audit plugin is installed, and it must be uninstalled prior to performing the upgrade or migration. Follow the instructions in the section below.

If you do not see any rows in the output, then the MariaDB Audit plugin is not installed.

Determine Uninstallation Method

The MariaDB Audit plugin has multiple uninstallation methods. You must choose the uninstallation method that corresponds to how the plugin was installed on your system.

To determine the uninstallation method, query the mysql.plugin system table:

```
SELECT *
FROM mysql.plugin
WHERE name = 'SERVER_AUDIT'\G
```

```
*************************** 1. row ***************************
name: SERVER_AUDIT
  dl: server_audit.so
```

If you see the output shown above, then the MariaDB Audit plugin can be uninstalled with UNINSTALL SONAME.

If you do not see any rows in the output, then the MariaDB Audit plugin call be uninstalled by editing the configuration file.

Uninstall with UNINSTALL SONAME

To uninstall the MariaDB Audit Plugin with UNINSTALL SONAME:

Step 1

Check the plugin load option by querying the information_schema.PLUGINS table:

```
SELECT PLUGIN_STATUS, PLUGIN_LIBRARY, PLUGIN_DESCRIPTION, LOAD_OPTION
FROM information_schema.PLUGINS
WHERE PLUGIN_NAME='SERVER_AUDIT'\G
```

```
*************************** 1. row ***************************
     PLUGIN_STATUS: ACTIVE
    PLUGIN_LIBRARY: server_audit.so
PLUGIN_DESCRIPTION: Audit the server activity
       LOAD_OPTION: FORCE_PLUS_PERMANENT
```

Step 2

Check `LOAD_OPTION` column for `FORCE_PLUS_PERMANENT`

> **Note:**
>
> If the `LOAD_OPTION` column does not contain the value `FORCE_PLUS_PERMANENT`, then you can skip to step 5, which executes the UNINSTALL SONAME statement.

If the `LOAD_OPTION` column contains the value `FORCE_PLUS_PERMANENT`, then check your configuration files for the server-audit option:

```
$ grep --extended-regexp --with-filename \
   'server[-_]audit[[:blank:]]*=' \
   /etc/mysql/my.cnf \
   /etc/mysql/mariadb.conf.d/*
```

```
/etc/mysql/mariadb.conf.d/enable-audit.cnf:server_audit=FORCE_PLUS_PERMANENT
```

Step 3

If the server-audit option was found in a configuration file, then remove or comment the option out:

```
[mariadb]
# server_audit=FORCE_PLUS_PERMANENT
```

Step 4

If the configuration file was changed, then restart the server:

```
$ sudo systemctl restart mariadb
```

Step 5

Uninstall the plugin by executing the UNINSTALL SONAME statement:

```
UNINSTALL SONAME 'server_audit';
```

Step 6

Confirm the plugin is uninstalled by querying the mysql.plugin system table:

```
SELECT *
FROM mysql.plugin
WHERE name = 'SERVER_AUDIT'\G
```

If the query returns no results, then the plugin has been uninstalled.

Uninstall with Configuration File

To uninstall the MariaDB Audit plugin with a configuration file:

Step 1

Check your configuration files for the `plugin_load_add` option:

```
$ grep --extended-regexp --with-filename \
   'plugin[-_]load[-_]add[[:blank:]]*=[[:blank:]]*server_audit' \
   /etc/mysql/my.cnf \
   /etc/mysql/mariadb.conf.d/*
```

```
/etc/mysql/mariadb.conf.d/enable-audit.cnf:plugin_load_add=server_audit
```

Step 2

Remove or comment out the plugin_load_add option from the configuration file:

```
[mariadb]
# plugin_load_add=server_audit
```

Remove v1 Variable Settings

After uninstalling the plugin, also remove every `server_audit_*` system variable from your configuration files. If any of these settings remain, the new Enterprise Server will fail to start because it does not recognize them.

```
$ grep --extended-regexp --with-filename \
   'server_audit[_a-z]*[[:blank:]]*=' \
   /etc/mysql/my.cnf \
   /etc/mysql/mariadb.conf.d/*
```

Comment out or delete every matching line. Common variables include `server_audit_events`, `server_audit_logging`, `server_audit_incl_users`, `server_audit_excl_users`, `server_audit_file_path`, `server_audit_output_type`, `server_audit_query_log_limit`, and `server_audit_file_rotate_size`.

Migrate v1 Settings to Enterprise Audit (v2)

Update System Tables

After upgrading to MariaDB Enterprise Server, execute `mariadb-upgrade` to create the System Tables for Audit Filters.

> **Note:**
>
> If `mariadb-upgrade` reports that the installation is already up to date — for example, when upgrading from Community Server 10.6 to Enterprise Server 10.6 — the audit-filter system tables will not be created. In that case, run `mariadb-upgrade --force` to force the upgrade scripts to run anyway. See mariadb-upgrade for the full behaviour.

Migrate Audit Filters

The MariaDB Audit Plugin defines Audit Filters using the server_audit_events system system variable, but MariaDB Enterprise Audit defines Audit Filters using the mysql.server_audit_filters system table.

If you are upgrading from the MariaDB Audit Plugin to MariaDB Enterprise Audit, perform the following procedure:

Step 1

Remove or comment out lines involving the server_audit_events system variable from the configuration file:

```
[mariadb]
...
# server_audit_events=CONNECT,QUERY
```

Step 2

Insert a replacement Audit Filter into the `mysql.server_audit_filters` system table:

```
INSERT INTO mysql.server_audit_filters
   VALUES ('default',
      JSON_COMPACT(
         '{
            "connect_event": "ALL",
            "query_event": "ALL"
         }'
      ));
```

The example passes the JSON object to the JSON_COMPACT() function, so that the JSON object is compacted prior to being inserted into the system table. This step is recommended, but not required.

Migrate Users

The MariaDB Audit Plugin enables or disable audit logging for specific user accounts using the server_audit_incl_users and server_audit_excl_users system variables, but MariaDB Enterprise Audit uses the mysql.server_audit_users system table.

If you are upgrading from the MariaDB Audit Plugin to MariaDB Enterprise Audit, perform the following procedure:

Step 1

Edit configuration file

Remove or comment out lines involving the server_audit_incl_users and server_audit_excl_users system variables from the configuration file:

```
[mariadb]
...
# server_audit_incl_users = root,app
# server_audit_excl_users = backup_user,monitor_user
```

Step 2

For the server_audit_incl_users system variable

For any user account previously mentioned in the server_audit_incl_users system variable, determine if the user account can use the Default Audit Filter or if the user account requires a Named Audit Filter.

Insert the relevant Audit Filters into the `mysql.server_audit_filters` system table, and insert the user assignments into the `mysql.server_audit_users` system table:

```
INSERT INTO mysql.server_audit_filters
   VALUES
   ('default',
      JSON_COMPACT(
         '{
            "connect_event": [
               "CONNECT",
               "DISCONNECT"
            ],
            "query_event": [
               "DML",
               "DDL"
            ]
         }'
   )),
   ('root_filter',
      JSON_COMPACT(
         '{
            "logging": "ON"
         }'
   ));
INSERT INTO mysql.server_audit_users (host, user, filtername)
   VALUES ('%', 'root', 'root_filter');
```

The example passes the JSON object to the JSON_COMPACT() function, so that the JSON object is compacted prior to being inserted into the system table. This step is recommended, but not required.

Step 3

For the server_audit_excl_users system variable

For any user account previously mentioned in the server_audit_excl_users system variable, create a Named Audit Filter that acts as an exclusion filter.

Insert the relevant Audit Filters into the `mysql.server_audit_filters` system table, and insert the user assignments into the `mysql.server_audit_users` system table:

```
INSERT INTO mysql.server_audit_filters
   VALUES ('exclusion_filter',
      JSON_COMPACT(
         '{
            "logging": "OFF"
         }'
      ));

INSERT INTO mysql.server_audit_users (host, user, filtername)
   VALUES
   ('%', 'backup_user', 'exclusion_filter'),
   ('%', 'monitor_user', 'exclusion_filter');
```

MariaDB Community Audit Plugin

See Audit Plugin Overview.

The MariaDB Audit Plugin records server activity, including connections, queries, and table access, to help meet organizational auditing and compliance regulations.

See Audit Plugin Installation.

Follow this guide to install the Audit Plugin on your MariaDB server. Learn how to verify the plugin file's location, load it dynamically, or configure it to load automatically at startup.

See Audit Plugin Configuration.

Configure the Audit Plugin to suit your monitoring requirements. Learn how to enable logging, select specific event types to record, and exclude specific users from the audit trail.

See Audit Plugin Log Settings.

Control where and how the audit data is stored. This section explains how to direct output to a file or the system syslog, and how to configure logging parameters for different environments.

See Audit Plugin Location and Rotation of Logs.

Manage your audit log files effectively. Learn how to define the log file path, set size limits, and configure rotation strategies to prevent log files from consuming all available disk space.

See Audit Plugin Log Format.

Understand the structure of audit log entries. This guide breaks down the fields in the log records, including timestamps, server IDs, user details, and the specific operations performed.

See Audit Plugin Options and System Variables.

Browse the complete reference of system variables for the Audit Plugin. Use these settings to fine-tune logging behavior, control performance impact, and manage log file handling.

See Audit Plugin Status Variables.

Monitor the performance and status of the Audit Plugin. View variables that track the number of logged events and current settings to ensure the auditing system is functioning correctly.

See Audit Plugin Versions.

Review the version history of the MariaDB Audit Plugin. Check compatibility with different MariaDB Server releases and identify which features or bug fixes are included in each version.

Audit Plugin Overview

MariaDB and MySQL are used in a broad range of environments, but if you needed to record user access to be in compliance with auditing regulations for your organization, you would previously have had to use other database solutions. To meet this need, though, MariaDB has developed the MariaDB Audit Plugin. Although the MariaDB Audit Plugin has some unique features available only for MariaDB, it can be used also with MySQL.

Basically, the purpose of the MariaDB Audit Plugin is to log the server's activity. For each client session, it records who connected to the server (i.e., user name and host), what queries were executed, and which tables were accessed and server variables that were changed. This information is stored in a rotating log file or it may be sent to the local `syslogd`.

Audit Plugin Installation

The `server_audit` plugin logs the server's activity. For each client session, it records who connected to the server (i.e., user name and host), what queries were executed, and which tables were accessed and server variables that were changed. This information is stored in a rotating log file or it may be sent to the local syslogd.

Locating the Plugin

The `server_audit` plugin's shared library is included in MariaDB packages as the `server_audit.so` or `server_audit.dll` shared library on systems where it can be built.

The plugin must be located in the plugin directory, the directory containing all plugin libraries for MariaDB. The path to this directory is configured by the plugin_dir system variable. To see the value of this variable and thereby

determine the file path of the plugin library, execute the following SQL statement:

```
SHOW GLOBAL VARIABLES LIKE 'plugin_dir';

+---------------+--------------------------+
| Variable_name | Value                    |
+---------------+--------------------------+
| plugin_dir    | /usr/lib64/mysql/plugin/ |
+---------------+--------------------------+
```

Check the directory returned at the filesystem level to make sure that you have a copy of the plugin library, `server_audit.so` or `server_audit.dll`, depending on your system. It's included in recent installations of MariaDB. If you do not have it, you should upgrade MariaDB.

Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN:

```
INSTALL SONAME 'server_audit';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the –plugin-load or the –plugin-load-add options. This can be specified as a command-line argument to `mariadbd`, or it can be specified in a relevant server option group in an option file:

```
[mariadb]
...
plugin_load_add = server_audit
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN:

```
UNINSTALL SONAME 'server_audit';
```

If you installed the plugin by providing the –plugin-load or the –plugin-load-add options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Prohibiting Uninstallation

The UNINSTALL SONAME or UNINSTALL PLUGIN statements may be used to uninstall plugins. For the `server_audit` plugin, you might want to disable this capability. To prevent the plugin from being uninstalled, you could set the server_audit option to `FORCE_PLUS_PERMANENT` in a relevant server option group in an option file after the plugin is loaded once:

```
[mariadb]
...
plugin_load_add = server_audit
server_audit=FORCE_PLUS_PERMANENT
```

Once you've added the option to the server's option file and restarted the server, the plugin can't be uninstalled. If someone tries to uninstall the audit plugin, then an error message will be returned. Below is an example of the error message:

```
UNINSTALL PLUGIN server_audit;

ERROR 1702 (HY000):
Plugin 'server_audit' is force_plus_permanent and can not be unloaded
```

For more information on `FORCE_PLUS_PERMANENT` and other option values for the server_audit option, see Plugin Overview: Configuring Plugin Activation at Server Startup for more information.

Audit Plugin Configuration

After the audit plugin has been installed and loaded, there will be some new global variables within MariaDB. These can be used to configure many components, limits, and methods related to auditing the server. You may set these variables related to the logs, such as their location, size limits, rotation parameters, and method of logging information. You may also set what information is logged, such connects, disconnects, and failed attempts to connect. You can also have the audit plugin log queries, read and write access to tables. So as not to overload your logs, the audit plugin can be configured based on lists of users. You can include or exclude the activities of specific users in the logs.

To see a list of audit plugin-related variables on the server and their values, execute the follow while connected to the server:

CURRENT

```
SHOW GLOBAL VARIABLES LIKE 'server_audit%';
+-------------------------------+-----------------------+
| Variable_name                 | Value                 |
+-------------------------------+-----------------------+
| server_audit_events           |                       |
| server_audit_excl_users       |                       |
| server_audit_file_buffer_size | 0                     |
| server_audit_file_path        | server_audit.log      |
| server_audit_file_rotate_now  | OFF                   |
| server_audit_file_rotate_size | 1000000               |
| server_audit_file_rotations   | 9                     |
| server_audit_incl_users       |                       |
| server_audit_logging          | OFF                   |
| server_audit_mode             | 0                     |
| server_audit_output_type      | file                  |
| server_audit_query_log_limit  | 1024                  |
| server_audit_sync_log_file    | OFF                   |
| server_audit_syslog_facility  | LOG_USER              |
| server_audit_syslog_ident     | mysql-server_auditing |
| server_audit_syslog_info      |                       |
| server_audit_syslog_priority  | LOG_INFO              |
+-------------------------------+-----------------------+
17 rows in set (0.003 sec)
```

< 12.1

```
SHOW GLOBAL VARIABLES LIKE 'server_audit%';

+-------------------------------+-----------------------+
| Variable_name                 | Value                 |
+-------------------------------+-----------------------+
| server_audit_events           | CONNECT,QUERY,TABLE   |
| server_audit_excl_users       |                       |
| server_audit_file_path        | server_audit.log      |
| server_audit_file_rotate_now  | OFF                   |
| server_audit_file_rotate_size | 1000000               |
| server_audit_file_rotations   | 9                     |
| server_audit_incl_users       |                       |
| server_audit_logging          | ON                    |
| server_audit_mode             | 0                     |
| server_audit_output_type      | file                  |
| server_audit_query_log_limit  | 1024                  |
| server_audit_syslog_facility  | LOG_USER              |
| server_audit_syslog_ident     | mysql-server_auditing |
| server_audit_syslog_info      |                       |
| server_audit_syslog_priority  | LOG_INFO              |
+-------------------------------+-----------------------+
```

The values of these variables can be changed by an administrator with the `SUPER` privilege, using the SET statement. Below is an example of how to disable audit logging:

```
SET GLOBAL server_audit_logging=OFF;
```

Although it is possible to change all of the variables shown above, some of them may be reset when the server restarts. Therefore, you may want set them in the configuration file (e.g., `/etc/my.cnf.d/server.cnf`) to ensure the values are the same after a restart:

```
[server]
...
server_audit_logging=OFF
…
```

For the reason given in the paragraph above, you would not generally set variables related to the auditing plugin using the `SET` statement. However, you might do so to test settings before making them more permanent. Since one cannot always restart the server, you would use the `SET` statement to change immediately the variables and then include the same settings in the configuration file so that the variables are set again as you prefer when the server is restarted.

Configuring Logs and Setting Other Variables

Of all of the server variables you can set, you may want to set initially the server_audit_events variable to tell the Audit Plugin which events to log. The Log Settings documentation page describes in detail the choices you have and provides examples of log entries related to them.

You can see a detailed list of system variables related to the MariaDB Audit Plugin on the System Variables documentation page. Status variables related to the Audit Plugin are listed and explained on the Status Variables documentation page.

This page is licensed: CC BY-SA / Gnu FDL

Audit Plugin Log Settings

Events that are logged by the MariaDB Audit Plugin are grouped generally into different types: connect, query, and table events. To log based on these types of events, set the variable, server_audit_events to `CONNECT`, `QUERY`, or `TABLE`. To have the Audit Plugin log more than one type of event, put them in a comma-separated list like so:

```
SET GLOBAL server_audit_events = 'CONNECT,QUERY,TABLE';
```

You can put the equivalent of this in the configuration file like so:

```
[mysqld]
...
server_audit_events=connect,query
```

By default, logging is set to `OFF`. To enable it, set the server_audit_logging variable to `ON`. Note that if the query cache is enabled, and a query is returned from the query cache, no `TABLE` records will appear in the log since the server didn't open or access any tables and instead relied on the cached results. So you may want to disable query caching.

There are a few types of events that may be logged, not just the three common ones mentioned above. A full list of related system variables is detailed on the Server_Audit System Variables page, and status variables on the Server_Audit System Variables page of this documentation. Some of the major ones are highlighted below:

Type	Description
CONNECT	Connects, disconnects and failed connects—including the error code.
QUERY	Queries executed and their results in plain text, including failed queries due to syntax or permission errors.
TABLE	Tables affected by query execution.
QUERY_DDL	Similar to `QUERY`, but filters only DDL-type queries (`CREATE`, `ALTER`, `DROP`, `RENAME` and `TRUNCATE`). There are some exceptions however. `RENAME USER` is not logged, while `CREATE/DROP [PROCEDURE / FUNCTION / USER]` are logged.
QUERY_DML	Similar to `QUERY`, but filters only DML-type queries (`DO`, `CALL`, `LOAD DATA/XML`, `DELETE`, `INSERT`, `SELECT`, `UPDATE`, `HANDLER`, and `REPLACE` statements).
QUERY_DML_NO_SELECT	Similar to `QUERY_DML`, but doesn't log `SELECT` queries.
QUERY_DCL	Similar to `QUERY`, but filters only DCL-type queries (`CREATE USER`, `DROP USER`, `RENAME USER`, `GRANT`, `REVOKE` and `SET PASSWORD` statements).

Since there are other types of queries besides DDL and DML, using the `QUERY_DDL` and `QUERY_DML` options together is not equivalent to using `QUERY`. There is the `QUERY_DCL` option for logging DCL types of queries (e.g., and `GRANT``REVOKE` statements). In the same version, the server_audit_query_log_limit variable was added to be able to set the length of a log record. Previously, a log entry would be truncated due to long query strings.

Logging Connect Events

If the Audit Plugin has been configured to log connect events, it will log connects, disconnects, and failed connects. For a failed connection, the log includes the error code.

It's possible to define a list of users for which events can be excluded or included for tracing their database activities. This list will be ignored, though, for the logging of connect events. This is because auditing standards distinguish between technical and physical users. Connects need to be logged for all types of users; access to objects needs to be logged only for physical users.

Logging Query Events

If `QUERY`, `QUERY_DDL`, `QUERY_DML`, `QUERY_DML_NO_SELECT`, and/or `QUERY_DCL` event types are enabled, then the corresponding types of queries that are executed will be logged for defined users. The queries will be logged exactly as they are executed, in plain text. This is a security vulnerability: anyone who has access to the log files will be able to read the queries. So make sure that only trusted users have access to the log files and that the files are in a protected location. An alternative is to use the `TABLE` event type instead of the query-related event types.

Queries are also logged if they cannot be executed or if they're unsuccessful. For example, a query will be logged because of a syntax error or because the user doesn't have the privileges necessary to access an object. These queries can be parsed by the error code that's provided in the log.

You may find failed queries to be more interesting: They can reveal problems with applications (e.g., an SQL statement in an application that doesn't match the current schema). They can also reveal if a malicious user is guessing at the names of tables and columns to try to get access to data.

Below is an example in which a user attempts to execute an `UPDATE` statement on a table for which he does not have permission:

```
UPDATE employees
SET salary = salary * 1.2
WHERE emp_id = 18236;

ERROR 1142 (42000):
UPDATE command denied to user 'bob'@'localhost' for table 'employees'
```

Looking in the Audit Plugin log (`server_audit.log`) for this entry, you can see the following entry:

```
20170817 11:07:18,ip-172-30-0-38,bob,localhost,15,46,QUERY,company,'UPDATE employees SET salary = salary
* 1.2 WHERE emp_id = 18236',1142
```

This log entry contains the date and time of the query, followed by the server host, and the user and host for the account.

> **Note:**
>
> From MariaDB 12.0, in addition to the host, the audit log also contains the port, where applicable (for instance, connecting via a Unix socket doesn't use a port).

Next is the connection and query identification numbers (i.e., `15` and `46`). After the log event type (i.e., `QUERY`), the database name (i.e., `company`), the query, and the error number are recorded.

Notice that the last value in the log entry is `1142` . That's the error number for the query. To find failed queries, you would look for two elements: the notation indicating that it's an entry `QUERY` and the last value for the entry. If the query is successful, the value will be `0` .

Queries Not Included in Subordinate Query Event Types

Note that the `QUERY` event type will log queries that are not included in any of the subordinate `QUERY_*` event types, such as:

- CREATE FUNCTION
- DROP FUNCTION
- CREATE PROCEDURE
- DROP PROCEDURE
- SET
- CHANGE MASTER TO
- FLUSH
- KILL
- CHECK
- OPTIMIZE
- LOCK
- UNLOCK

- ANALYZE
- INSTALL PLUGIN
- UNINSTALL PLUGIN
- INSTALL SONAME
- UNINSTALL SONAME
- EXPLAIN

Logging Table Events

MariaDB has the ability to record table events in the logs—this is not a feature of MySQL. This feature is the only way to log which tables have been accessed through a view, a stored procedure, a stored function, or a trigger. Without this feature, a log entry for a query shows only the view, stored procedure or function used, not the underlying tables. Of course, you could create a custom application to parse each query executed to find the SQL statements used and the tables accessed, but that would be a drain on system resources. Table event logging is much simpler: it adds a line to the log for each table accessed, without any parsing. It includes notes as to whether it was a read or a write.

If you want to monitor user access to specific databases or tables (e.g., `mysql.user`), you can search the log for them. Then if you want to see a query which accessed a certain table, the audit log entry will include the query identification number. You can use it to search the same log for the query entry. This can be useful when searching a log containing tens of thousands of entries.

Because of the `TABLE` option, you may disable query logging and still know who accessed which tables. You might want to disable `QUERY` event logging to prevent sensitive data from being logged. Since *table* event logging will log who accessed which table, you can still watch for malicious activities with the log. This is often enough to fulfill auditing requirements.

Below is an example with both `TABLE` and `QUERY` events logging. For this scenario, suppose there is a VIEW in which columns are selected from a few tables in a `company` database. The underlying tables are related to sensitive employee information, in particular salaries. Although we may have taken precautions to ensure that only certain user accounts have access to those tables, we will monitor the Audit Plugin logs for anyone who queries them—directly or indirectly through a view.

```
20170817 16:04:33,ip-172-30-0-38,root,localhost,29,913,READ,company,employees,
20170817 16:04:33,ip-172-30-0-38,root,localhost,29,913,READ,company,employees_salaries,
20170817 16:04:33,ip-172-30-0-38,root,localhost,29,913,READ,company,ref_job_titles,
20170817 16:04:33,ip-172-30-0-38,root,localhost,29,913,READ,company,org_departments,
20170817 16:04:33,ip-172-30-0-38,root,localhost,29,913,QUERY,company,
'SELECT * FROM employee_pay WHERE title LIKE \'%Executive%\'  OR title LIKE \'%Manager%\'',0
```

Although the user executed only one SELECT statement, there are multiple entries to the log: one for each table accessed and one entry for the query on the view, (i.e., `employee_pay`). We know primarily this is all for one query because they all have the same connection and query identification numbers (i.e., `29` and `913`).

Logging User Activities

The Audit Plugin will log the database activities of all users, or only the users that you specify. A database activity is defined as a *query* event or a *table* event. *Connect* events are logged for all users.

You may specify users to include in the log with the `server_audit_incl_users` variable or exclude users with the `server_audit_excl_users` variable. This can be useful if you would like to log entries, but are not interested in entries from trusted applications and would like to exclude them from the logs.

You would typically use either the `server_audit_incl_users` variable or the `server_audit_excl_users` variable. You may, though, use both variables. If a username is inadvertently listed in both variables, database activities for that user will be logged because `server_audit_incl_users` takes priority.

Although MariaDB considers a user as the combination of the username and hostname, the Audit Plugin logs only based on the username. MariaDB uses both the username and hostname so as to grant privileges relevant to the location of the user. Privileges are not relevant though for tracing the access to database objects. The host name is still recorded in the log, but logging is not determined based on that information.

The following example shows how to add a new username to the `server_audit_incl_users` variable without removing previous usernames:

```
SET GLOBAL server_audit_incl_users = CONCAT(@@global.server_audit_incl_users, ',Maria');
```

Remember to add also any new users to be included in the logs to the same variable in MariaDB configuration file. Otherwise, when the server restarts it will discard the setting.

Excluding or Including Users

By default events from all users are logged, but certain users can be excluded from logging by using the `server_audit_excl_users` variable. For example, to exclude users *valerianus* and *rocky* from having their events logged:

```
server_audit_excl_users=valerianus,rocky
```

This option is primarily used to exclude the activities of trusted applications.

Alternatively, `server_audit_incl_users` can be used to specifically include users. Both variables can be used, but if a user appears on both lists, `server_audit_incl_users` has a higher priority, and their activities will be logged.

> **Note:**
>
> Note that `CONNECT` events are always logged for all users, regardless of these two settings. Logging is also based on username only, not the username and hostname combination that MariaDB uses to determine privileges.

This page is licensed: CC BY-SA / Gnu FDL

Audit Plugin Location and Rotation of Logs

Logs can be written to a separate file or to the system logs. If you prefer to have the logging separated from other system information, the value of the variable server_audit_output_type should be set to `file`. Incidentally, `file` is the only option on Windows systems.

You can force a rotation by enabling the server_audit_file_rotate_now variable like so:

```
SET GLOBAL server_audit_file_rotate_now = ON;
```

Separate log files

In addition to setting `server_audit_output_type`, you will have to provide the file path and name of the audit file. This is set in the variable server_audit_file_path. You can set the file size limit of the log file with the variable server_audit_file_rotate_size.

So, if rotation is on and the log file has reached the size limit you set, a copy is created with a consecutive number as extension the original file will be truncated to be used for the auditing again. To limit the number of log files created, set the variable server_audit_file_rotations. You can force log file rotation by setting the variable server_audit_file_rotate_now to a value of `ON`. When the number of files permitted is reached, the oldest file will be overwritten. Here is how those variables might be set in a server configuration file:

```
[mysqld]
...
server_audit_file_rotate_now=ON
server_audit_file_rotate_size=1000000
server_audit_file_rotations=5
...
```

System logs

For security reasons, it's better sometimes to use the system logs instead of a local file owned by the `mysql` user. To do this, the value of server_audit_output_type needs to be set to `syslog`. Advanced configurations, such as using a remote `syslogd` service, are part of the `syslogd` configuration.

The variables,server_audit_syslog_ident and server_audit_syslog_info can be used to identify a system log entry made by the audit plugin. If a remote `syslogd` service is used for several MariaDB servers, these same variables are also used to identify the MariaDB server.

Here is a system log entry taken from a server which had server_audit_syslog_ident set to the default value of `mysql-server_auditing`, and server_audit_syslog_info set to `<prod1>`.

```
Aug 717:19:58localhostmysql-server_auditing:
<prod1> localhost.localdomain,root,localhost,1,7,
QUERY, mysql, 'SELECT * FROM user',0
```

Although the default values for server_audit_syslog_facility and server_audit_syslog_priority should be sufficient in most cases. They can be changed based on the definition in `syslog.h` for the functions `openlog()` and `syslog()`.

This page is licensed: CC BY-SA / Gnu FDL

Audit Plugin Log Format

The audit plugin logs user access to MariaDB and its objects. The audit trail (that is, the audit log) is a set of records, written as a list of fields to a file in a plain-text format. The fields in the log are separated by commas. The format used for the plugin's own log file is slightly different from the format used if it logs to the system log because it has its own standard format.

Formal Specification

When the MariaDB Audit Plugin (v1) writes to a dedicated file, it uses a comma-separated (CSV) format. For tool developers, it is essential to map the `connectionid` to the server's global connection identifier to enable cross-log analysis.

Template: `<timestamp>,<serverhost>,<username>,<host>,<connectionid>,<queryid>,<operation>,<database>,<object>,<retcode>`

Field	Component	Data Type	Standardized Name / Description
1	`timestamp`	`DateTime`	Formatted as `%Y%m%d %H:%i:%s` (the default), or as specified in server_audit_timestamp_format.
2	`serverhost`	`String`	Hostname of the originating server.
5	`connectionid`	`Unsigned Int`	Standardized: Thread ID. Matches the `Thread ID` in Error, General, and Slow logs.
6	`queryid`	`Unsigned Int`	A unique identifier for the specific query, used to correlate `QUERY` and `TABLE` events.
7	`operation`	`String`	Action type (e.g., `CONNECT`, `QUERY`, `READ`, `WRITE`).

Field	Component	Data Type	Standardized Name / Description
10	`retcode`	`Integer`	Result code (`0` for success).

Audit Log Format with Syslog

If `server_audit_output_type` is set to `SYSLOG`, the standard CSV line is prefixed with syslog metadata: `<timestamp> <syslog_host> <syslog_ident>: <syslog_info> [Standard CSV Fields]`

Various events result in different audit records. Some events do not return a value for some fields (for instance, when the active database is not set when connecting to the server).

Below is a generic example of the output for connect events, with placeholders representing data. These are events in which a user connected, disconnected, or tried unsuccessfully to connect to the server.

```
[timestamp],[serverhost],[username],[host],[connectionid],0,CONNECT,[database],,0
[timestamp],[serverhost],[username],[host],[connectionid],0,DISCONNECT,,,0
[timestamp],[serverhost],[username],[host],[connectionid],0,FAILED_CONNECT,,,[retcode]
```

Here is the one audit record generated for each query event:

```
[timestamp],[serverhost],[username],[host],[connectionid],[queryid],QUERY,[database],[object], [retcode]
```

Below are generic examples of records that are entered in the audit log for each type of table event:

```
[timestamp],[serverhost],[username],[host],[connectionid],[queryid],CREATE,[database],[object],
[timestamp],[serverhost],[username],[host],[connectionid],[queryid],READ,[database],[object],
[timestamp],[serverhost],[username],[host],[connectionid],[queryid],WRITE,[database],[object],
[timestamp],[serverhost],[username],[host],[connectionid],[queryid],ALTER,[database],[object],
[timestamp],[serverhost],[username],[host],[connectionid],[queryid],RENAME,[database],
[object_old]|[database_new].[object_new],
[timestamp],[serverhost],[username],[host],[connectionid],[queryid],DROP,[database],[object],
```

Passwords are hidden in the log for certain types of queries. They are replaced with asterisks for `GRANT`, `CREATE USER`, `CREATE MASTER`, `CREATE SERVER`, and `ALTER SERVER` statements. Passwords, however, are not replaced for the `PASSWORD()` and `OLD_PASSWORD()` functions when they are used inside other SQL statements (i.e., `SET PASSWORD`).

> **CURRENT**
>
> For Galera Cluster replication applier operations, audit log plugin logs events with a generic name of `<wsrep_applier>`.
>
> This addresses an issue where the user was logged on the primary node, but stripped from other cluster nodes. See MDEV-35511 for details.
>
> **< 10.11.16**
>
> For Galera Cluster replication applier operations, audit log plugin logs events without indicating what user initiates them.

Audit Plugin Options and System Variables

Overview

There are a several options and system variables related to the MariaDB Audit Plugin, once it has been installed. System variables can be displayed using the SHOW VARIABLES statement like so:

```
SHOW GLOBAL VARIABLES LIKE 'server_audit%';
+-------------------------------+-----------------------+
| Variable_name                 | Value                 |
+-------------------------------+-----------------------+
| server_audit_events           |                       |
| server_audit_excl_users       |                       |
| server_audit_file_buffer_size | 0                     |
| ...                           | ...                   |
| server_audit_syslog_priority  | LOG_INFO              |
| server_audit_timestamp_format | %Y%m%d %H:%i:%s       |
+-------------------------------+-----------------------+
```

To change the value of one of these variables, you can use the `SET` statement, or set them at the command-line when starting MariaDB. It's recommended that you set them in the MariaDB configuration for the server like so:

```
[mariadb]
...
server_audit_excl_users='bob,ted'
...
```

System Variables

Below is a list of all system variables related to the Audit Plugin. See Server System Variables for a complete list of system variables and instructions on setting them. See also the full list of MariaDB options, system and status variables.

`server_audit_events`

- Description: If set, this restricts audit logging to certain event types. If not set, every event type is logged to the audit log.
- Command line: `--server-audit-events=value`
- Scope: Global
- Dynamic: Yes
- Data type: `string`
- Default value: Empty string
- Valid values:
  - `CONNECT`, `QUERY`, `TABLE` (MariaDB Audit Plugin < 1.2.0)
  - `CONNECT`, `QUERY`, `TABLE`, `QUERY_DDL`, `QUERY_DML` (MariaDB Audit Plugin >= 1.2.0)
  - `CONNECT`, `QUERY`, `TABLE`, `QUERY_DDL`, `QUERY_DML`, `QUERY_DCL` (MariaDB Audit Plugin >=1.3.0)
  - `CONNECT`, `QUERY`, `TABLE`, `QUERY_DDL`, `QUERY_DML`, `QUERY_DCL`, `QUERY_DML_NO_SELECT` (MariaDB Audit Plugin >= 1.4.4)
  - Consult MariaDB Audit Plugin - Versions for a list of MariaDB releases and their corresponding Audit Plugin versions.

`server_audit_excl_users`

- Description: If not empty, it contains the list of users whose activity will NOT be logged: `SET GLOBAL server_audit_excl_users='user_foo, user_bar'`. CONNECT records aren't affected by this variable - they are always logged. The user is still logged if it's specified in server_audit_incl_users.

- Command line: `--server-audit-excl-users=value`
- Scope: Global
- Dynamic: Yes
- Data type: `string`
- Default value: Empty string
- Size limit: 1024 characters

`server_audit_file_buffer_size`

- Description: Size (in bytes) of file buffer to make logging faster. Values > `0` are adjusted in increments of `8192`. (For instance, a value of `100` would be adjusted to `8192`.)
- Command line: `--server-audit-file-buffer-size= #`
- Scope: Global
- Dynamic: Yes
- Data type: `numeric`
- Value range: `0` to `65536`
- Default value: `0` (no buffering)
- Introduced: MariaDB 12.1
- Usage: See description

`server_audit_file_path`

- Description: When server_audit_output_type=file, sets the path and the filename to the log file. If the specified path exists as a directory, then the log will be created inside that directory with the name 'server_audit.log'. Otherwise the value is treated as a filename. The default value is 'server_audit.log', which means this file will be created in the database directory.
- Command line: `--server-audit-file-path=value`
- Scope: Global
- Dynamic: Yes
- Data type: `string`
- Default value: `server_audit.log`

`server_audit_file_rotate_now`

- Description: When server_audit_output_type=file, the user can force the log file rotation by setting this variable to ON or 1.
- Command line: `--server-audit-rotate-now[={0|1}]`
- Scope: Global
- Dynamic: Yes
- Data type: `boolean`
- Default value: `OFF`

`server_audit_file_rotate_size`

- Description: When server_audit_output_type=file, it limits the size of the log file to the given amount of bytes. Reaching that limit turns on the rotation - the current log file is renamed as 'file_path.1'. The empty log file is created as 'file_path' to log into it. The default value is 1000000.
- Command line: `--server-audit-rotate-size=#`
- Scope: Global
- Dynamic: Yes

- Data Type: `numeric`
- Default Value: `1000000`
- Range: `100` to `9223372036854775807`

`server_audit_file_rotations`

- Description: When server_audit_output_type=file', this specifies the number of rotations to save. If set to 0 then the log never rotates. The default value is 9.
- Command line: `--server-audit-rotations=#`
- Scope: Global
- Dynamic: Yes
- Data type: `numeric`
- Default value: `9`
- Range: `0` to `999`

`server_audit_incl_users`

- Description: If not empty, it contains a comma-delimited list of users whose activity will be logged: `SET GLOBAL server_audit_incl_users='user_foo, user_bar'`. CONNECT records aren't affected by this variable - they are always logged. This setting has higher priority than server_audit_excl_users. So if the same user is specified both in incl_ and excl_ lists, they will still be logged.
- Command line: `--server-audit-incl-users=value`
- Scope: Global
- Dynamic: Yes
- Data type: `string`
- Default value: Empty string
- Size limit: 1024 characters

`server_audit_loc_info`

- Description: Used by plugin internals. It has no useful meaning to users.
  - In earlier versions, users see it as a read-only variable.
  - In later versions, it is hidden from the user.
- Command line: N/A
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: Empty string

`server_audit_logging`

- Description: Enables/disables the logging. Expected values are ON/OFF: `SET GLOBAL server_audit_logging=on` If the server_audit_output_type is FILE, this will actually create/open the logfile so the server_audit_file_path should be properly specified beforehand. Same about the `SYSLOG`-related parameters. The logging is turned off by default.
- Command line: `--server-audit-logging[={0|1}]`
- Scope: Global
- Dynamic: Yes
- Data type: `boolean`

- Default value: `OFF`

`server_audit_mode`

- Description: This variable doesn't have any distinctive meaning for a user. Its value mostly reflects the server version with which the plugin was started and is intended to be used by developers for testing.
- Command line: `--server-audit-mode[=#]`
- Scope: Global
- Dynamic: Yes
- Data type: `numeric`
- Default value: `0`
- Range: `0` to `1`

`server_audit_output_type`

- Description: Specifies the desired output type. Can be SYSLOG, FILE or null as no output: `SET GLOBAL server_audit_output_type=file` file: log records will be saved into the rotating log file. The name of the file set by server_audit_file_path variable. syslog: log records will be sent to the local syslogd daemon with the standard <syslog.h> API. The default value is 'file'.
- Command line: `--server-audit-output-type=value`
- Scope: Global
- Dynamic: Yes
- Data type: `enum`
- Default value: `file`
- Valid values: `SYSLOG`, `FILE`

`server_audit_query_log_limit`

- Description: Limit on the length of the query string in a record.
- Command line: `--server-audit-query-log-limit=#`
- Scope: Global
- Dynamic: Yes
- Data type: `numeric`
- Default value: `1024`
- Range: `0` to `2147483647`

`server_audit_sync_log_file`

- Description: Flushes the buffer to the log file.
  While log records are in the buffer, they don't appear in the log file. To write them out from the buffer, issue this statement:
  `SET GLOBAL server_audit_sync_log_file=1`
- Command line: `--server-audit-sync-log-file`
- Scope: Global
- Dynamic: Yes
- Data type: N/A
- Default value: `OFF`
- Valid values: `ON` (or `1`), `OFF` (or `0`)
- Introduced: MariaDB 12.1
- Usage: See description

`server_audit_syslog_facility`

- Description: SYSLOG-mode variable. It defines the ‘facility’ of the records that will be sent to the syslog. Later the log can be filtered by this parameter.
- Command line: `--server-audit-syslog-facility=value`
- Scope: Global
- Dynamic: Yes
- Data type: `enum`
- Default value: `LOG_USER`
- Valid values: `LOG_USER`, `LOG_MAIL`, `LOG_DAEMON`, `LOG_AUTH`, `LOG_SYSLOG`, `LOG_LPR`, `LOG_NEWS`, `LOG_UUCP`, `LOG_CRON`, `LOG_AUTHPRIV`, `LOG_FTP`, and `LOG_LOCAL0` – `LOG_LOCAL7`.

`server_audit_syslog_ident`

- Description: SYSLOG-mode variable. String value for the ‘ident’ part of each syslog record. Default value is ‘mysql-server_auditing’. New value becomes effective only after restarting the logging.
- Command line: `--server-audit-syslog-ident=value`
- Scope: Global
- Dynamic: Yes
- Data type: `string`
- Default value: `mysql-server_auditing`

`server_audit_syslog_info`

- Description: SYSLOG-mode variable. The ‘info’ string to be added to the syslog records. Can be changed any time.
- Command line: `--server-audit-syslog-info=value`
- Scope: Global
- Dynamic: Yes
- Data type: `string`
- Default value: Empty string

`server_audit_syslog_priority`

- Description: SYSLOG-mode variable. Defines the priority of the log records for the syslogd.
- Command line: `--server-audit-syslog-priority=value`
- Scope: Global
- Dynamic: Yes
- Data type: `enum`
- Default value: `LOG_INFO`
- Valid values: `LOG_EMERG`, `LOG_ALERT`, `LOG_CRIT`, `LOG_ERR`, `LOG_WARNING`, `LOG_NOTICE`, `LOG_INFO`, `LOG_DEBUG`

`server_audit_timestamp_format`

- Description: A format string used to print the timestamp into the audit log messages. The format used is the same as DATE_FORMAT.
- Command line: `--server-audit-timestamp-format=value`
- Scope: Global
- Dynamic: Yes

- Data type: `string`
- Default value: `%Y%m%d %H:%i:%s`

Notes on System Variables

audit_file_buffer_size and server_audit_sync_log_file

The server audit plugin typically employs synchronous, per-event logging, causing performance bottlenecks. Individual file writes for each log entry can result in significant I/O overhead, especially in large database environments. As of MariaDB 12.1, two new variables were introduced to allow asynchronous logging, and more fine grained control over how audit log writes are handled. Using the `server_audit_file_buffer_size` setting (buffer size in bytes), you can configure an additional in-memory audit log buffer. When the size of the buffer exceeds the `server_audit_file_buffer_size` setting, the audit log is written to disk. Additionally, a manual on-demand audit log disk sync can be triggered by setting `server_audit_sync_log_file` to `ON` or `1`.

Options

`server_audit`

- Description: Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGINwhile the server is running.
  - See MariaDB Audit Plugin - Installation: Prohibiting Uninstallation for more information.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- Command line: `--server-audit=val`
- Data Type: `enumerated`
- Default Value: `ON`
- Valid Values: `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

This page is licensed: CC BY-SA / Gnu FDL

Audit Plugin Status Variables

There are a few status variables related to the MariaDB Audit Plugin, once it has been installed. These variables can be displayed using the SHOW STATUS statement like so:

```
SHOW STATUS LIKE 'server_audit%';

+----------------------------+------------------+
| Variable_name              | Value            |
+----------------------------+------------------+
| Server_audit_active        | ON               |
| Server_audit_current_log   | server_audit.log |
| Server_audit_last_error    |                  |
| Server_audit_writes_failed | 0                |
+----------------------------+------------------+
```

Status Variables

Below is a list of all status variables related to the Audit Plugin. These cannot be set: These are not to be confused with system variables, which can be set. See Server Status Variables for a complete list of status variables that can be viewed with the SHOW STATUS statement. See also the Full list of MariaDB options, system and status variables.

`Server_audit_active`

- Description: If the auditing is actually working. It gets the ON value when the logging is successfully started. Then it can get the OFF value if the logging was stopped or log records can't be properly stored due to file or syslog errors.
- Data Type: `boolean`

`Server_audit_current_log`

- Description: The name of the logfile or the SYSLOG parameters that are in current use.
- Data Type: `string`

`Server_audit_last_error`

- Description: If something went wrong with the logging here you can see the message.
- Data Type: `string`

`Server_audit_writes_failed`

- Description: The number of log records since last logging-start that weren't properly stored because of errors of any kind. The global value can be flushed by FLUSH STATUS.
- Data Type: `numeric`
- Default Value: `0`

This page is licensed: CC BY-SA / Gnu FDL

Audit Plugin Versions

Below is a list of the releases of the MariaDB Audit Plugin, the most recent version first, and in which versions of MariaDB each plugin version was included.

MariaDB Community Audit Plugin Version	Introduced in MariaDB Community Server
1.5.0	MariaDB 12.0.1
1.4.14	MariaDB 10.3.35, MariaDB 10.4.25, MariaDB 10.5.16, MariaDB 10.6.8, MariaDB 10.7.4
1.4.13	MariaDB 10.2.38, MariaDB 10.3.29, MariaDB 10.4.19, MariaDB 10.5.10
1.4.10	MariaDB 10.2.35, MariaDB 10.3.26, MariaDB 10.5.7
1.4.7	MariaDB 10.1.41, MariaDB 10.2.26, MariaDB 10.3.17, MariaDB 10.4.7
1.4.5	MariaDB 10.2.24, MariaDB 10.3.15, MariaDB 10.4.5
1.4.4	MariaDB 5.5.61, MariaDB 10.0.36, MariaDB 10.1.34, MariaDB 10.2.15, MariaDB 10.3.7, MariaDB 10.4.0
1.4.0	MariaDB 5.5.48, MariaDB 10.0.24, MariaDB 10.1.11
1.3.0	MariaDB 5.5.43, MariaDB 10.0.18, MariaDB 10.1.5
1.2.0	MariaDB 5.5.42, MariaDB 10.0.17, MariaDB 10.1.4
1.1.7	MariaDB 5.5.38, MariaDB 10.0.11, MariaDB 10.1.0

MariaDB Community Audit Plugin Version	Introduced in MariaDB Community Server
1.1.6	MariaDB 5.5.37, MariaDB 10.0.10
1.1.5	MariaDB 10.0.09
1.1.4	MariaDB 5.5.36
1.1.3	MariaDB 5.5.34, MariaDB 10.0.7

This page is licensed: CC BY-SA / Gnu FDL

Authentication Plugins

See Pluggable Authentication Overview.

Pluggable authentication allows MariaDB to use various authentication methods, enabling external validation, different hashing algorithms, and role-based access control.

See Authentication Plugin - caching_sha2_password.

MySQL-compatible caching_sha2_password authentication plugin, for migrating MySQL users to MariaDB without changing their passwords (migration use; PARSEC is recommended otherwise).

See Authentication Plugin - ed25519.

The ed25519 authentication plugin provides high-security password authentication using the Elliptic Curve Digital Signature Algorithm, a modern alternative to SHA-1.

See Authentication Plugin - GSSAPI.

Complete GSSAPI authentication setup: Kerberos/SSPI single sign-on, INSTALL SONAME ‘auth_gssapi’, gssapi_keytab_path/principal_name, CREATE USER syntax.

See Authentication Plugin - mysql_native_password.

Complete Authentication Plugin - mysql_native_password guide for MariaDB. Complete reference documentation for implementation, configuration, and usage.

See Authentication Plugin - mysql_old_password.

This plugin provides backward compatibility for pre-4.1 clients using an older, insecure password hashing algorithm and should not be used for new installations.

See Authentication Plugin - Named Pipe.

The named_pipe authentication plugin allows Windows users connecting via named pipes to authenticate using their operating system credentials without a password.

See Authentication Plugin - PARSEC.

PARSEC is a modern, secure authentication plugin that uses salted passwords and elliptic curve cryptography to prevent replay attacks and secure user credentials.

See Authentication Plugin - SHA-256.

The SHA-256 authentication plugin uses the SHA-256 hashing algorithm for password storage, offering stronger security than the default SHA-1 method.

See Authentication Plugin - Unix Socket.

Official Unix socket authentication: OS user login via SO_PEERCRED/uid matching, CREATE USER IDENTIFIED VIA unix_socket, and unix_socket force modes.

See Authentication with Pluggable Authentication Modules (PAM).

Learn about authentication with Pluggable Authentication Modules (PAM) in MariaDB Server. This section details how to integrate MariaDB with PAM for centralized and flexible user authentication.

This page is licensed: CC BY-SA / Gnu FDL

Pluggable Authentication Overview

When a user attempts to log in, the authentication plugin controls how MariaDB Server determines whether the connection is from a legitimate user.

When creating or altering a user account with the GRANT, CREATE USER or ALTER USER statements, you can specify the authentication plugin you want the user account to use, by providing the `IDENTIFIED VIA` clause. By default, when you create a user account without specifying an authentication plugin, MariaDB uses the mysql_native_password plugin.

> **Tip:**
>
> You can specify multiple authentication plugins for each user account.

The `root@localhost` user created by mariadb-install-db has the ability to use two authentication plugins:

1. It is configured to try to use the unix_socket authentication plugin. This allows the `root@localhost` user to log in without a password via the local Unix socket file defined by the socket system variable, as long as the login is attempted from a process owned by the operating system `root` user account.
2. If authentication fails with the unix_socket authentication plugin, it is configured to try to use the mysql_native_password authentication plugin. However, an invalid password is initially set, so in order to authenticate this way, a password must be set with SET PASSWORD.

Supported Authentication Plugins

The authentication process is a conversation between the server and a client. MariaDB implements both server-side and client-side authentication plugins.

Supported Server Authentication Plugins

MariaDB provides nine server-side authentication plugins:

- mysql_native_password
- mysql_old_password
- ed25519
- gssapi
- pam (Unix only)
- unix_socket (Unix only)
- named_pipe (Windows only)
- PARSEC (from MariaDB Community Server 11.6 and MariaDB Enterprise Server 11.8)
- caching_sha2_password (from MariaDB Community Server 12.1 and MariaDB Enterprise Server 11.8)

Supported Client Authentication Plugins

MariaDB provides eight client-side authentication plugins:

- mysql_native_password
- mysql_old_password
- client_ed25519

- auth_gssapi_client
- dialog
- mysql_clear_password
- sha256_password
- caching_sha2_password

Options Related to Authentication Plugins

Server Options Related to Authentication Plugins

MariaDB supports the following server options related to authentication plugins:

Server Option	Description
old_passwords={1 | 0}	If set to `1` (`0` is default), MariaDB reverts to using the mysql_old_password authentication plugin by default for newly created users and passwords, instead of the mysql_native_password authentication plugin.
plugin_dir=path	Path to the plugin directory. For security reasons, either make sure this directory can only be read by the server, or set secure_file_priv.
plugin_maturity=level	The lowest acceptable plugin maturity. MariaDB will not load plugins less mature than the specified level.
secure_auth	Connections will be blocked if they use the mysql_old_password authentication plugin.

Client Options Related to Authentication Plugins

Most clients and utilities support command-line arguments related to client authentication plugins:

Client Option	Description
–connect-expired-password	Notify the server that this client is prepared to handle expired password sandbox mode even if –batch was specified.
–default-auth=name	Default authentication client-side plugin to use.
–plugin-dir=path	Directory for client-side plugins.
–secure-auth	Refuse to connect to the server if the server uses the mysql_old_password authentication plugin. This mode is off by default, which is different from MySQL.

Developers who are using MariaDB Connector/C can implement similar functionality in their application by setting the following options with the mysql_optionsv function:

- `MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS`
- `MYSQL_PLUGIN_DIR`
- `MYSQL_DEFAULT_AUTH`
- `MYSQL_SECURE_AUTH`

For example:

```
mysql_optionsv(mysql, MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS, 1);
mysql_optionsv(mysql, MYSQL_DEFAULT_AUTH, "name");
mysql_optionsv(mysql, MYSQL_PLUGIN_DIR, "path");
mysql_optionsv(mysql, MYSQL_SECURE_AUTH, 1);
```

Installation Options Related to Authentication Plugins

mariadb-install-db supports the following installation options related to authentication plugins:

Installation Option	Description
–auth-root-authentication-method={normal | socket}	If set to `normal` (the default), it creates a `root@localhost` account that authenticates with the mysql_native_password authentication plugin and that has no initial password set, which can be insecure. If set to `socket`, it creates a `root@localhost` account that authenticates with the unix_socket authentication plugin. Set to `normal` by default.
–auth-root-socket-user=USER	Used with `--auth-root-authentication-method=socket`. It specifies the name of the second account to create with SUPER privileges in addition to root, as well as of the system account allowed to access it. Defaults to the value of `--user`.

Extended SQL Syntax

MariaDB has extended the SQL standard GRANT, CREATE USER, and ALTER USER statements, so that they support specifying different authentication plugins for specific users. An authentication plugin can be specified with these statements by providing the `IDENTIFIED VIA` clause. Examples:

```
GRANT <privileges> ON <level> TO <user>
   IDENTIFIED VIA <plugin> [ USING <string> ]
```

```
CREATE USER <user>
   IDENTIFIED VIA <plugin> [ USING <string> ]
```

```
ALTER USER <user>
   IDENTIFIED VIA <plugin> [ USING <string> ]
```

The optional `USING` clause allows users to provide an authentication string to a plugin. The authentication string's format and meaning is completely defined by the plugin.

For example, for the mysql_native_password authentication plugin, the authentication string should be a password hash:

```
CREATE USER mysqltest_up1
   IDENTIFIED VIA mysql_native_password USING '*E8D46CE25265E545D225A8A6F1BAF642FEBEE5CB';
```

Since mysql_native_password is the default authentication plugin, the above is just another way of saying the following:

```
CREATE USER mysqltest_up1
   IDENTIFIED BY PASSWORD '*E8D46CE25265E545D225A8A6F1BAF642FEBEE5CB';
```

In contrast, for the pam authentication plugin, the authentication string should refer to a PAM service name:

```
CREATE USER mysqltest_up1
   IDENTIFIED VIA pam USING 'mariadb';
```

A user account can be associated with multiple authentication plugins.

To configure the `root@localhost` user account to try the unix_socket authentication plugin, followed by the mysql_native_password authentication plugin as a backup, execute the following query:

```
CREATE USER root@localhost
   IDENTIFIED VIA unix_socket
   OR mysql_native_password USING PASSWORD("verysecret");
```

See Authentication for more information.

Authentication Plugins Installed by Default

Server Authentication Plugins Installed by Default

Not all server-side authentication plugins are installed by default. If a specific server-side authentication plugin is not installed by default, then you can find the installation procedure on the documentation page for the specific authentication plugin.

The following server-side authentication plugins are installed by default:

- The mysql_native_password and mysql_old_password authentication plugins authentication plugins are installed by default in all builds.
- The unix_socket authentication plugin is installed by default in all builds on Unix and Linux.
- The named_pipe authentication plugin is installed by default in all builds on Windows.

The following server-side authentication plugins are installed by default:

- The mysql_native_password and mysql_old_password authentication plugins are installed by default in all builds.
- The unix_socket authentication plugin is installed by default in new installations that use the .deb packages provided by Debian's default repositories and Ubuntu's default repositories in Ubuntu. See Differences in MariaDB in Debian (and Ubuntu) for more information.
- The named_pipe authentication plugin is installed by default in all builds on Windows.

Client Authentication Plugins Installed by Default

Client-side authentication plugins do not need to be *installed* in the same way that server-side authentication plugins do. If the client uses either the `libmysqlclient` or MariaDB Connector/C library, then the library automatically loads client-side authentication plugins from the library's plugin directory whenever they are needed.

Most clients and utilities support the `--plugin-dir` command line argument that can be used to set the path to the library's plugin directory:

Client Option	Description
–plugin-dir=path	Directory for client-side plugins.

Developers who are using MariaDB Connector/C can implement similar functionality in their application by setting the `MYSQL_PLUGIN_DIR` option with the mysql_optionsv function. Example:

```
mysql_optionsv(mysql, MYSQL_PLUGIN_DIR, "path");
```

If your client encounters errors similar to the following error, you may need to set the path to the library's plugin directory:

```
ERROR 2059 (HY000): Authentication plugin 'dialog' cannot be loaded: /usr/lib/mysql/plugin/dialog.so:
cannot open shared object file: No such file or directory
```

If the client does **not** use either the `libmysqlclient` or MariaDB Connector/C library, then you will have to determine which authentication plugins are supported by the specific client library used by the client.

If the client uses either the `libmysqlclient` or MariaDB Connector/C library, but the client is not bundled with either library's *optional* client authentication plugins, then you can only use the conventional authentication plugins (like mysql_native_password and mysql_old_password) and the non-conventional authentication plugins that don't require special client-side authentication plugins (like unix_socket and named_pipe).

Default Authentication Plugin

Default Server Authentication Plugin

The mysql_native_password authentication plugin is currently the default authentication plugin in all versions of MariaDB if the old_passwords system variable is set to `0`, which is the default.

On a system with the old_passwords system variable set to `0`, this means that if you create a user account with either the GRANT or CREATE USER `statements, and if you do not specify an authentication plugin with the` IDENTIFIED VIA `clause, then MariaDB will use the [mysql_native_password](#pg-tication-plugins-authentication-plugin-mysql-native-password-0a775c07) authentication plugin for the user account.`

Creating a user account like this, it uses the mysql_native_password authentication plugin:

```
CREATE USER username@hostname;
```

The same is true for this user account:

```
CREATE USER username@hostname IDENTIFIED BY 'notagoodpassword';
```

The mysql_old_password authentication plugin becomes the default authentication plugin in all versions of MariaDB, if the old_passwords system variable is explicitly set to `1`.

Important:

The mysql_old_password authentication plugin is not considered secure. It is recommended to avoid using this authentication plugin. To help prevent undesired use of the mysql_old_password authentication plugin, the server supports the secure_auth system variable that configures the server to refuse connections trying to use the mysql_old_password authentication plugin.

Most clients and utilities support `secure_auth`.

Server Option	Description
old_passwords={1 | 0}	If set to `1` (`0` is default), MariaDB reverts to using the mysql_old_password authentication plugin by default for newly created users and passwords, instead of the mysql_native_password authentication plugin.
secure_auth	Connections are blocked if they use the mysql_old_password authentication plugin.

Developers using MariaDB Connector/C can implement similar functionality in their application by setting the `MYSQL_SECURE_AUTH` option with the mysql_optionsv function:

```
mysql_optionsv(mysql, MYSQL_SECURE_AUTH, 1);
```

Default Client Authentication Plugin

The default client-side authentication plugin depends on these factors:

- If a client doesn't explicitly set the default client-side authentication plugin, the client determines which authentication plugin to use, by checking the length of the scramble in the server's handshake packet.
- If the server's handshake packet contains a 9-byte scramble, the client defaults to the mysql_old_password authentication plugin.
- If the server's handshake packet contains a 20-byte scramble, the client defaults to the mysql_native_password authentication plugin.

Setting the Default Client Authentication Plugin

Most clients and utilities support the `--default-auth` command-line argument that sets the default client-side authentication plugin:

Client Option	Description
`--default-auth=name`	Default authentication client-side plugin to use.

Developers using MariaDB Connector/C can implement similar functionality in applications, by setting the `MYSQL_DEFAULT_AUTH` option with the mysql_optionsv function:

```
mysql_optionsv(mysql, MYSQL_DEFAULT_AUTH, "name");
```

If you know that your user account is configured to require a client-side authentication plugin other than mysql_old_password or mysql_native_password, this helps speed up your connection process when you explicitly set the default client-side authentication plugin.

According to the client-server protocol, the server first sends the handshake packet to the client, then the client replies with a packet containing the user name of the user account that is requesting access. The server handshake packet initially tells the client to use the default server authentication plugin, and the client reply initially tells the server that it will use the default client authentication plugin.

However, the server-side and client-side authentication plugins mentioned in these initial packets may not be the correct ones for this specific user account. The server only knows what authentication plugin to use for this specific user account after reading the user name from the client reply packet and finding the appropriate row for the user account in either the mysql.user table or the mysql.global_priv table, depending on the MariaDB version.

If the server finds that either the server-side or client-side default authentication plugin does not match the actual authentication plugin that should be used for the given user account, then the server restarts the authentication on either the server side or the client side.

This means that, if you know what client authentication plugin your user account requires, then you can avoid an unnecessary authentication restart and you can save two packets and two round-trips.between the client and server by configuring your client to use the correct authentication plugin by default.

Available Authentication Plugins

Server Authentication Plugins

`mysql_native_password`

The mysql_native_password authentication plugin uses the same password hashing algorithm used by the PASSWORD() function when old_passwords is set. This hashing algorithm is based on SHA-1.

`mysql_old_password`

The mysql_old_password authentication plugin uses the same hashing algorithm used by the OLD_PASSWORD() function and by the PASSWORD() function when old_passwords=1 is set.

`ed25519`

The ed25519 authentication plugin uses the Elliptic Curve Digital Signature Algorithm to securely store users' passwords and to authenticate users. The ed25519 algorithm is the same one that is used by OpenSSH. It is based on the elliptic curve and code created by Daniel J. Bernstein.

`gssapi`

The gssapi authentication plugin allows authenticating with services that use the Generic Security Services Application Program Interface (GSSAPI). Windows has a slightly different but very similar API called Security Support Provider Interface (SSPI).

On Windows, this authentication plugin supports Kerberos and NTLM authentication. Windows authentication is supported regardless of whether a domain is used in the environment.

On Unix systems, the most dominant GSSAPI service is Kerberos. However, it is less commonly used on Unix systems than it is on Windows. Regardless, this authentication plugin also supports Kerberos authentication on Unix.

The gssapi authentication plugin is most often used for authenticating with Microsoft Active Directory.

`pam`

The pam authentication plugin allows MariaDB to offload user authentication to the system's Pluggable Authentication Module (PAM) framework. PAM is an authentication framework used by Linux, FreeBSD, Solaris, and other Unix-like operating systems.

`unix_socket`

The unix_socket authentication plugin allows the user to use operating system credentials when connecting to MariaDB via the local Unix socket file. This Unix socket file is defined by the socket system variable.

The unix_socket authentication plugin works by calling the getsockopt system call with the `SO_PEERCRED` socket option, which allows it to retrieve the `uid` of the process that is connected to the socket. It is then able to get the user name associated with that `uid`. Once it has the user name, it will authenticate the connecting user as the MariaDB account that has the same user name.

For example:

```
$ mysql -uroot
MariaDB []> CREATE USER serg IDENTIFIED VIA unix_socket;
MariaDB []> CREATE USER monty IDENTIFIED VIA unix_socket;
MariaDB []> quit
Bye
$ whoami
serg
$ mysql --user=serg
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 2
Server version: 5.2.0-MariaDB-alpha-debug Source distribution
MariaDB []> quit
Bye
$ mysql --user=monty
ERROR 1045 (28000): Access denied for user 'monty'@'localhost' (using password: NO)
```

In this example, a user `serg` is already logged into the operating system and has full shell access. The user has already authenticated with the operating system and the MariaDB account is configured to use the unix_socket authentication plugin, so the user does not need to authenticate again for the database. MariaDB accepts the user's operating system credentials and allows connecting. However, any attempt to connect to the database as another operating system user will be denied.

`named_pipe`

The named_pipe authentication plugin allows the user to use operating system credentials when connecting to MariaDB via named pipe on Windows. Named pipe connections are enabled by the named_pipe system variable.

The named_pipe authentication plugin works by using named pipe impersonation and calling `GetUserName()` to retrieve the user name of the process that is connected to the named pipe. Once it has the user name, it authenticates the connecting user as the MariaDB account that has the same user name:

```
CREATE USER wlad IDENTIFIED VIA named_pipe;
CREATE USER monty IDENTIFIED VIA named_pipe;
quit

C:\>echo %USERNAME%
wlad

C:\> mysql --user=wlad --protocol=PIPE
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 4
Server version: 10.1.12-MariaDB-debug Source distribution

Copyright (c) 2000, 2015, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]> quit
Bye

C:\> mysql --user=monty  --protocol=PIPE
ERROR 1698 (28000): Access denied for user 'monty'@'localhost'
```

`PARSEC`

The PARSEC (Password Authentication using Response Signed with Elliptic Curve) authentication plugin uses salted passwords, key derivation, an extensible password storage format, and both server- and client-side scrambles. It signs the authentication response with stock unmodified `ed25519` (as provided by OpenSSL, WolfSSL, or GnuTLS). PARSEC is intended to become the default authentication plugin in a future release.

This plugin is available from MariaDB Community Server 11.6 and MariaDB Enterprise Server 11.8.

`caching_sha2_password`

The caching_sha2_password authentication plugin provides MySQL-compatible authentication and allows users to be moved from MySQL to MariaDB without changing their passwords. It is intended primarily as a migration aid; for new accounts the more secure PARSEC authentication plugin is recommended.

This plugin is available from MariaDB Community Server 12.1 and MariaDB Enterprise Server 11.8, and is not installed by default — see Authentication Plugin - caching_sha2_password for installation instructions.

Authentication Plugin - caching_sha2_password

> **Note:**
>
> This plugin is available from these MariaDB Server 11.4 versions: MariaDB Community Server 11.4.9 / 11.8.4, MariaDB Enterprise Server 11.4.10-7 / 11.8.6-3.

Overview

To aid migrations MariaDB provides MySQL compatible `caching_sha2_password` authentication plugin. It allows to move users from MySQL to MariaDB without requiring them to change their passwords. It should be only used for migration, otherwise a more secure and convenient PARSEC plugin is recommended.

Installing the Plugin

The `caching_sha2_password` authentication plugin's shared library is included in MariaDB packages as the `auth_mysql_sha2.so` or `auth_mysql_sha2.dll` shared library on systems where it can be built.

> **Warning:**
>
> Some builds also contain a file named `caching_sha2_password.so` or `caching_sha2_password.dll`. That one *cannot* be loaded by the server, though – it's the client plugin implementing the client side of this authentication protocol.

Although the plugin's shared library is distributed with MariaDB, the plugin is not actually installed into MariaDB by default. There are two methods that can be used to install the plugin into MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN:

```
INSTALL SONAME 'auth_mysql_sha2';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the –plugin-load or the –plugin-load-add options. This can be specified as a command-line argument to mariadbd or it can be specified in a relevant server option group in an option file:

```
[mariadb]
...
plugin_load_add = auth_mysql_sha2
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN:

```
UNINSTALL SONAME 'auth_mysql_sha2';
```

If you installed the plugin by providing the –plugin-load or the –plugin-load-add options in a relevant server option group in an option file, then those options must be removed to prevent the plugin from being loaded the next time the server is restarted.

Using the Plugin

To create a user in MariaDB that was using `caching_sha2_password` plugin in MySQL, issue this statement:

```
CREATE USER user@host IDENTIFIED WITH caching_sha2_password USING 'authentication_string';
```

Here, `authentication_string` is taken from the `mysql.user` table for the corresponding user in MySQL installation. Beware that the authentication string for `caching_sha2_password` in MySQL can contain non-printable

characters and copying it from the terminal window will likely not work.

System Variables

`caching_sha2_password_private_key_path`

- Description: A path to the private RSA key used for authentication.
- Command line: `--caching-sha2-password-private-key-path`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: `private_key.pem`
- Introduced: MariaDB 11.4.9, MariaDB 11.8.4

`caching_sha2_password_public_key_path`

- Description: A path to the public RSA key used for authentication.
- Command line: `--caching-sha2-password-public-key-path`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: `public_key.pem`
- Introduced: MariaDB 11.4.9, MariaDB 11.8.4

`caching_sha2_password_auto_generate_rsa_keys`

- Description: Auto generate RSA keys at server startup if key paths are not explicitly set and key files are not present at their default locations.
- Command line: `--caching-sha2-password-auto-generate-rsa-keys`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `ON`
- Introduced: MariaDB 11.4.9, MariaDB 11.8.4

`caching_sha2_password_digest_rounds`

- Description: Number of SHA2 rounds to be performed when computing a password hash.
- Command line: `--caching-sha2-password-digest-rounds`
- Scope: Global
- Dynamic: No
- Data Type: `integer`
- Default Value: `5000`
- Introduced: MariaDB 11.4.9, MariaDB 11.8.4

This page is licensed: CC BY-SA / Gnu FDL

Authentication Plugin - ed25519

MySQL has used SHA-1 based authentication since version 4.1. The authentication plugin is called mysql_native_password. Over the years as computers became faster, new attacks on SHA-1 were being developed.

Nowadays SHA-1 is no longer considered as secure as it was in 2001. That's why the `ed25519` authentication plugin was created.

The `ed25519` authentication plugin uses Elliptic Curve Digital Signature Algorithm (ECDSA) to securely store users' passwords and to authenticate users. The ed25519 algorithm is the same one that is used by OpenSSH. It is based on the elliptic curve and code created by Daniel J. Bernstein.

Installing the Plugin

Although the plugin's shared library is distributed by default with MariaDB, with a file name of `auth_ed25519.so` (Unix) or `auth_ed25519.dll` (Windows), the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN:

```
INSTALL SONAME 'auth_ed25519';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the –plugin-load or the –plugin-load-add options. This can be specified as a command-line argument to mariadbd or it can be specified in a relevant server option group in an option file:

```
[mariadb]
...
plugin_load_add = auth_ed25519
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN:

```
UNINSTALL SONAME 'auth_ed25519';
```

If you installed the plugin by providing the –plugin-load or the –plugin-load-add options in a relevant server option group in an option file, those options must be removed to prevent the plugin from being loaded the next time the server is restarted.

Creating Users

You can create a user account by executing the CREATE USER statement and providing the IDENTIFIED VIA clause followied by the name of the plugin, `ed25519`, and providing the `USING` clause followed by the PASSWORD() function, with the plain-text password as an argument:

```
CREATE USER username@hostname IDENTIFIED VIA ed25519 USING PASSWORD('secret');
```

If SQL_MODE does not have `NO_AUTO_CREATE_USER` set, then you can also create the user account via GRANT:

```
GRANT SELECT ON db.* TO username@hostname IDENTIFIED VIA ed25519 USING PASSWORD('secret');
```

The PASSWORD() function and SET PASSWORD statements don't work with the `ed25519` authentication plugin. Instead, you have to use the UDF that comes with the authentication plugin to calculate the password hash:

```
CREATE FUNCTION ed25519_password RETURNS STRING SONAME "auth_ed25519.so";
```

Now you can calculate a password hash by executing this query:

```
SELECT ed25519_password("secret");
+--------------------------------------------+
| SELECT ed25519_password("secret");         |
+--------------------------------------------+
| ZIgUREUg5PVgQ6LskhXmO+eZLS0nC8be6HPjYWR4YJY |
+--------------------------------------------+
```

Now you can use it to create the user account using the new password hash. As with any password, you should always use a complex password that isn't easy to guess. If you don't, if anyone gets access to the stored passwords in the `mysql.user` table, they could use rainbow tables to figure out the original password.

To create a user account via CREATE USER, specify the name of the plugin in the IDENTIFIED VIA clause while providing the password hash as the `USING` clause:

```
CREATE USER username@hostname IDENTIFIED VIA ed25519
  USING 'ZIgUREUg5PVgQ6LskhXmO+eZLS0nC8be6HPjYWR4YJY';
```

If SQL_MODE does not have `NO_AUTO_CREATE_USER` set, you can also create the user account via GRANT:

```
GRANT SELECT ON db.* TO username@hostname IDENTIFIED VIA ed25519
  USING 'ZIgUREUg5PVgQ6LskhXmO+eZLS0nC8be6HPjYWR4YJY';
```

Warning:

Note that users require a password in order to be able to connect. It is possible to create users without specifying a password, but they will be unable to connect.

Changing User Passwords

You can change a user account's password by executing the SET PASSWORD statement followed by the PASSWORD() function and providing the plain-text password as an argument:

```
SET PASSWORD =  PASSWORD('new_secret')
```

You can also change the user account's password with the ALTER USER statement. You would have to specify the name of the plugin in the IDENTIFIED VIA clause while providing the plain-text password as an argument to the `PASSWORD()` function in the `USING` clause:

```
ALTER USER username@hostname IDENTIFIED VIA ed25519 USING PASSWORD('new_secret');
```

The `PASSWORD()` function and SET PASSWORD statement did not work with the `ed25519` authentication plugin. Instead, you would have to use the UDF that comes with the authentication plugin to calculate the password hash:

```
CREATE FUNCTION ed25519_password RETURNS STRING SONAME "auth_ed25519.so";
```

Now you can calculate a password hash by executing this query:

```
SELECT ed25519_password("secret");
+--------------------------------------------+
| SELECT ed25519_password("secret");         |
+--------------------------------------------+
| ZIgUREUg5PVgQ6LskhXmO+eZLS0nC8be6HPjYWR4YJY |
+--------------------------------------------+
```

Now you can change the user account's password using the new password hash.

You can change the user account's password with the ALTER USER statement. You have to specify the name of the plugin in the IDENTIFIED VIA clause, while providing the password hash as the `USING` clause:

```
ALTER USER username@hostname IDENTIFIED VIA ed25519
  USING 'ZIgUREUg5PVgQ6LskhXmO+eZLS0nC8be6HPjYWR4YJY';
```

Client Authentication Plugins

For clients that use the `libmysqlclient` or MariaDB Connector/C libraries, MariaDB provides one client authentication plugin that is compatible with the `ed25519` authentication plugin:

- `client_ed25519`

When connecting with a client or utility to a server as a user account that authenticates with the `ed25519` authentication plugin, you may need to tell the client where to find the relevant client authentication plugin by specifying the `--plugin-dir` option:

```
mysql --plugin-dir=/usr/local/mysql/lib64/mysql/plugin --user=alice
```

`client_ed25519`

The `client_ed25519` client authentication plugin hashes and signs the password using the Elliptic Curve Digital Signature Algorithm (ECDSA) before sending it to the server.

Support in Client Libraries

Using the Plugin with MariaDB Connector/C

MariaDB Connector/C supports `ed25519` authentication using the client authentication plugins mentioned in the previous section.

Using the Plugin with MariaDB Connector/ODBC

MariaDB Connector/ODBC supports `ed25519` authentication using the client authentication plugins mentioned in the previous section.

Using the Plugin with MariaDB Connector/J

MariaDB Connector/J supports `ed25519` authentication.

Using the Plugin with MariaDB Connector/Node.js

MariaDB Connector/Node.js supports `ed25519` authentication.

Using the Plugin with MySqlConnector for .NET

MySqlConnector for ADO.NET supports `ed25519` authentication.

The connector implemented support for this authentication plugin in a separate NuGet package called MySqlConnector.Authentication.Ed25519. After the package is installed, your application must call `Ed25519AuthenticationPlugin.Install` to enable it.

Options

`ed25519`

- Description: Controls how the server should treat the plugin when it starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.

        - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
        - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
    - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- Command line: `--ed25519=value`
- Data Type: `enumerated`
- Default Value: `ON`
- Valid Values: `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

Authentication Plugin - GSSAPI

The `gssapi` authentication plugin allows the user to authenticate with services that use the Generic Security Services Application Program Interface (GSSAPI). Windows has a slightly different but very similar API called Security Support Provider Interface (SSPI). The GSSAPI is a standardized API described in RFC2743 and RFC2744. The client and server negotiate using a standardized protocol described in RFC7546.

On Windows, this authentication plugin supports Kerberos and NTLM authentication. Windows authentication is supported regardless of whether a domain is used in the environment.

On Unix systems, the most dominant GSSAPI service is Kerberos. However, it is less commonly used on Unix systems than it is on Windows. Regardless, this authentication plugin also supports Kerberos authentication on Unix.

The `gssapi` authentication plugin is most often used for authenticating with Microsoft Active Directory.

This article gives instructions on configuring the `gssapi` authentication plugin for MariaDB for passwordless login.

Installing the Plugin's Package

> **Note:**
>
> Before MariaDB 10.11, the GSSAPI server plugin was distributed on Windows as a dynamic plugin (`auth_gssapi.dll`). Since MariaDB 10.11, the plugin is statically compiled into the server and enabled by default. As a result, `auth_gssapi.dll` is no longer produced or required.

The `gssapi` authentication plugin's shared library is included in MariaDB packages as the `auth_gssapi.so` or `auth_gssapi.dll` shared library on systems where it can be built.

Installing on Linux

The `gssapi` authentication plugin is included in binary tarballs on Linux.

Installing with a Package Manager

The `gssapi` authentication plugin can also be installed via a package manager on Linux. In order to do so, your system needs to be configured to install from one of the MariaDB repositories.

You can configure your package manager to install it from MariaDB Corporation's MariaDB Package Repository by using the MariaDB Package Repository setup script.

You can also configure your package manager to install it from MariaDB Foundation's MariaDB Repository by using the MariaDB Repository Configuration Tool.

Installing with yum/dnf

On RHEL, CentOS, Fedora, and other similar Linux distributions, it is highly recommended to install the relevant RPM package from MariaDB's repository using yum or dnf. Starting with RHEL 8 and Fedora 22, `yum` has been replaced by `dnf`, which is the next major version of `yum`. However, `yum` commands still work on many systems that use `dnf`:

```
sudo yum install MariaDB-gssapi-server
```

Installing with apt-get

On Debian, Ubuntu, and other similar Linux distributions, it is highly recommended to install the relevant DEB package from MariaDB's repository using apt-get:

```
sudo apt-get install mariadb-plugin-gssapi-server
```

Installing with zypper

On SLES, OpenSUSE, and other similar Linux distributions, it is highly recommended to install the relevant RPM package from MariaDB's repository using zypper:

```
sudo zypper install MariaDB-gssapi-server
```

Installing on Windows

> **Note:**
>
> Before MariaDB 10.11, the `gssapi` authentication plugin is included in MSI and ZIP packages on Windows.

Installing the Plugin

> **Note:**
>
> Since MariaDB 10.11, on Windows, the GSSAPI server plugin is statically compiled into the server and enabled by default. No separate installation is required.

On Windows, and on other operating systems, although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN:

```
INSTALL SONAME 'auth_gssapi';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the –plugin-load or the –plugin-load-add options. This can be specified as a command-line argument to mariadbd or it can be specified in a relevant server option group in an option file:

```
[mariadb]
...
plugin_load_add = auth_gssapi
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN:

```
UNINSTALL SONAME 'auth_gssapi';
```

If you installed the plugin by providing the –plugin-load or the –plugin-load-add options in a relevant server option group in an option file, then those options must be removed to prevent the plugin from being loaded the next time the server is restarted.

Configuring the Plugin

If the MariaDB server is running on Unix, then some additional configuration steps will need to be implemented in order to use the plugin.

If the MariaDB server is running on Windows, then no special configuration steps will need to be implemented in order to use the plugin, as long as the following is true:

- The Windows server is joined to a domain.
- The MariaDB server process is running as either a NetworkService Account or a Domain User Account.

Creating a Keytab File on Unix

If the MariaDB server is running on Unix, then the KDC server will need to create a keytab file for the MariaDB server. The keytab file contains the service principal name, which is the identity that the MariaDB server will use to communicate with the KDC server. The keytab will need to be transferred to the MariaDB server, and the `mysqld` server process will need read access to this keytab file.

How this keytab file is generated depends on whether the KDC server is Microsoft Active Directory KDC or MIT Kerberos KDC.

Creating a Keytab File with Microsoft Active Directory

If you are using Microsoft Active Directory KDC, you may need to create a keytab using the ktpass.exe utility on a Windows host. The service principal will need to be mapped to an existing domain user. To do so, follow the steps listed below.

Be sure to replace the following items in the step below:

- Replace `${HOST}` with the fully qualified DNS name for the MariaDB server host.
- Replace `${DOMAIN}` with the Active Directory domain.
- Replace `${AD_USER}` with the existing domain user.
- Replace `${PASSWORD}` with the password for the service principal.

To create the service principal, execute the following command:

```
ktpass.exe /princ mariadb/${HOST}@${DOMAIN} /mapuser ${AD_USER} /pass ${PASSWORD} /out mariadb.keytab
/crypto all /ptype KRB5_NT_PRINCIPAL /mapop set
```

Creating a Keytab File with MIT Kerberos

If you are using MIT Kerberos KDC, then you can create a keytab file using the kadmin utility. To do so, follow the steps listed below.

In the following steps, be sure to replace `${HOST}` with the fully qualified DNS name for the MariaDB server host.

First, create the service principal using the kadmin utility:

```
kadmin -q "addprinc -randkey mariadb/${HOST}"
```

Then, export the newly created user to the keytab file using the kadmin utility:

```
kadmin -q "ktadd -k /path/to/mariadb.keytab mariadb/${HOST}"
```

More details can be found at the following links:

- MIT Kerberos Documentation: Database administration
- MIT Kerberos Documentation: Application servers

Configuring the Path to the Keytab File on Unix

If the MariaDB server is running on Unix, then the path to the keytab file that was previously created can be set by configuring the gssapi_keytab_path system variable. This can be specified as a command-line argument to mariadbd, or it can be specified in a relevant server option group in an option file:

```
[mariadb]
...
gssapi_keytab_path=/path/to/mariadb.keytab
```

Configuring the Service Principal Name

The service principal name can be set by configuring the gssapi_principal_name system variable. This can be specified as a command-line argument to mariadbd, or it can be specified in a relevant server option group in an option file:

```
[mariadb]
...
gssapi_principal_name=service_principal_name/host.domain.com@REALM
```

If a service principal name is not provided, the plugin tries to use `mariadb/host.domain.com@REALM` by default.

If the MariaDB server is running on Unix, the plugin needs a service principal name in order to function.

If the MariaDB server is running on Windows, the plugin does not usually need a service principal in order to function. However, if you want to use one, anyway, it can be created with the `setspn` utility.

Different KDC implementations may use different canonical forms to identify principals. See RFC2744: Section 3.10 to learn what the standard says about principal names.

More details can be found at the following links:

- Active Directory Domain Services: Service Principal Names
- MIT Kerberos Documentation: Realm configuration decisions
- MIT Kerberos Documentation: Principal names and DNS

Creating Users

To create a user account via CREATE USER, specify the name of the plugin in the IDENTIFIED VIA clause:

```
CREATE USER username@hostname IDENTIFIED VIA gssapi;
```

If SQL_MODE does not have `NO_AUTO_CREATE_USER` set, then you can also create the user account via GRANT:

```
GRANT SELECT ON db.* TO username@hostname IDENTIFIED VIA gssapi;
```

You can also specify the user's realm for MariaDB with the `USING` clause:

```
CREATE USER username@hostname IDENTIFIED VIA gssapi USING 'username@EXAMPLE.COM';
```

The format of the realm depends on the specific authentication mechanism that is used. For example, the format would need to be `machine\\username` for Windows users authenticating with NTLM.

If the realm is not provided in the user account's definition, then the realm is **not** used for comparison. Therefore, 'usr1@EXAMPLE.COM', 'usr1@EXAMPLE.CO.UK' and 'mymachine\usr1' would all identify as the following user account:

```
CREATE USER usr1@hostname IDENTIFIED VIA gssapi;
```

Creating Users Identified Via Group Membership or SID (Windows-specific)

On Windows only, it is possible to login using a AD or local group-membership. This is achieved by using the `GROUP` prefix in `IDENTIFIED ... AS`:

```
CREATE USER root IDENTIFIED VIA gssapi AS 'GROUP:Administrators'
CREATE USER root IDENTIFIED VIA gssapi AS 'GROUP:BUILTIN\\Administrators'
```

The effect of the above definition is that every user that identifies as a member of group `Administrators` can log in using the user name `root` without a password.

User can also login using own or group SID (Security Identifier):

```
CREATE USER root IDENTIFIED VIA gssapi AS 'SID:S-1-5-32-544'
```

Using SIDs will perform slightly faster than using name (since it will spare translation between SID and name which is otherwise done). SIDs are immune against user or group renaming.

Passwordless login on Windows

> **Note:**
>
> This feature is available from MariaDB 10.11.

On Windows, in addition to the usual authentication with a password, passwordless authentication is permitted when creating the `root` user during installation. This works in a similar manner to Unix socket authentication. However, since auth_gssapi, unlike unix_socket, requires client support, to avoid failures when MariaDB is used with third-party drivers, authentication on Windows first attempts password-based `native_authentication`, and only if it fails, falls back to passwordless `auth_gssapi`.

Client Authentication Plugins

For clients that use the `libmysqlclient` or MariaDB Connector/C libraries, MariaDB provides one client authentication plugin that is compatible with the `gssapi` authentication plugin:

- `auth_gssapi_client`

When connecting with a client or utility to a server as a user account that authenticates with the `gssapi` authentication plugin, you may need to tell the client where to find the relevant client authentication plugin by specifying the `--plugin-dir` option:

```
mysql --plugin-dir=/usr/local/mysql/lib64/mysql/plugin --user=alice
```

`auth_gssapi_client`

The `auth_gssapi_client` client authentication plugin receives the principal name from the server, and then uses either the gss_init_sec_context function (on Unix) or the InitializeSecurityContext function (on Windows) to establish a security context on the client.

Support in Client Libraries

Using the Plugin with MariaDB Connector/C

MariaDB Connector/C supports `gssapi` authentication using the client authentication plugins mentioned in the previous section.

Using the Plugin with MariaDB Connector/ODBC

MariaDB Connector/ODBC supports `gssapi` authentication using the client authentication plugins mentioned in the previous section.

Using the Plugin with MariaDB Connector/J

MariaDB Connector/J supports `gssapi` authentication. Current documentation can be found here.

Using the Plugin with MariaDB Connector/Node.js

MariaDB Connector/Node.js does not yet support `gssapi` authentication. See CONJS-72 for more information.

Using the Plugin with MySqlConnector for .NET

MySqlConnector for ADO.NET supports `gssapi` authentication.

The support is transparent. Normally, the connector only needs to be provided the correct user name, and no other parameters are required.

However, this connector also supports the ServerSPN connection string parameter, which can be used for mutual authentication.

.NET specific problems/workarounds

When connecting from Unix client to Windows server with ADO.NET, in an Active Directory domain environment, be aware that .NET Core on Unix does not support principal names in UPN(User Principal Name) form, which is default on Windows (e.g machine$@domain.com) . Thus, upon encountering an authentication exception with “server not found in Kerberos database”, use one of workarounds below

- Force host-based SPN on server side.
  - For example, this can be done by setting the gssapi_principal_name system variable to `HOST/machine` in a server option group in an option file.
- Pass host-based SPN on client side.
  - For example, this can be done by setting the connector’s ServerSPN connection string parameter to `HOST/machine`.

System Variables

`gssapi_keytab_path`

- Description: Defines the path to the server’s keytab file.
  - This system variable is only meaningful on Unix.
  - See Creating a Keytab File on Unix and Configuring the Path to the Keytab File on Unix for more information.
- Command line: `--gssapi-keytab-path`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: ’’

- Introduced: MariaDB 10.1.11

`gssapi_principal_name`

- Description: Name of the service principal.
  - See Configuring the Service Principal Name for more information.
- Command line: `--gssapi-principal-name`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: ''
- Introduced: MariaDB 10.1.11

`gssapi_mech_name`

- Description: Name of the SSPI package used by server. Can be either 'Kerberos' or 'Negotiate'. Set it to 'Kerberos', to prevent less secure NTLM in domain environments, but leave it as default (Negotiate) to allow non-domain environments (e.g if server does not run in a domain environment).
  - This system variable is only meaningful on Windows.
- Command line: `--gssapi-mech-name`
- Scope: Global
- Dynamic: No
- Data Type: `enumerated`
- Default Value: `Negotiate`
- Valid Values: `Kerberos`, `Negotiate`
- Introduced: MariaDB 10.1.11

Options

`gssapi`

- Description: Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- Command line: `--gssapi=value`
- Data Type: `enumerated`
- Default Value: `ON`
- Valid Values: `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`
- Introduced: MariaDB 10.1.11

Authentication Plugin - mysql_native_password

The `mysql_native_password` authentication plugin is the default authentication plugin that will be used for an account created when no authentication plugin is explicitly mentioned and old_passwords=0 is set. It uses the password hashing algorithm introduced in MySQL 4.1, which is also used by the PASSWORD() function when old_passwords=0 is set. This hashing algorithm is based on SHA-1.

It is not recommended to use the `mysql_native_password` authentication plugin for new installations that require **high password security**. If someone is able to both listen to the connection protocol and get a copy of the mysql.user table, then the person would be able to use this information to connect to the MariaDB server. The ed25519 authentication plugin is a more modern authentication plugin that provides simple password authentication using a more secure algorithm.

Installing the Plugin

The `mysql_native_password` authentication plugin is statically linked into the server, so no installation is necessary.

Creating Users

The easiest way to create a user account with the `mysql_native_password` authentication plugin is to make sure that old_passwords=0 is set, and then create a user account via CREATE USER that does not specify an authentication plugin, but does specify a password via the IDENTIFIED BY clause:

```
SET old_passwords=0;
CREATE USER username@hostname IDENTIFIED BY 'mariadb';
```

If SQL_MODE does not have `NO_AUTO_CREATE_USER` set, then you can also create the user account via GRANT:

```
SET old_passwords=0;
GRANT SELECT ON db.* TO username@hostname IDENTIFIED BY 'mariadb';
```

You can also create the user account by providing a password hash via the IDENTIFIED BY PASSWORD clause, and MariaDB will validate whether the password hash is one that is compatible with `mysql_native_password`:

```
SET old_passwords=0;

SELECT PASSWORD('mariadb');
+-------------------------------------------+
| PASSWORD('mariadb')                       |
+-------------------------------------------+
| *54958E764CE10E50764C2EECBB71D01F08549980 |
+-------------------------------------------+

CREATE USER username@hostname
  IDENTIFIED BY PASSWORD '*54958E764CE10E50764C2EECBB71D01F08549980';
```

Similar to all other authentication plugins, you could also specify the name of the plugin in the IDENTIFIED VIA clause while providing the password hash as the `USING` clause:

```
CREATE USER username@hostname
  IDENTIFIED VIA mysql_native_password USING '*54958E764CE10E50764C2EECBB71D01F08549980';
```

Changing User Passwords

You can change a user account's password with the SET PASSWORD statement while providing the plain-text password as an argument to the PASSWORD() function:

```
SET PASSWORD =  PASSWORD('new_secret')
```

You can also change the user account's password with the ALTER USER statement. You would have to make sure that old_passwords=0 is set, and then you would have to specify a password via the IDENTIFIED BY clause:

```
SET old_passwords=0;
ALTER USER username@hostname IDENTIFIED BY 'new_secret';
```

Client Authentication Plugins

For clients that use the `libmysqlclient` or MariaDB Connector/C libraries, MariaDB provides one client authentication plugin that is compatible with the `mysql_native_password` authentication plugin:

- `mysql_native_password`

When connecting with a client or utility to a server as a user account that authenticates with the `mysql_native_password` authentication plugin, you may need to tell the client where to find the relevant client authentication plugin by specifying the `--plugin-dir` option:

```
mysql --plugin-dir=/usr/local/mysql/lib64/mysql/plugin --user=alice
```

However, the `mysql_native_password` client authentication plugin is generally statically linked into client libraries like `libmysqlclient` or MariaDB Connector/C, so this is not usually necessary.

`mysql_native_password`

The `mysql_native_password` client authentication plugin hashes the password before sending it to the server.

Support in Client Libraries

The `mysql_native_password` authentication plugin is one of the conventional authentication plugins, so all client libraries should support it.

Known Old Issues (Only Relevant for Old Installations)

Mismatches Between Password and authentication_string Columns

For compatibility reasons, the `mysql_native_password` authentication plugin tries to read the password hash from both the `Password` and `authentication_string` columns in the mysql.user table. This has caused issues in the past if one of the columns had a different value than the other.

> **CURRENT**
>
> CREATE USER, ALTER USER, GRANT, and SET PASSWORD set the `Password` and `authentication_string` columns in the mysql.user table whenever an account's password is changed.
>
> **< 10.3.11 / 10.2.19**
>
> CREATE USER, ALTER USER, GRANT, and SET PASSWORD do **not** set the `Password` and `authentication_string` columns in the mysql.user table whenever an account's password is changed.

See Also

- ed25519 secure connection plugin
- History of MySQL and MariaDB authentication protocols

This page is licensed: CC BY-SA / Gnu FDL

Authentication Plugin - mysql_old_password

The `mysql_old_password` authentication plugin is the default authentication plugin that is used for an account created when no authentication plugin is explicitly mentioned and old_passwords=1 is set. It uses the pre-MySQL 4.1 password hashing algorithm, which is also used by the OLD_PASSWORD() function and by the PASSWORD() function when `old_passwords=1` is set.

> **Important:**
>
> It is not recommended to use the `mysql_old_password` authentication plugin for new installations. The password hashing algorithm is no longer secure, and the plugin is primarily provided for backward compatibility. The ed25519 authentication plugin is a more modern authentication plugin that provides simple password authentication.

Installing the Plugin

The `mysql_old_password` authentication plugin is statically linked into the server, so no installation is necessary.

Creating Users

The easiest way to create a user account with the `mysql_old_password` authentication plugin is to make sure that old_passwords=1 is set, and create a user account via CREATE USER that does not specify an authentication plugin, but instead specifies a password via the IDENTIFIED BY clause:

```
SET old_passwords=1;
CREATE USER username@hostname IDENTIFIED BY 'mariadb';
```

If SQL_MODE does not have `NO_AUTO_CREATE_USER` set, then you can also create the user via GRANT:

```
SET old_passwords=1;
GRANT SELECT ON db.* TO username@hostname IDENTIFIED BY 'mariadb';
```

You can also create the user account by providing a password hash via the IDENTIFIED BY PASSWORD clause, and MariaDB validates whether the password hash is one that is compatible with `mysql_old_password`:

```
SET old_passwords=1;
Query OK, 0 rows affected (0.000 sec)

SELECT PASSWORD('mariadb');
+--------------------+
| PASSWORD('mariadb') |
+--------------------+
| 021bec665bf663f1    |
+--------------------+
1 row in set (0.000 sec)

CREATE USER username@hostname IDENTIFIED BY PASSWORD '021bec665bf663f1';
Query OK, 0 rows affected (0.000 sec)
```

Similar to all other authentication plugins, you could also specify the name of the plugin in the `IDENTIFIED VIA` clause, while providing the password hash as the `USING` clause:

```
CREATE USER username@hostname IDENTIFIED VIA mysql_old_password USING '021bec665bf663f1';
Query OK, 0 rows affected (0.000 sec)
```

Changing User Passwords

You can change a user account's password with the SET PASSWORD statement, while providing the plain-text password as an argument to the PASSWORD() function:

```
SET PASSWORD =  PASSWORD('new_secret')
```

You can also change the user account's password with the ALTER USER statement. You have to make sure that old_passwords=1 is set, and you have to specify a password via the IDENTIFIED BY clause:

```
SET old_passwords=1;
ALTER USER username@hostname IDENTIFIED BY 'new_secret';
```

Client Authentication Plugins

For clients that use the `libmysqlclient` or MariaDB Connector/C libraries, MariaDB provides one client authentication plugin that is compatible with the `mysql_old_password` authentication plugin:

- `mysql_old_password`

When connecting with a client or utility to a server as a user account that authenticates with the `mysql_old_password` authentication plugin. You may need to tell the client where to find the relevant client authentication plugin by specifying the `--plugin-dir` option:

```
mysql --plugin-dir=/usr/local/mysql/lib64/mysql/plugin --user=alice
```

However, the `mysql_old_password` client authentication plugin is generally statically linked into client libraries like `libmysqlclient` or MariaDB Connector/C, so this is not usually necessary.

`mysql_old_password`

The `mysql_old_password` client authentication plugin hashes the password before sending it to the server.

Support in Client Libraries

The `mysql_old_password` authentication plugin is one of the conventional authentication plugins, so all client libraries should support it.

This page is licensed: CC BY-SA / Gnu FDL

Authentication Plugin - Named Pipe

The `named_pipe` authentication plugin allows the user to use operating system credentials when connecting to MariaDB via named pipe on Windows. Named pipe connections are enabled by the named_pipe system variable.

The `named_pipe` authentication plugin works by using named pipe impersonation and calling `GetUserName()` to retrieve the user name of the process that is connected to the named pipe. Once it has the user name, it authenticates the connecting user as the MariaDB account that has the same user name.

Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN:

```
INSTALL SONAME 'auth_named_pipe';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the –plugin-load or the –plugin-load-add options. This can be specified as a command-line argument to mariadbd, or it can be specified in a relevant server option group in an option file:

```
[mariadb]
...
plugin_load_add = auth_named_pipe
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN:

```
UNINSTALL SONAME 'auth_named_pipe';
```

If you installed the plugin by providing the –plugin-load or the –plugin-load-add options in a relevant server option group in an option file, those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Creating Users

To create a user account via CREATE USER, specify the name of the plugin in the IDENTIFIED VIA clause:

```
CREATE USER username@hostname IDENTIFIED VIA named_pipe;
```

If SQL_MODE does not have `NO_AUTO_CREATE_USER` set, then you can also create the user account via GRANT:

```
GRANT SELECT ON db.* TO username@hostname IDENTIFIED VIA named_pipe;
```

Client Authentication Plugins

The `named_pipe` authentication plugin does not require any specific client authentication plugins. It should work with all clients.

Support in Client Libraries

The `named_pipe` authentication plugin does not require any special support in client libraries. It should work with all client libraries.

Example

```
CREATE USER wlad IDENTIFIED VIA named_pipe;
CREATE USER monty IDENTIFIED VIA named_pipe;
quit

C:\>echo %USERNAME%
wlad

C:\> mysql --user=wlad --protocol=PIPE
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 4
Server version: 10.1.12-MariaDB-debug Source distribution

Copyright (c) 2000, 2015, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]> quit
Bye

C:\> mysql --user=monty  --protocol=PIPE
ERROR 1698 (28000): Access denied for user 'monty'@'localhost'
```

In this example, a user `wlad` is already logged into the system. Because he has identified himself to the operating system, he does not need to do it again for the database — MariaDB trusts the operating system credentials.

However, he cannot connect to the database as another user.

Options

`named_pipe`

- Description: Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
  - There may be ambiguity between this option and the named_pipe system variable. See MDEV-19625 about that.
- Command line: `--named-pipe=value`
- Data Type: `enumerated`
- Default Value: `ON`
- Valid Values: `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`
- Introduced: MariaDB 10.1.11

This page is licensed: CC BY-SA / Gnu FDL

Authentication Plugin - PARSEC

> **Note:**
>
> This plugin is available from MariaDB 11.6.

The `PARSEC` Authentication Plugin is intended to be the default in a future release.

The `PARSEC` (Password Authentication using Response Signed with Elliptic Curve) authentication plugin uses salted passwords, key derivation, extensible password storage format, and both server- and client-side scrambles.

It signs the response with `ed25519`, but it uses stock unmodified `ed25519` as provided by OpenSSL/WolfSSL/GnuTLS.

Description

- The KDF function is pbkdf2 (supported by everything, including windows native, Java, javascript, PHP, .NET.
- Parameters to the pbkdf2 are stored in with authentication plugin data : hash function (SHA512,SHA256), iteration count, salt, key_length, together with derived key = `PBKDF2(func, password, salt, iteration_count, key_length).`
- The number of iterations is a power of two, at least 1024. From MariaDB 13.1, it is configurable through the `parsec_iterations` system variable.
- The algorithm is ed25519, “hash” is the public key generated using ed25519 from the PBKDF2(password).

The authentication string, stored by the server, is this:

```
concat('P', conv(log2(iterations)-10, 10, 62), ':', base64(salt), ':', base64(hash))
```

For example, it looks like this: `P0:WW9sXaaL/o:vubFBzIrapbfHct1/J72dnUryz5VS7lA6XHH8sIx4TI`

- It consists of colon-separated fields.
- The first field is 'P' (denotes KDF algorithm = PBKDF2) and the number of iterations, '0' means 1024, '1' means 2048, etc.
- This is followed by the salt.
- This is followed by the password hash.

The first two fields together are called *ext-salt*, extended salt.

Login Process, Packet Exchange

1. The server sends an Authentication Switch Request with a 32-byte random scramble.
2. The client sends an empty packet to the server to request the ext-salt.
3. The server sends the ext-salt to the client.
4. The client sends the random 32-byte scramble, and the `concat(server scramble, client scramble)` ed25519-signed by a secret key generated from the function `PBKDF2(password, ext-salt)`.
5. The server replies with "ok" or "access denied".

Installing

If you run into the error `ERROR 1524 (HY000): Plugin 'parsec' is not loaded` it means you need to install the authentication plugin first. You can do it on a running server with:

```
INSTALL SONAME 'auth_parsec';
```

There is no need to pass additional command-line options or have config files to keep the PARSEC authentication method available. Running the `INSTALL SONAME` once is enough and the MariaDB Server will remember it even if server is restarted or upgraded.

Example

```
CREATE USER test1@'%' IDENTIFIED VIA parsec USING PASSWORD('pwd');
```

Configuring the Number of Iterations

> **Note:**
>
> The `parsec_iterations` system variable is available from MariaDB 13.1.

The number of PBKDF2 iterations used to derive the key from a password is controlled by the `parsec_iterations` system variable. A higher value increases the cost of deriving the key, which strengthens resistance to brute-force attacks at the expense of more work per authentication.

The iteration count is baked into an account's stored credentials when its password is set. The value in effect at that time — the session value if set, otherwise the global value — is the one recorded for the account. Changing `parsec_iterations` afterwards does not alter existing accounts; they keep the iteration count they were created with until their password is set again.

```
SET SESSION parsec_iterations = 262144;
CREATE USER test1@'%' IDENTIFIED VIA parsec USING PASSWORD('pwd');
```

The value must be a power of two. If a value that is not a power of two is supplied, it is rounded up to the next power of two and a warning is issued:

```
SET GLOBAL parsec_iterations = 5000;
```

```
Warning (1231): parsec_iterations rounded up to 8192
```

`parsec_iterations`

- Description: Number of iterations used when generating the key corresponding to the password (PBKDF2-HMAC-SHA512). Rounded up to a power of two. This variable is only available when the PARSEC plugin is loaded.
- Commandline: `--parsec-iterations=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `INT UNSIGNED`
- Default Value: `1024`
- Minimum Value: `1024`
- Maximum Value: `1073741824`
- Introduced: MariaDB 13.1

Future

PARSEC is currently available in latest MariaDB versions, but not installed or used by default yet. Once MDEV-12320 is implemented, MariaDB plans to start using PARSEC as the default password authentication method.

Authentication Plugin - SHA-256

Background

MySQL 5.6 added support for the sha256_password authentication plugin, and MySQL 8.0 also added support for the caching_sha2_password authentication plugin.

The `caching_sha2_password` plugin is now the default authentication plugin in MySQL 8.0.4 and above, based on the value of the default_authentication_plugin system variable.

Support in MariaDB Server

> **Warning:**
>
> MariaDB **Server** does not support the sha256_password plugin. A `caching_sha2_password` authentication plugin was added in MariaDB Community Server 12.1 and Enterprise Server 11.8. See MDEV-9804 for more information.

Reasons for not supporting the SHA-256 plugin:

- To use the protocol, you have to distribute the server's public key to all MariaDB users, which can be cumbersome and impractical.
- The server receives the password in clear text, which can cause problems if the user connects to a malicious server.

If you are migrating from a MySQL instance that is using SHA-256 authentication, you have to change the SHA-256 authentication to `mysql_native_authentication` :

```
ALTER USER user_name IDENTIFIED WITH mysql_native_password BY 'new_password'
```

Support in Client Libraries

Client Authentication Plugins

For clients that use the MariaDB Connector/C library, MariaDB provides client authentication plugins that are compatible with MySQL's SHA-256 authentication plugins:

- `sha256_password`
- `caching_sha256_password`

When connecting with a client or utility to a server, using a user account that authenticates with the `sha256_password` or `caching_sha256_password` authentication plugin, you may need to tell the client where to find the relevant client authentication plugin by specifying the `--plugin-dir` option:

```
mysql --plugin-dir=/usr/local/mysql/lib64/mysql/plugin --user=alice
```

> **Warning:**
>
> For clients that use MariaDB's `libmysqlclient` library instead of MariaDB Connector/C, those authentication plugins are not supported.

`sha256_password`

The `sha256_password` client authentication plugin is compatible with MySQL's sha256_password authentication plugin, which was added in MySQL 5.6.

`caching_sha256_password`

The `caching_sha256_password` client authentication plugin is compatible with MySQL's caching_sha2_password authentication plugin, which was added in MySQL 8.0.

The `caching_sha2_password` plugin is now the default authentication plugin in MySQL 8.0.4 and above, based on the value of the default_authentication_plugin system variable.

Using the Plugin with MariaDB Connector/C

MariaDB Connector/C supports `sha256_password` and `caching_sha2_password` authentication using the client authentication plugins mentioned in the previous section.

It has supported the `sha256_password` client authentication plugin since MariaDB Connector/C 3.0.2. See CONC-229 for more information.

It has supported the `caching_sha256_password` client authentication plugin since MariaDB Connector/C 3.0.8 and MariaDB Connector/C 3.1.0. See CONC-312 for more information.

Using Plugins with MariaDB Connector/ODBC

MariaDB Connector/ODBC supports `sha256_password` and `caching_sha2_password` authentication using the client authentication plugins mentioned in the previous section.

It has supported `sha256_password` and `caching_sha2_password` authentication since MariaDB Connector/ODBC 3.1.4. See ODBC-241 for more information.

Using Plugins with MariaDB Connector/J

MariaDB Connector/J supports `sha256_password` and `caching_sha2_password` authentication since MariaDB Connector/J 2.5.0. See CONJ-327 and CONJ-663 for more information.

note: The version 3.x being a rewrite of the connector, only caching_sha2_password is implemented, since sha256_password is only implemented on EOL version.

Using Plugins with MariaDB Connector/Node.js

MariaDB Connector/Node.js supports `sha256_password` and `caching_sha2_password` authentication since MariaDB Connector/Node.js 2.5.0. See CONJS-76 and CONJS-77 for more information.

Authentication Plugin - Unix Socket

The `unix_socket` authentication plugin is installed by default, and it is used by the `'root'@'localhost'` user account by default. See Authentication for more information.

The `unix_socket` authentication plugin allows the user to use operating system credentials when connecting to MariaDB via the local Unix socket file. This Unix socket file is defined by the socket system variable.

The `unix_socket` authentication plugin works by calling the getsockopt system call with the `SO_PEERCRED` socket option, which allows it to retrieve the `uid` of the process that is connected to the socket. It is then able to get the user name associated with that `uid`. Once it has the user name, it will authenticate the connecting user as the MariaDB account that has the same user name.

The `unix_socket` authentication plugin is not suited to multiple Unix users accessing a single MariaDB user account.

Security

A `unix_socket` authentication plugin is a passwordless security mechanism. Its security lies in the strength of the access to the Unix user, rather than the complexity and the secrecy of the password.

> **Warning:**
>
> As security differs from password security, the strengths and weaknesses need to be considered, and those can differ depending on the specific installation.

Strengths

- Access is limited to the Unix user so, for example, a `www-data` user cannot access `root` with the `unix_socket` authentication plugin.
- There is no password which can be cracked by brute force.
- There is no password that can be accidentally exposed by user accident, poor security on backups, or poor security on passwords in configuration files.
- Default Unix user security is usually strong on preventing remote access and password brute force attempts.

Weaknesses

The strength of a `unix_socket` authentication plugin is effectively the strength of the security of the Unix users on the system. In most cases, the Unix user default installation is sufficiently secure. However, the following is a non-exhaustive list of potential Unix user security issues that may arise.

- Common access areas without screen locks, where an unauthorized user accesses the logged in Unix user of an authorized user.
- Extensive sudo access grants that provide users with access to execute commands of a different Unix user.
- Scripts writable by Unix users other than the Unix user that are executed (via cron or directly) by the Unix user.
- Web pages that are susceptible to command injection, where the Unix user running the web page has elevated privileges in the database that weren't intended to be used.
- Poor Unix user password practices including weak user passwords, password exposure and password reuse accompanied by an access vulnerability/mechanism of an unauthorized user to exploit this weakness.
- Weak remote access mechanisms and network file system privileges.
- Poor user security behavior including running untrusted scripts and software.

In some of these scenarios a database password may prevent these security exploits, however it will remove all the strengths of the `unix_socket` authentication plugin previously mentioned.

Disabling the Plugin

The `unix_socket` authentication plugin is installed by default.

> **Warning:**
>
> If you do not want it to be available by default, you must disable it.

The `unix_socket` authentication plugin is also installed by default in new installations that use the .deb packages provided by Debian's default repositories and Ubuntu's default repositories. See Differences in MariaDB in Debian (and Ubuntu) for more information.

The `unix_socket` authentication plugin can be disabled by starting the server with the unix_socket option set to `OFF`. This can be specified as a command-line argument to mysqld or it can be specified in a relevant server option group in an option file:

```
[mariadb]
...
unix_socket=OFF
```

As an alternative, the unix_socket option can also be set to `OFF` by pairing the option with the `disable` option prefix:

```
[mariadb]
...
disable_unix_socket
```

Installing the Plugin

The `unix_socket` authentication plugin is installed by default in almost all MariaDB server versions. If you work with a version that doesn't have the plugin installed, you can install it as described in one of the following ways.

- Install the plugin without restarting the server. You can install the plugin dynamically, by executing INSTALL SONAME or INSTALL PLUGIN:

```
INSTALL SONAME 'auth_socket';
```

- Instruct the server to load the plugin at startup. The plugin can be installed this way by providing the –plugin-load or the –plugin-load-add options. This can be specified as a command-line argument to mysqld or it can be specified in a relevant server option group in an option file:

```
[mariadb]
...
plugin_load_add = auth_socket
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN:

```
UNINSTALL SONAME 'auth_socket';
```

If you installed the plugin by providing the –plugin-load or the –plugin-load-add options in a server option group in an option file, those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Creating Users

To create a user account via CREATE USER, specify the name of the plugin in the IDENTIFIED VIA clause:

```
CREATE USER username@hostname IDENTIFIED VIA unix_socket;
```

If SQL_MODE does not have `NO_AUTO_CREATE_USER` set, then you can also create the user account via GRANT:

```
GRANT SELECT ON db.* TO username@hostname IDENTIFIED VIA unix_socket;
```

CURRENT

The authentication string (if present) is compared with the socket's user name. Authentication proceeds if there's a match. In this case, the external_user system variable contains the OS user.

Consider an OS user named 'bob' that has been created like this:

```
CREATE USER A identified via unix_socket as 'bob';
```

That user can connect like this:

```
mariadb -uA
```

Alternatively, accessing the sock file directly, the user can connect like this:

```
mariadb -uA -S /var/run/mysqld/mysqld.sock
```

Once connected, you can view that user like this:

```
SELECT USER(),@@external_user;
+-------------+-----------------+
| user()      | @@external_user |
+-------------+-----------------+
| A@localhost | bob             |
+-------------+-----------------+
```

< 11.6

The plugin only checks whether the OS socket user id matches the MariaDB user name. It ignores the authentication string.

Switching to Password-Based Authentication

If Unix socket authentication does not meet your needs, you can switch a user account back to password-based authentication, by telling MariaDB to use a different authentication plugin for the account. The specific authentication plugin is specified with the IDENTIFIED VIA clause. To switch to the mysql_native_password authentication plugin, you need to do this:

```
ALTER USER root@localhost IDENTIFIED VIA mysql_native_password;
SET PASSWORD = PASSWORD('foo');
```

Warning:

If you use scripts that require passwordless access to MariaDB, this would cause them to break. You may be able to fix that by setting a password in the `[client]` option group in your /root/.my.cnf option file.

```
[client]
password=foo
```

Client Authentication Plugins

The `unix_socket` authentication plugin does not require any specific client authentication plugins. It should work with all clients.

Support in Client Libraries

The `unix_socket` authentication plugin does not require any special support in client libraries. It should work with all client libraries.

Example

```
$ mysql -uroot
MariaDB []> CREATE USER serg IDENTIFIED VIA unix_socket;
MariaDB []> CREATE USER monty IDENTIFIED VIA unix_socket;
MariaDB []> quit
Bye
$ whoami
serg
$ mysql --user=serg
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 2
Server version: 5.2.0-MariaDB-alpha-debug Source distribution
MariaDB []> quit
Bye
$ mysql --user=monty
ERROR 1045 (28000): Access denied for user 'monty'@'localhost' (using password: NO)
```

In this example, user `serg` is already logged into the operating system and has full shell access. The user has already authenticated with the operating system and the MariaDB account is configured to use the `unix_socket` authentication plugin, so there is no need to authenticate again for the database. MariaDB accepts the operating system credentials and allows the user to connect. However, any attempt to connect to the database as another operating system is denied.

Options

`unix_socket`

- Description: Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugin table.

    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- Command line: `--unix-socket=value`
- Data Type: `enumerated`
- Default Value: `ON`
- Valid Values: `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

Authentication with Pluggable Authentication Modules (PAM)

See Authentication Plugin - PAM.

The PAM authentication plugin delegates password validation to the operating system's PAM framework, enabling integration with LDAP, Kerberos, and other services.

See Configuring PAM Authentication and User Mapping with LDAP Authentication.

Learn to configure the PAM plugin to authenticate users via LDAP and map LDAP groups to MariaDB accounts using the pam_user_map module.

See Configuring PAM Authentication and User Mapping with Unix Authentication.

This guide shows how to authenticate database users using local Unix accounts and map Unix groups to MariaDB users with the PAM plugin.

See User and Group Mapping with PAM.

The pam_user_map PAM module allows administrators to map external PAM users and groups to specific MariaDB accounts for flexible authorization management.

Authentication Plugin - PAM

Overview

The `pam` authentication plugin allows MariaDB to offload user authentication to the system's Pluggable Authentication Module (PAM) framework. PAM is an authentication framework used by Linux, FreeBSD, Solaris, and other Unix-like operating systems.

Note: Windows does not support PAM, so the `pam` authentication plugin does not support Windows. However, one can use a MariaDB client on Windows to connect to MariaDB server that is installed on a Unix-like operating system and that is configured to use the `pam` authentication plugin. For an example of how to do this, see the blog post: MariaDB: Improve Security with Two-Step Verification.

Use Cases

PAM makes it possible to implement various authentication scenarios of different complexity:

- Authentication using passwords from `/etc/shadow` (this is what a default PAM configuration usually does). See the pam_unix PAM module.
- Authentication using LDAP. See the pam_ldap PAM module.
- Authentication using Microsoft's Active Directory. See the pam_lsass, pam_winbind, and pam_centrifydc PAM modules.
- Authentication using one-time passwords (even with SMS confirmation!). See the pam_google_authenticator and pam_securid PAM modules.
- Authentication using SSH keys. See the pam_ssh PAM module.
- User and group mapping. See the pam_user_map PAM module.
- Combining different authentication modules in interesting ways in a PAM service.
- Password expiration.
- Limiting access by time, date, day of the week, etc. See the pam_time PAM module.
- Logging of every login attempt.

Installing the Plugin

The `pam` authentication plugin's library is provided in binary packages in all releases on Linux.

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN:

```
INSTALL SONAME 'auth_pam';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the –plugin-load or the –plugin-load-add options. This can be specified as a command-line argument to mysqld or it can be specified in a relevant server option group in an option file:

```
[mariadb]
...
plugin_load_add = auth_pam
```

Installing the v1 Plugin

The `auth_pam` shared library actually refers to version `2.0` of the `pam` authentication plugin. Version `1.0` of the plugin as the `auth_pam_v1` shared library is also available.

If you need to install version `1.0` of the authentication plugin instead of version `2.0`, install it with INSTALL SONAME or INSTALL PLUGIN:

```
INSTALL SONAME 'auth_pam_v1';
```

Alternatively, specify it in a relevant server option group in an option file:

```
[mariadb]
...
plugin_load_add = auth_pam_v1
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN:

```
UNINSTALL SONAME 'auth_pam';
```

If you installed the plugin by providing the –plugin-load or the –plugin-load-add options in a relevant server option group in an option file, those options must be removed to prevent the plugin from being loaded the next time the server is restarted.

Uninstalling the v1 Plugin

If you installed version `1.0` of the authentication plugin, you can uninstall it by executing a similar statement for `auth_pam_v1`:

```
UNINSTALL SONAME 'auth_pam_v1';
```

Configuring PAM

The `pam` authentication plugin tells MariaDB to delegate the authentication to the PAM authentication framework. How exactly that authentication is performed depends on how PAM is configured.

Configuring the PAM Service

PAM is divided into `services`. PAM services are configured by PAM configuration files. Typically, the global PAM configuration file is located at `/etc/pam.conf` and PAM directory-based configuration files for individual services are located in `/etc/pam.d/`.

If you want to use a PAM service called `mariadb` for your MariaDB PAM authentication, then the PAM configuration file for that service would also be called `mariadb`, and it would typically be located at `/etc/pam.d/mariadb`.

For example, here is a minimal PAM service configuration file that performs simple password authentication with UNIX passwords:

```
auth required pam_unix.so audit
account required pam_unix.so audit
```

Let's breakdown this relatively simple PAM service configuration file.

Each line of a PAM service configuration file has the following general format:

```
type control module-path module-arguments
```

It instructs the PAM authentication framework that for successful **authentication** (i.e. type=auth), it is **required** that the `pam_unix.so` PAM module returns a success. It also instructs the PAM authentication framework that for an **account** (i.e. type=account) to be valid, it is **required** that the `pam_unix.so` PAM module returns a success.

PAM also supports session and password types, but MariaDB's `pam` authentication plugin does not support those.

The above PAM service configuration file also provides the `audit` module argument to the `pam_unix` PAM module. The pam_unix manual says that this module argument enables extreme debug logging to the syslog.

On most systems, you can find many other examples of PAM service configuration files in your `/etc/pam.d/` directory.

Configuring the pam_unix PAM Module

If you configure PAM to use the pam_unix PAM module (as in the above example), then you might notice on some systems that this will fail by default with errors like the following:

```
Apr 14 12:56:23 localhost unix_chkpwd[3332]: check pass; user unknown
Apr 14 12:56:23 localhost unix_chkpwd[3332]: password check failed for user (alice)
Apr 14 12:56:23 localhost mysqld: pam_unix(mysql:auth): authentication failure; logname= uid=991 euid=991
tty= ruser= rhost=  user=alice
```

The problem is that on some systems, the `pam_unix` PAM module needs access to `/etc/shadow` in order to function, and most systems only allow `root` to access that file by default.

Newer versions of PAM do not have this limitation, so you may want to try upgrading your version of PAM to see if that fixes the issue.

If that does not work, then you can work around this problem by giving the user that runs mysqld access to `/etc/shadow`. For example, if the `mysql` user runs mysqld, then you could do the following:

```
sudo groupadd shadow
sudo usermod -a -G shadow mysql
sudo chown root:shadow /etc/shadow
sudo chmod g+r /etc/shadow
```

After configuring, you have to restart the server. The server should now be able to read `/etc/shadow`.

The `pam` authentication plugin uses a setuid wrapper to perform its PAM checks, so it should not need any special workarounds to perform privileged operations, such as reading `/etc/shadow` when using the `pam_unix` PAM module. See MDEV-7032 for more information.

Creating Users

To create a user in MariaDB which uses the `pam` authentication plugin, execute CREATE USER while specifying the name of the plugin in the IDENTIFIED VIA clause:

```
CREATE USER username@hostname IDENTIFIED VIA pam;
```

If SQL_MODE does not have `NO_AUTO_CREATE_USER` set, then you can also create the user this way with GRANT:

```
GRANT SELECT ON db.* TO username@hostname IDENTIFIED VIA pam;
```

You can also specify a PAM service name for MariaDB to use by providing it with the `USING` clause:

```
CREATE USER username@hostname IDENTIFIED VIA pam USING 'mariadb';
```

This line creates a user that needs to be authenticated via the `pam` authentication plugin using the PAM service name `mariadb`. As mentioned in a previous section, this service's configuration file will typically be present in `/etc/pam.d/mariadb`.

If no service name is specified, then the plugin will use `mysql` as the default PAM service name.

Client Authentication Plugins

For clients that use the `libmysqlclient` or MariaDB Connector/C libraries, MariaDB provides two client authentication plugins that are compatible with the `pam` authentication plugin:

- `dialog`
- `mysql_clear_password`

When connecting with a client or utility to a server as a user account that authenticates with the `pam` authentication plugin, you may need to tell the client where to find the relevant client authentication plugin by specifying the `--plugin-dir` option:

```
mariadb --plugin-dir=/usr/local/mysql/lib64/mysql/plugin --user=alice
```

Both the `dialog` and the `mysql_clear_password` client authentication plugins transmit the password to the server in clear text. Therefore, when you use the `pam` authentication plugin, it is very important to encrypt client connections using TLS to prevent the clear-text passwords from being seen by unauthorized users.

`dialog`

Usually the `pam` authentication plugin uses the `dialog` client authentication plugin to communicate with the user. This client authentication plugin allows MariaDB to support arbitrarily complex PAM configurations with regular or one-time passwords, challenge-response, multiple questions, or just about anything else. When using a MariaDB client library, there is no need to install or enable anything — the `dialog` client authentication plugin is loaded by the client library completely automatically and transparently for the application.

The `dialog` client authentication plugin was developed by MariaDB, so MySQL's clients and client libraries as well as third party applications that bundle MySQL's client libraries do not support the `dialog` client authentication plugin out of the box. If the server tells an unsupported client to use the `dialog` client authentication plugin, then the client is likely to throw an error like the following:

```
ERROR 2059 (HY000): Authentication plugin 'dialog' cannot be loaded: /usr/lib/mysql/plugin/dialog.so:
cannot open shared object file: No such file or directory
```

For some libraries or applications, this problem can be fixed by copying `dialog.so` or `dialog.dll` from a MariaDB client installation that is compatible with the system into the system's MySQL client authentication plugin directory. However, not all clients are compatible with the `dialog` client authentication plugin, so this may not work for every client.

If your client does not support the `dialog` client authentication plugin, then you may need to use the mysql_clear_password client authentication plugin instead.

The `dialog` client authentication plugin transmits the password to the server in clear text. Therefore, when you use the `pam` authentication plugin, it is incredibly important to encrypt client connections using TLS to prevent the clear-text passwords from being seen by unauthorized users.

`mysql_clear_password`

Users can instruct the `pam` authentication plugin to use the `mysql_clear_password` client authentication plugin instead of the dialog client authentication plugin by configuring the pam_use_cleartext_plugin system variable on the server. It can be set in a relevant server option group in an option file:

```
[mariadb]
...
pam_use_cleartext_plugin
```

It is important to note that the `mysql_clear_password` plugin has very limited functionality.

- The `mysql_clear_password` client authentication plugin only supports PAM services that require password-based authentication.
- The `mysql_clear_password` client authentication plugin also only supports PAM services that ask the user a single question.
- If the PAM service requires challenge-responses, multiple questions, or other similar complicated authentication schemes, then the PAM service is not compatible with `mysql_clear_password` client authentication plugin. In that case, the dialog client authentication plugin will have to be used instead.

The `mysql_clear_password` client authentication plugin transmits the password to the server in clear text. Therefore, when you use the `pam` authentication plugin, it is incredibly important to encrypt client connections using

TLS to prevent the clear-text passwords from being seen by unauthorized users.

Compatibility with MySQL Clients and Client Libraries

The `mysql_clear_password` client authentication plugin is similar to MySQL's mysql_clear_password client authentication plugin.

The `mysql_clear_password` client authentication plugin is compatible with MySQL clients and most MySQL client libraries, while the dialog client authentication plugin is not always compatible with them. Therefore, the `mysql_clear_password` client authentication plugin is most useful if you need some kind of MySQL compatibility in your environment, but you still want to use the `pam` authentication plugin.

Even though the `mysql_clear_password` client authentication plugin is compatible with MySQL clients and most MySQL client libraries, the `mysql_clear_password` client authentication plugin may be disabled by default by these clients and client libraries. For example, MySQL's version of the mysql command-line client has the –enable-cleartext-plugin option that must be set in order to use the `mysql_clear_password` client authentication plugin:

```
mysql --enable-cleartext-plugin --user=alice -p
```

Other clients may require other methods to enable the authentication plugin. For example, MySQL Workbench has a checkbox titled **Enable Cleartext Authentication Plugin** under the **Advanced** tab on the connection configuration screen.

For applications that use MySQL's `libmysqlclient`, the authentication plugin can be enabled by setting the `MYSQL_ENABLE_CLEARTEXT_PLUGIN` option with the `mysql_options()` function:

```
mysql_options(mysql, MYSQL_ENABLE_CLEARTEXT_PLUGIN, 1);
```

For MySQL compatibility, MariaDB Connector/C also allows applications to set the `MYSQL_ENABLE_CLEARTEXT_PLUGIN` option with the mysql_optionsv function. However, this option does not actually do anything in MariaDB Connector/C, because the `mysql_clear_password` client authentication plugin is always enabled for MariaDB clients and client libraries.

Support in Client Libraries

Using the Plugin with MariaDB Connector/C

MariaDB Connector/C supports `pam` authentication using the client authentication plugins, regardless of the value of the pam_use_cleartext_plugin system variable.

Using the Plugin with MariaDB Connector/ODBC

MariaDB Connector/ODBC supports `pam` authentication using the client authentication plugins, regardless of the value of the pam_use_cleartext_plugin system variable.

Using the Plugin with MariaDB Connector/J

MariaDB Connector/J supports `pam v1` authentication, regardless of the value of the pam_use_cleartext_plugin system variable.

MariaDB Connector/J supports `pam v2` authentication, regardless of the value of the pam_use_cleartext_plugin system variable.

Using the Plugin with MariaDB Connector/Node.js

MariaDB Connector/Node.js supports `pam` authentication, regardless of the value of the pam_use_cleartext_plugin system variable.

Using the Plugin with MySqlConnector for .NET

MySqlConnector for ADO.NET supports `pam` authentication, but only if the pam_use_cleartext_plugin system variable is enabled on the server.

Logging

MariaDB PAM authentication can be collected from a variety of sources in the authentication framework, including the underlying PAM modules, the PAM authentication plugin, and custom scripts like pam_exec. The destination of these logs is decided by the layer that generated message and the configuration of your system.

PAM Module Logging

Errors and messages from PAM modules are usually logged using the syslog daemon with the `authpriv` facility. To determine the specific log file where the `authpriv` facility is logged, you can check rsyslog.conf.

On RHEL, CentOS, Fedora, and other similar Linux distributions, the default location for these messages is usually `/var/log/secure`.

On Debian, Ubuntu, and other similar Linux distributions, the default location for these messages is usually `/var/log/auth.log`.

For example, the syslog can contain messages like the following when MariaDB's `pam` authentication plugin is configured to use the pam_unix PAM module, and the user enters an incorrect password:

```
Jan  9 05:35:41 ip-172-30-0-198 unix_chkpwd[1205]: password check failed for user (foo)
Jan  9 05:35:41 ip-172-30-0-198 mysqld: pam_unix(mariadb:auth): authentication failure; logname= uid=997
euid=997 tty= ruser= rhost=  user=foo
```

PAM Authentication Plugin's Debug Logging

MariaDB's `pam` authentication plugin can also log additional verbose debug logging to the error log. This is only done if the plugin is a debug build and if pam_debug is set.

The output looks like this:

```
PAM: pam_start(mariadb, alice)
PAM: pam_authenticate(0)
PAM: conv: send(Enter PASSCODE:)
PAM: conv: recv(123456789)
PAM: pam_acct_mgmt(0)
PAM: pam_get_item(PAM_USER)
PAM: status = 0 user = ��\>
```

Custom Logging with pam_exec

The pam_exec PAM module can be used to implement some custom logging. This can be very useful when debugging certain kinds of issues.

For example, first, create a script that writes the log output:

```
tee /tmp/pam_log_script.sh <<EOF
#!/bin/bash
echo "\${PAM_SERVICE}:\${PAM_TYPE} - \${PAM_RUSER}@\${PAM_RHOST} is authenticating as \${PAM_USER}"
EOF
chmod 0775 /tmp/pam_log_script.sh
```

And, then, change the PAM service configuration to execute the script using the pam_exec PAM module. For example:

```
auth optional pam_exec.so log=/tmp/pam_output.txt /tmp/pam_log_script.sh
auth required pam_unix.so audit
account optional pam_exec.so log=/tmp/pam_output.txt /tmp/pam_log_script.sh
account required pam_unix.so audit
```

Whenever the above PAM service is used, the output of the script is written to `/tmp/pam_output.txt`. It looks similar to this output:

```
*** Tue May 14 14:53:23 2019
mariadb:auth - @ is authenticating as alice
*** Tue May 14 14:53:25 2019
mariadb:account - @ is authenticating as alice
*** Tue May 14 14:53:28 2019
mariadb:auth - @ is authenticating as alice
*** Tue May 14 14:53:31 2019
mariadb:account - @ is authenticating as alice
```

User and Group Mapping

Even when using the `pam` authentication plugin, the authenticating PAM user account still needs to exist in MariaDB, and the account needs to have privileges in the database. Creating these MariaDB accounts and making sure the privileges are correct can be a lot of work. To decrease the amount of work involved, some users would like to be able to map a PAM user to a different MariaDB user. For example, let's say that `alice` and `bob` are both DBAs. It would be nice if each of them could log into MariaDB with their own PAM username and password, while MariaDB sees both of them as the same `dba` user. That way, there is only one MariaDB account to keep track of. See User and Group Mapping with PAM for more information on how to do this.

PAM Modules

There are many PAM modules. The ones described below are the ones that have been seen most often by MariaDB. Several of them — including pam_sss, pam_winbind, pam_lsass, pam_centrifydc, and pam_krb5 — can authenticate against Microsoft Active Directory.

> **Note:**
>
> MariaDB supports the `pam` authentication plugin itself, not the individual PAM modules described below. These modules are third-party software, and the links to their documentation are provided for convenience only. MariaDB doesn't test, validate, or maintain them and can't list specific modules as officially supported. Consult each module's own documentation, and validate the configuration in your environment before relying on it in production.

pam_unix

The pam_unix PAM module provides support for Unix password authentication. It is the default PAM module on most systems.

For a tutorial on setting up PAM authentication and user or group mapping with Unix authentication, see Configuring PAM Authentication and User Mapping with Unix Authentication.

pam_user_map

The pam_user_map PAM module was developed by MariaDB to support user and group mapping.

pam_ldap

The pam_ldap PAM module provides support for LDAP authentication.

For a tutorial on setting up PAM authentication and user or group mapping with LDAP authentication, see Configuring PAM Authentication and User Mapping with LDAP Authentication.

This can also be configured for Active Directory authentication.

pam_sss

The pam_sss PAM module provides support for authentication with System Security Services Daemon (SSSD).

This can be configured for Active Directory authentication.

pam_lsass

The `pam_lsass` PAM module provides support for Active Directory authentication. It is provided by PowerBroker Identity Services – Open Edition.

pam_winbind

The pam_winbind PAM module provides support for Active Directory authentication. It is provided by winbindd from the samba suite.

This PAM module converts all provided user names to lowercase. There is no way to disable this functionality. If you do not want to be forced to use all lowercase user names, then you may need to configure the pam_winbind_workaround system variable. See MDEV-18686 for more information.

pam_centrifydc

The pam_centrifydc PAM module provides support for Active Directory authentication. It integrates with the commercial Active Directory Bridge from Centrify.

pam_krb5

The pam_krb5 PAM module provides support for Kerberos authentication.

This can be configured for Active Directory authentication.

pam_google_authenticator

The `pam_google_authenticator` PAM module provides two-factor identification with Google Authenticator. It is from Google's google-authenticator-libpam open-source project. The PAM module should work with the open-source mobile apps built by Google's google-authenticator and google-authenticator-android projects as well as the closed source Google Authenticator mobile apps that are present in each mobile app store.

For an example of how to use this PAM module, see the blog post: MariaDB: Improve Security with Two-Step Verification.

pam_securid

The `pam_securid` PAM module provides support for multi-factor authentication. It is part of the commercial RSA SecurID Suite.

Note that current versions of this module are not safe for multi-threaded environments, and the vendor does not officially support the product on MariaDB. See MDEV-10361 about that. However, the module may work with a current version of MariaDB.

pam_ssh

The pam_ssh PAM module provides authentication using SSH keys.

pam_time

The pam_time PAM module provides time-controlled access.

Known Issues

Multi-Threaded Issues

MariaDB is a multi-threaded program, which means that different connections concurrently run in different threads. Current versions of MariaDB's `pam` authentication plugin execute PAM module code in the server address space. This means that any PAM modules used with MariaDB must be safe for multi-threaded environments. Otherwise, if multiple clients try to authenticate with the same PAM module in parallel, undefined behavior can occur. For example, the `pam_fprintd` PAM module is not safe for multi-threaded environments, and if you use it with MariaDB, you may experience server crashes.

The `pam` authentication plugin isolates PAM module code from the server address space, so even PAM modules that are known to be unsafe for multi-threaded environments should not cause issues with MariaDB. See MDEV-15473 for more information.

Conflicts with Password Validation

When a password validation plugin is enabled, MariaDB won't allow an account to be created if the password validation plugin says that the account's password is too weak. This creates a problem for accounts that authenticate with the `pam` authentication plugin, since MariaDB has no knowledge of the user's password. When a user tries to create an account that authenticates with the `pam` authentication plugin, the password validation plugin would throw an error, even with strict_password_validation=OFF set.

The workaround is to uninstall the password validation plugin with UNINSTALL PLUGIN, and then create the account, and then reinstall the password validation plugin with INSTALL PLUGIN:

```
INSTALL PLUGIN simple_password_check SONAME 'simple_password_check';
Query OK, 0 rows affected (0.002 sec)

SET GLOBAL strict_password_validation=OFF;
Query OK, 0 rows affected (0.000 sec)

CREATE USER ''@'%' IDENTIFIED VIA pam USING 'mariadb';
ERROR 1819 (HY000): Your password does not satisfy the current policy requirements
UNINSTALL PLUGIN simple_password_check;
Query OK, 0 rows affected (0.000 sec)

CREATE USER ''@'%' IDENTIFIED VIA pam USING 'mariadb';
Query OK, 0 rows affected (0.000 sec)

INSTALL PLUGIN simple_password_check SONAME 'simple_password_check';
Query OK, 0 rows affected (0.001 sec)
```

> **Warning:**
>
> Accounts that authenticate with the `pam` authentication plugin should be exempt from password validation checks. See MDEV-12321 and MDEV-10457 for more information.

SELinux

SELinux may cause issues when using the `pam` authentication plugin. For example, using pam_unix with the `pam` authentication plugin while SELinux is enabled can sometimes lead to SELinux errors involving unix_chkpwd, such as the following::

```
Apr 14 12:37:59 localhost setroubleshoot: Plugin Exception restorecon_source
Apr 14 12:37:59 localhost setroubleshoot: SELinux is preventing /usr/sbin/unix_chkpwd from execute access
on the file . For complete SELinux messages. run sealert -l c56fe6e0-c78c-4bdb-a80f-27ef86a1ea85
Apr 14 12:37:59 localhost python: SELinux is preventing /usr/sbin/unix_chkpwd from execute access on the
file .

*****  Plugin catchall (100. confidence) suggests   *************************

If you believe that unix_chkpwd should be allowed execute access on the  file by default.
Then you should report this as a bug.
You can generate a local policy module to allow this access.
Do
allow this access for now by executing:
# grep unix_chkpwd /var/log/audit/audit.log | audit2allow -M mypol
# semodule -i mypol.pp
```

Sometimes issues like this can be fixed by updating the system's SELinux policies. You may be able to update the policies using audit2allow. See SELinux: Generating SELinux Policies with audit2allow for more information.

If you can't get the `pam` authentication plugin to work with SELinux at all, then it can help to disable SELinux entirely. See SELinux: Changing SELinux's Mode for information on how to do this.

Memory Overcommit

You may run into authentication failures with the following log message in the MariaDB error log:

```
pam: cannot exec /usr/lib64/mysql/plugin/auth_pam_tool_dir/auth_pam_tool (errno: 12 "Cannot allocate
memory")
```

This can happen on operating system setups that are configured to prevent memory overcommit. When the MariaDB server process spawns the `auth_pam_tool` helper process there's a brief period where the new process inherits the memory of the MariaDB process before releasing that memory and executing the new command. When having a MariaDB server configured to use more than 50% of the server machine's RAM — which is common for dedicated database servers — this duplication would lead to an over-commit situation.

> **CURRENT**
>
> Current MariaDB version use `posix_spawn()` instead of the classic `fork();exec()` to prevent memory overcommit issues. However, operating systems with older glibc versions (< 2.26) still use `fork();exec()` to implement `posix_spawn()` internally. Therefore, they are still affected; this is for example still the case on RedHat Enterprise Linux 7.
>
> **< 10.7.4 / 10.6.8 / 10.5.16**
>
> Older MariaDB versions still use `fork();exec()` , which means they are affected by the memory overcommit issue.

To solve this you can do this:

- Change the `vm.overcommit_memory` kernel setting to allow memory overcommit.
- Alternatively, install the older `auth_pam_v1` plugin version that does not spawn a helper process (but may run into problems with file permissions or multi threading with some PAM modules).

See also MDEV-26212 and MDEV-3073.

Tutorials

- Configuring PAM Authentication and User Mapping with Unix Authentication
- Configuring PAM Authentication and User Mapping with LDAP Authentication

System Variables

`pam_debug`

- Description: Enables verbose debug logging to the error log for all authentication handled by the plugin.
  - This system variable is only available when the plugin is a debug build.
- Command line: `--pam-debug`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`
- Introduced: MariaDB 10.2.2, MariaDB 10.1.17

`pam_use_cleartext_plugin`

- Description: Use the mysql_clear_password client authentication plugin instead of the dialog client authentication plugin. This may be needed for compatibility reasons, but it only supports simple PAM configurations that don't require any input besides a password.
- Command line: `--pam-use-cleartext-plugin`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`
- Introduced: MariaDB 10.1.1, MariaDB 5.5.32

`pam_winbind_workaround`

- Description: Configures the authentication plugin to compare the user name provided by the client with the user name returned by the PAM module in a case insensitive manner. This may be needed if you use the pam_winbind PAM module, which is known to convert all user names to lowercase, and which does not allow this behavior to be disabled.
- Command line: `--pam-winbind-workaround`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`
- Introduced: MariaDB 10.4.5, MariaDB 10.3.15, MariaDB 10.2.24, MariaDB 10.1.39

Options

`pam`

- Description: Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL

PLUGIN while the server is running.

- See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.

- Command line: `--pam=value`
- Data Type: `enumerated`
- Default Value: `ON`
- Valid Values: `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

Configuring PAM Authentication and User Mapping with LDAP Authentication

In this article, we will walk through the configuration of PAM authentication using the pam authentication plugin and user and group mapping with the pam_user_map PAM module. The primary authentication will be handled by the pam_ldap PAM module, which performs LDAP authentication. We will also set up an OpenLDAP server.

Hypothetical Requirements

In this walkthrough, we are going to assume the following hypothetical requirements:

- The LDAP user `foo` should be mapped to the MariaDB user `bar`. (`foo: bar`)
- Any LDAP user in the LDAP group `dba` should be mapped to the MariaDB user `dba`. (`@dba: dba`)

Setting up the OpenLDAP Server

Before we can use LDAP authentication, we first need to set up our OpenLDAP Server. This is usually done on a server that is completely separate from the database server.

Installing the OpenLDAP Server and Client Components

On the server acting as the OpenLDAP Server, first, we need to install the OpenLDAP components.

On RHEL, CentOS, and other similar Linux distributions that use RPM packages, that would go like this:

```
sudo yum install openldap openldap-servers openldap-clients nss-pam-ldapd
```

Configuring the OpenLDAP Server

Next, let's to configure the OpenLDAP Server. The easiest way to do that is to copy the template configuration file that is included with the installation. In many installations, that will be at `/usr/share/openldap-servers/DB_CONFIG.example`:

```
sudo cp /usr/share/openldap-servers/DB_CONFIG.example /var/lib/ldap/DB_CONFIG
sudo chown ldap. /var/lib/ldap/DB_CONFIG
```

Configuring the OpenLDAP Port

Sometimes it is useful to change the port used by OpenLDAP. For example, some cloud environments block well-known authentication services, so they block the default LDAP port.

On some systems, the port can be changed by setting `SLAPD_URLS` in `/etc/sysconfig/slapd`:

```
SLAPD_URLS="ldapi:/// ldap://0.0.0.0:3306/"
```

I used `3306` because that is the port that is usually used by `mysqld`, so I know that it is not blocked.

Starting the OpenLDAP Server

Next, let's start the OpenLDAP Server and configure it to start on reboot. On systemd systems, that would go like this:

```
sudo systemctl start slapd
sudo systemctl enable slapd
```

Installing the Standard LDAP objectClasses

In order to use LDAP for authentication, we also need to install some standard `objectClasses`, such as `posixAccount` and `posixGroup`. In LDAP, things like `objectClasses` are defined in LDIF files. In many installations, these specific `objectClasses` are defined in `/etc/openldap/schema/nis.ldif`. `nis.ldif` also depends on `core.ldif` and `cosine.ldif`. However, `core.ldif` is usually installed by default.

We can install them with ldapmodify:

```
sudo ldapmodify -a -Y EXTERNAL -H ldapi:/// -f /etc/openldap/schema/cosine.ldif
sudo ldapmodify -a -Y EXTERNAL -H ldapi:/// -f /etc/openldap/schema/nis.ldif
```

Creating the LDAP Directory Manager User

Next, let's create a directory manager user. We can do this by using OpenLDAP's olc configuration system to change the olcRootDN directive to the DN of the directory manager user, which means that the user will be a privileged LDAP user that is not subject to access controls. We will also set the root password for the user by changing the olcRootPW directive.

We will also set the DN suffix for our backend LDAP database by changing the olcSuffix directive.

Let's use the slappasswd utility to generate a password hash from a clear-text password. Simply execute:

```
slappasswd
```

This utility provides a password hash that looks like this: `{SSHA}AwT4jrvmokeCkbDrFAnGvzzjCMb7bvEl`

OpenLDAP's olc configuration system also uses LDIF files. Now that we have the password hash, let's create an `LDIF` file to create the directory manager user:

```
tee ~/setupDirectoryManager.ldif <<EOF
dn: olcDatabase={1}monitor,cn=config
changetype: modify
replace: olcAccess
olcAccess: {0}to *
    by dn.base="gidNumber=0+uidNumber=0,cn=peercred,cn=external,cn=auth" read
    by dn.base="cn=Manager,dc=support,dc=mariadb,dc=com" read
    by * none

dn: olcDatabase={2}hdb,cn=config
changetype: modify
replace: olcSuffix
olcSuffix: dc=support,dc=mariadb,dc=com

dn: olcDatabase={2}hdb,cn=config
changetype: modify
replace: olcRootDN
olcRootDN: cn=Manager,dc=support,dc=mariadb,dc=com

dn: olcDatabase={2}hdb,cn=config
changetype: modify
add: olcRootPW
olcRootPW: {SSHA}AwT4jrvmokeCkbDrFAnGvzzjCMb7bvEl

dn: olcDatabase={2}hdb,cn=config
changetype: modify
add: olcAccess
olcAccess: {0}to attrs=userPassword,shadowLastChange
    by   dn="cn=Manager,dc=support,dc=mariadb,dc=com" write
    by anonymous auth
    by self write
    by * none
olcAccess: {1}to dn.base=""
    by * read
olcAccess: {2}to *
    by dn="cn=Manager,dc=support,dc=mariadb,dc=com" write
    by * read
EOF
```

Note that this is using the `dc=support,dc=mariadb,dc=com` domain for the directory. You can change it to whatever is relevant to you.

Now let's run the `ldif` file with ldapmodify:

```
sudo ldapmodify -Y EXTERNAL -H ldapi:/// -f ~/setupDirectoryManager.ldif
```

We will use the new directory manager user to make changes to the LDAP directory after this step.

Creating the Structure of the Directory

Next, let's create the structure of the directory by creating parts of our tree.

```
tee ~/setupDirectoryStructure.ldif <<EOF
dn: dc=support,dc=mariadb,dc=com
objectClass: top
objectClass: dcObject
objectclass: organization
o: MariaDB Support Team
dc: support

dn: cn=Manager,dc=support,dc=mariadb,dc=com
objectClass: top
objectClass: organizationalRole
cn: Manager
description: Directory Manager

dn: ou=People,dc=support,dc=mariadb,dc=com
objectClass: top
objectClass: organizationalUnit
ou: People

dn: ou=Groups,dc=support,dc=mariadb,dc=com
objectClass: top
objectClass: organizationalUnit
ou: Groups

dn: ou=System Users,dc=support,dc=mariadb,dc=com
objectClass: top
objectClass: organizationalUnit
ou: System Users
EOF
```

Now, let's use our new directory manager user and run the LDIF file with ldapmodify:

```
ldapmodify -a -x -D cn=Manager,dc=support,dc=mariadb,dc=com -W -f ~/setupDirectoryStructure.ldif
```

Creating the LDAP Users and Groups

Let's go ahead and create the LDAP users and groups that we are using for this scenario.

First, let's create the `foo` user:

```
tee ~/createFooUser.ldif <<EOF
dn: uid=foo,ou=People,dc=support,dc=mariadb,dc=com
objectClass: top
objectClass: account
objectClass: posixAccount
objectClass: shadowAccount
cn: foo
uid: foo
uidNumber: 16859
gidNumber: 100
homeDirectory: /home/foo
loginShell: /bin/bash
gecos: foo
userPassword: {crypt}x
shadowLastChange: -1
shadowMax: -1
shadowWarning: 0
EOF
ldapmodify -a -x -D cn=Manager,dc=support,dc=mariadb,dc=com -W -f ~/createFooUser.ldif
```

Next, let's create a couple of users to go into the `dba` group:

```
tee ~/createDbaUsers.ldif <<EOF
dn: uid=gmontee,ou=People,dc=support,dc=mariadb,dc=com
objectClass: top
objectClass: account
objectClass: posixAccount
objectClass: shadowAccount
cn: gmontee
uid: gmontee
uidNumber: 16860
gidNumber: 100
homeDirectory: /home/gmontee
loginShell: /bin/bash
gecos: gmontee
userPassword: {crypt}x
shadowLastChange: -1
shadowMax: -1
shadowWarning: 0

dn: uid=bstillman,ou=People,dc=support,dc=mariadb,dc=com
objectClass: top
objectClass: account
objectClass: posixAccount
objectClass: shadowAccount
cn: bstillman
uid: bstillman
uidNumber: 16861
gidNumber: 100
homeDirectory: /home/bstillman
loginShell: /bin/bash
gecos: bstillman
userPassword: {crypt}x
shadowLastChange: -1
shadowMax: -1
shadowWarning: 0
EOF
ldapmodify -a -x -D cn=Manager,dc=support,dc=mariadb,dc=com -W -f ~/createDbaUsers.ldif
```

Note that each of these users needs a password, so we can set it for each user with ldappasswd:

```
ldappasswd -x -D cn=Manager,dc=support,dc=mariadb,dc=com -W -S
uid=foo,ou=People,dc=support,dc=mariadb,dc=com
ldappasswd -x -D cn=Manager,dc=support,dc=mariadb,dc=com -W -S
uid=gmontee,ou=People,dc=support,dc=mariadb,dc=com
ldappasswd -x -D cn=Manager,dc=support,dc=mariadb,dc=com -W -S
uid=bstillman,ou=People,dc=support,dc=mariadb,dc=com
```

Next, let's create our `dba` group:

```
tee ~/createDbaGroup.ldif <<EOF
dn: cn=dba,ou=Groups,dc=support,dc=mariadb,dc=com
objectClass: top
objectClass: posixGroup
gidNumber: 678
EOF
ldapmodify -a -x -D cn=Manager,dc=support,dc=mariadb,dc=com -W -f ~/createDbaGroup.ldif
```

Next, let's add our two users to it:

```
tee ~/addUsersToDbaGroup.ldif <<EOF
dn: cn=dba,ou=Groups,dc=support,dc=mariadb,dc=com
changetype: modify
add: memberuid
memberuid: gmontee

dn: cn=dba,ou=Groups,dc=support,dc=mariadb,dc=com
changetype: modify
add: memberuid
memberuid: bstillman
EOF
ldapmodify -a -x -D cn=Manager,dc=support,dc=mariadb,dc=com -W -f ~/addUsersToDbaGroup.ldif
```

We also need to create LDAP users with the same name as the `bar` and `dba` MariaDB users. See here to read more about the reasons to do so. No one will be logging in as these users, so they do not need passwords. Instead of the `People` `organizationalUnit`, we create them in the `System Users` `organizationalUnit`.

```
tee ~/createSystemUsers.ldif <<EOF
dn: uid=bar,ou=System Users,dc=support,dc=mariadb,dc=com
objectClass: top
objectClass: account
objectClass: posixAccount
objectClass: shadowAccount
cn: bar
uid: bar
uidNumber: 16862
gidNumber: 100
homeDirectory: /home/bar
loginShell: /bin/bash
gecos: bar
userPassword: {crypt}x
shadowLastChange: -1
shadowMax: -1
shadowWarning: 0

dn: uid=dba,ou=System Users,dc=support,dc=mariadb,dc=com
objectClass: top
objectClass: account
objectClass: posixAccount
objectClass: shadowAccount
cn: dba
uid: dba
uidNumber: 16863
gidNumber: 100
homeDirectory: /home/dba
loginShell: /bin/bash
gecos: dba
userPassword: {crypt}x
shadowLastChange: -1
shadowMax: -1
shadowWarning: 0
EOF
ldapmodify -a -x -D cn=Manager,dc=support,dc=mariadb,dc=com -W -f ~/createSystemUsers.ldif
```

Setting up the MariaDB Server

At this point, we can move on to setting up the MariaDB Server.

Installing LDAP and PAM Libraries

First, we need to make sure that the LDAP and PAM libraries are installed.

On RHEL, CentOS, and other similar Linux distributions that use RPM packages, we need to install the following packages:

```
sudo yum install openldap-clients nss-pam-ldapd pam pam-devel
```

Configuring LDAP

Next, let's configure LDAP on the system. We can use authconfig for this:

```
sudo authconfig --enableldap \
   --enableldapauth \
   --ldapserver="ldap://172.30.0.238:3306" \
   --ldapbasedn="dc=support,dc=mariadb,dc=com" \
   --enablemkhomedir \
   --update
```

Warning:

Be sure to replace `--ldapserver` and `--ldapbasedn` with values that are relevant for your environment.

Installing the pam_user_map PAM Module

CURRENT

The `pam_user_map` PAM module is included in the base install. No installation is needed.

< 10.5.2 / 10.4.13 / 10.3.23 / 10.2.32.7

Next, let's install the pam_user_map PAM module.

Before the module can be compiled from source, we may need to install some dependencies.

On RHEL, CentOS, and other similar Linux distributions that use RPM packages, we need to install `gcc` and `pam-devel`:

```
sudo yum install gcc pam-devel
```

On Debian, Ubuntu, and other similar Linux distributions that use DEB packages, we need to install `gcc` and `libpam0g-dev`:

```
sudo apt-get install gcc libpam0g-dev
```

And then we can build and install the library with the following:

```
wget https://raw.githubusercontent.com/MariaDB/server/10.4/plugin/auth_pam/mapper/pam_user_map.c
gcc pam_user_map.c -shared -lpam -fPIC -o pam_user_map.so
sudo install --mode=0755 pam_user_map.so /lib64/security/
```

Configuring the pam_user_map PAM Module

Next, let's configure the pam_user_map PAM module based on our hypothetical requirements.

The configuration file for the `pam_user_map` PAM module is `/etc/security/user_map.conf`. Based on our requirements, ours would look like:

```
foo: bar
@dba:dba
```

Installing the PAM Authentication Plugin

Next, let's install the pam authentication plugin.

Log into the MariaDB Server and execute the following:

```
INSTALL SONAME 'auth_pam';
```

Configuring the PAM Service

> **Note:**
>
> For modern Linux distributions (like RHEL 8 and newer) that use SSSD (System Security Services Daemon) to connect to an LDAP provider, the `pam_sss.so` module is the modern equivalent of `pam_ldap.so`. In such a configuration, `pam_sss.so` replaces `pam_ldap.so`. For more information, please see the Red Hat Enterprise Linux documentation.

Next, let's configure the PAM service. We will call our service `mariadb`, so our PAM service configuration file will be located at `/etc/pam.d/mariadb` on most systems.

Configuring PAM to Allow Only LDAP Authentication

Since we are only doing LDAP authentication with the pam_ldap PAM module and group mapping with the `pam_user_map` PAM module, our configuration file would look like this:

```
auth required pam_ldap.so
auth required pam_user_map.so
account required pam_ldap.so
```

Configuring PAM to Allow LDAP and Local Unix Authentication

If we want to allow authentication from LDAP users **and** from local Unix users through pam_unix, while giving priority to the local users, then we could do this instead:

```
auth [success=1 new_authtok_reqd=1 default=ignore] pam_unix.so audit
auth required pam_ldap.so try_first_pass
auth required pam_user_map.so
account sufficient pam_unix.so audit
account required pam_ldap.so
```

Configuring the pam_unix PAM Module

If you also want to allow authentication from local Unix users, the `pam_unix` PAM module adds some additional configuration steps on a lot of systems. We basically have to give the user that runs `mysqld` access to `/etc/shadow`.

If the `mysql` user is running `mysqld`, then we can do that by executing the following:

```
sudo groupadd shadow
sudo usermod -a -G shadow mysql
sudo chown root:shadow /etc/shadow
sudo chmod g+r /etc/shadow
```

The server needs to be restarted for this change to take affect.

Creating MariaDB Users

Next, let's create the MariaDB users. Remember that our PAM service is called `mariadb`.

First, let's create the MariaDB user for the user mapping: `foo: bar`

That means that we need to create a `bar` user:

```
CREATE USER 'bar'@'%' IDENTIFIED BY 'strongpassword';
GRANT ALL PRIVILEGES ON *.* TO 'bar'@'%' ;
```

And then let's create the MariaDB user for the group mapping: `@dba: dba`

That means that we need to create a `dba` user:

```
CREATE USER 'dba'@'%' IDENTIFIED BY 'strongpassword';
GRANT ALL PRIVILEGES ON *.* TO 'dba'@'%' ;
```

And then to allow for the user and group mapping, we need to create an anonymous user that authenticates with the pam authentication plugin that is also able to `PROXY` as the `bar` and `dba` users. Before we can create the proxy user, we might need to clean up some defaults:

```
DELETE FROM mysql.db WHERE User='' AND Host='%';
FLUSH PRIVILEGES;
```

And then let's create the anonymous proxy user:

```
CREATE USER ''@'%' IDENTIFIED VIA pam USING 'mariadb';
GRANT PROXY ON 'bar'@'%' TO ''@'%';
GRANT PROXY ON 'dba'@'%' TO ''@'%';
```

Testing our Configuration

Next, let's test our configuration by verifying that mapping is occurring. We can verify this by logging in as each of our users and comparing the return value of USER(), which is the original user name and the return value of CURRENT_USER(), which is the authenticated user name.

Testing LDAP Authentication

First, let's test our `foo` user:

```
$ mysql -u foo -h 172.30.0.198
[mariadb] Password:
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 134
Server version: 10.3.10-MariaDB MariaDB Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]> SELECT USER(), CURRENT_USER();
+-----------------------------------------------+----------------+
| USER()                                        | CURRENT_USER() |
+-----------------------------------------------+----------------+
| foo@ip-172-30-0-198.us-west-2.compute.internal | bar@%          |
+-----------------------------------------------+----------------+
1 row in set (0.000 sec)
```

We can verify that our `foo` LDAP user was properly mapped to the `bar` MariaDB user by looking at the return value of CURRENT_USER().

Then let's test our `gmontee` user in the `dba` group:

```
$ mysql -u gmontee -h 172.30.0.198
[mariadb] Password:
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 135
Server version: 10.3.10-MariaDB MariaDB Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]> SELECT USER(), CURRENT_USER();
+---------------------------------------------------+----------------+
| USER()                                            | CURRENT_USER() |
+---------------------------------------------------+----------------+
| gmontee@ip-172-30-0-198.us-west-2.compute.internal | dba@%          |
+---------------------------------------------------+----------------+
1 row in set (0.000 sec)
```

And then let's test our `bstillman` user in the `dba` group:

```
$ mysql -u bstillman -h 172.30.0.198
[mariadb] Password:
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 136
Server version: 10.3.10-MariaDB MariaDB Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]> SELECT USER(), CURRENT_USER();
+-----------------------------------------------------+----------------+
| USER()                                              | CURRENT_USER() |
+-----------------------------------------------------+----------------+
| bstillman@ip-172-30-0-198.us-west-2.compute.internal | dba@%          |
+-----------------------------------------------------+----------------+
1 row in set (0.000 sec)
```

We can verify that our `gmontee` and `bstillman` LDAP users in the `dba` LDAP group were properly mapped to the `dba` MariaDB user by looking at the return values of `CURRENT_USER()`.

Testing Local Unix Authentication

If you chose the option that also allowed local Unix authentication, then let's test that out. Let's create a Unix user and give the user a password real quick:

```
sudo useradd alice
sudo passwd alice
```

And let's also map this user to `dba`:

```
@dba:dba
foo: bar
alice: dba
```

And we know that the existing anonymous user already has the `PROXY` privilege granted to the `dba` user, so this should just work without any other configuration. Let's test it out:

```
$ mysql -u alice -h 172.30.0.198
[mariadb] Password:
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 141
Server version: 10.3.10-MariaDB MariaDB Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]> SELECT USER(), CURRENT_USER();
+-------------------------------------------------+----------------+
| USER()                                          | CURRENT_USER() |
+-------------------------------------------------+----------------+
| alice@ip-172-30-0-198.us-west-2.compute.internal | dba@%          |
+-------------------------------------------------+----------------+
1 row in set (0.000 sec)
```

We can verify that our `alice` Unix user was properly mapped to the `dba` MariaDB user by looking at the return values of CURRENT_USER().

Integrating with MariaDB MaxScale

If you are connecting to MariaDB Server through MariaDB MaxScale, it is also recommended to configure the proxy to authenticate users via MaxScale PAM Authenticator.

Configuring PAM Authentication and User Mapping with Unix Authentication

We walk through the configuration of PAM authentication using the pam authentication plugin and user and group mapping with the pam_user_map PAM module. The primary authentication will be handled by the pam_unix PAM module, which performs standard Unix password authentication.

Hypothetical Requirements

In this walkthrough, we are going to assume the following hypothetical requirements:

- The Unix user `foo` should be mapped to the MariaDB user `bar`. (`foo: bar`)
- Any Unix user in the Unix group `dba` should be mapped to the MariaDB user `dba`. (`@dba: dba`)

Creating Our Unix Users and Groups

Let's go ahead and create the Unix users and groups that we are using for this hypothetical scenario.

First, let's create the `foo` user and a couple users to go into the `dba` group. Note that each of these users needs a password.

```
sudo useradd foo
sudo passwd foo
sudo useradd alice
sudo passwd alice
sudo useradd bob
sudo passwd bob
```

Next, let's create the `dba` group and add our two users to it:

```
sudo groupadd dba
sudo usermod -a -G dba alice
sudo usermod -a -G dba bob
```

We also need to create Unix users with the same name as the `bar` and `dba` MariaDB users. See here to read more about why. No one will be logging in as these users, so they do not need passwords.

```
sudo useradd bar
sudo useradd dba -g dba
```

Installing the pam_user_map PAM Module

Next, let's install the pam_user_map PAM module.

Before the module can be compiled from source, we may need to install some dependencies.

On RHEL, CentOS, and other similar Linux distributions that use RPM packages, we need to install `gcc` and `pam-devel`:

```
sudo yum install gcc pam-devel
```

On Debian, Ubuntu, and other similar Linux distributions that use DEB packages, we need to install `gcc` and `libpam0g-dev`:

```
sudo apt-get install gcc libpam0g-dev
```

And then we can build and install the library with the following:

```
wget https://raw.githubusercontent.com/MariaDB/server/10.4/plugin/auth_pam/mapper/pam_user_map.c
gcc pam_user_map.c -shared -lpam -fPIC -o pam_user_map.so
sudo install --mode=0755 pam_user_map.so /lib64/security/
```

Configuring the pam_user_map PAM Module

Next, let's configure the pam_user_map PAM module based on our hypothetical requirements.

The configuration file for the `pam_user_map` PAM module is `/etc/security/user_map.conf`. Based on our hypothetical requirements, ours would look like:

```
foo: bar
@dba:dba
```

Installing the PAM Authentication Plugin

Next, let's install the pam authentication plugin.

Log into the MariaDB Server and execute the following:

```
INSTALL SONAME 'auth_pam';
```

Configuring the PAM Service

Next, let's configure the PAM service. We will call our service `mariadb`, so our PAM service configuration file will be located at `/etc/pam.d/mariadb` on most systems.

Since we are only doing Unix authentication with the `pam_unix` PAM module and group mapping with the `pam_user_map` PAM module, our configuration file would look like this:

```
auth required pam_unix.so audit
auth required pam_user_map.so
account required pam_unix.so audit
```

Configuring the pam_unix PAM Module

The `pam_unix` PAM module adds some additional configuration steps on a lot of systems. We basically have to give the user that runs `mysqld` access to `/etc/shadow`.

If the `mysql` user is running `mysqld`, then we can do that by executing the following:

```
sudo groupadd shadow
sudo usermod -a -G shadow mysql
sudo chown root:shadow /etc/shadow
sudo chmod g+r /etc/shadow
```

The server needs to be restarted for this change to take affect.

Creating MariaDB Users

Next, let's create the MariaDB users. Remember that our PAM service is called `mariadb`.

First, let's create the MariaDB user for the user mapping: `foo: bar` . This means we need to create a `bar` user:

```
CREATE USER 'bar'@'%' IDENTIFIED BY 'strongpassword';
GRANT ALL PRIVILEGES ON *.* TO 'bar'@'%' ;
```

Next, let's create the MariaDB user for the group mapping: `@dba: dba` . This means that we need to create a `dba` user:

```
CREATE USER 'dba'@'%' IDENTIFIED BY 'strongpassword';
GRANT ALL PRIVILEGES ON *.* TO 'dba'@'%' ;
```

Next, to allow for the user and group mapping, we need to create an anonymous user that authenticates with the pam authentication plugin that is also able to `PROXY` as the `bar` and `dba` users. Before we can create the proxy user, we might need to clean up some defaults:

```
DELETE FROM mysql.db WHERE User='' AND Host='%';
FLUSH PRIVILEGES;
```

Finally, let's create the anonymous proxy user:

```
CREATE USER ''@'%' IDENTIFIED VIA pam USING 'mariadb';
GRANT PROXY ON 'bar'@'%' TO ''@'%';
GRANT PROXY ON 'dba'@'%' TO ''@'%';
```

Testing our Configuration

Next, let's test out our configuration by verifying that mapping is occurring. We can verify this by logging in as each of our users and comparing the return value of USER(), which is the original user name and the return value of CURRENT_USER(), which is the authenticated user name.

First, let's test our `foo` user:

```
$ mysql -u foo -h 172.30.0.198
[mariadb] Password:
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 22
Server version: 10.3.10-MariaDB MariaDB Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]> SELECT USER(), CURRENT_USER();
+-----------------------------------------------+----------------+
| USER()                                        | CURRENT_USER() |
+-----------------------------------------------+----------------+
| foo@ip-172-30-0-198.us-west-2.compute.internal | bar@%          |
+-----------------------------------------------+----------------+
1 row in set (0.000 sec)
```

We can verify that our `foo` Unix user was properly mapped to the `bar` MariaDB user by looking at the return value of `CURRENT_USER()`.

Next, let's test our `alice` user in the `dba` group:

```
$ mysql -u alice -h 172.30.0.198
[mariadb] Password:
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 19
Server version: 10.3.10-MariaDB MariaDB Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]> SELECT USER(), CURRENT_USER();
+-------------------------------------------------+----------------+
| USER()                                          | CURRENT_USER() |
+-------------------------------------------------+----------------+
| alice@ip-172-30-0-198.us-west-2.compute.internal | dba@%          |
+-------------------------------------------------+----------------+
1 row in set (0.000 sec)
```

Finally, let's test our `bob` user in the `dba` group:

```
$ mysql -u bob -h 172.30.0.198
[mariadb] Password:
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 20
Server version: 10.3.10-MariaDB MariaDB Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]> SELECT USER(), CURRENT_USER();
+-----------------------------------------------+----------------+
| USER()                                        | CURRENT_USER() |
+-----------------------------------------------+----------------+
| bob@ip-172-30-0-198.us-west-2.compute.internal | dba@%          |
+-----------------------------------------------+----------------+
1 row in set (0.000 sec)
```

We can verify that our `alice` and `bob` Unix users in the `dba` Unix group were properly mapped to the `dba` MariaDB user by looking at the return values of `CURRENT_USER()`.

This page is licensed: CC BY-SA / Gnu FDL

User and Group Mapping with PAM

Overview

Even when using the pam authentication plugin, the authenticating PAM user account still needs to exist in MariaDB, and the account needs to have privileges in the database. Creating these MariaDB accounts and making sure the privileges are correct can be a lot of work. To decrease the amount of work involved, some users would like to be able to map a PAM user to a different MariaDB user. For example, let's say that `alice` and `bob` are both DBAs. It would be nice if each of them could log into MariaDB with their own PAM username and password, while MariaDB sees both of them as the same `dba` user. That way, there is only one MariaDB account to keep track of.

Although most PAM modules usually do not do things like this, PAM supports the ability to change the user name in the process of authentication.The MariaDB `pam` authentication plugin fully supports this feature of PAM.

The pam_user_map PAM Module

Rather than building user and group mapping into the `pam` authentication plugin, MariaDB thought that it would cover the most use cases and offer the most flexibility to offload this functionality to an external PAM module. The `pam_user_map` PAM module was implemented by MariaDB to facilitate this. This PAM module can be configured in the PAM service used by the `pam` authentication plugin, just like other PAM modules.

Lack of Support for MySQL/Percona Group Mapping Syntax

Unlike MariaDB, MySQL and Percona implemented group mapping in their PAM authentication plugins. If you've read through MySQL's PAM authentication documentation on group mapping or Percona's PAM authentication documentation on group mapping, you've probably seen syntax where the group mappings are provided in the CREATE USER statement like this:

```
CREATE USER ''@''
  IDENTIFIED WITH authentication_pam
  AS 'mysql, root=developer, users=data_entry';
```

Since MariaDB's user and group mapping is performed by an external PAM module, MariaDB's `pam` authentication plugin does not support this syntax. Instead, the user and group mappings for the `pam_user_map` PAM module are configured in an external configuration file. This is discussed in a later section.

Installing the pam_user_map PAM Module

The `pam_user_map` PAM module gets installed as part of all our MariaDB server packages.

Some Linux distributions have not picked up this change in their own packages yet. When using such an installation, it may be necessary to compile the PAM module from source as described in the next section, or to manually extract it from one of our server packages and copy it to the target system.

Installing the pam_user_map PAM Module from Source

Installing Compilation Dependencies

Before the module can be compiled from source, you may need to install some dependencies.

On RHEL, CentOS, and other similar Linux distributions that use RPM packages, you need to install `gcc`, `pam-devel` and `MariaDB-devel`:

```
sudo yum install gcc pam-devel MariaDB-devel
```

On Debian, Ubuntu, and other similar Linux distributions that use DEB packages, you need to install `gcc`, `libpam0g-dev`:

```
sudo apt-get install gcc libpam0g-dev libmariadb-dev
```

Compiling and Installing the pam_user_map PAM Module

The `pam_user_map` PAM module can be built by downloading `plugin/auth_pam/mapper/pam_user_map.c` file from the MariaDB source tree and compiling it after minor adjustments. Once it is built, it can be installed to the system's PAM module directory, which is typically `/lib64/security/`:

```
wget https://raw.githubusercontent.com/MariaDB/server/10.4/plugin/auth_pam/mapper/pam_user_map.c
sed -ie 's/config_auth_pam/plugin_auth_common/' pam_user_map.c
gcc -I/usr/include/mysql/ pam_user_map.c -shared -lpam -fPIC -o pam_user_map.so
sudo install --mode=0755 pam_user_map.so /lib64/security/
```

You also need to adjust the major version number in the URL on the first line to match your installed MariaDB version, and the `#-I` include path argument on the `gcc` line, as depending on operating system and MariaDB server version, the `plugin_auth_common.h` file may be installed in a directory other than `/usr/include/mysql/` .

Configuring the pam_user_map PAM Module

The `pam_user_map` PAM module uses the configuration file at the path `/etc/security/user_map.conf` to determine its user and group mappings. The file's format is described below.

To map a specific PAM user to a specific MariaDB user:

```
orig_pam_user_name: mapped_mariadb_user_name
```

Or to map any PAM user in a specific PAM group to a specific MariaDB user, the group name is prefixed with `@`:

```
@orig_pam_group_name: mapped_mariadb_user_name
```

For example, here is an example `/etc/security/user_map.conf`:

```
============================================================
#comments and empty lines are ignored
john: jack
bob:  admin
top:  accounting
@group_ro: readonly
```

Configuring PAM

With user and group mapping, configuring PAM is done similar to how it is normally done with the pam authentication plugin. However, when configuring the PAM service, you will have to add an `auth` line for the `pam_user_map` PAM module to the service's PAM configuration file:

```
auth required pam_unix.so audit
auth required pam_user_map.so
account required pam_unix.so audit
```

Creating Users

With user and group mapping, creating users is done similar to how it is normally done with the pam authentication plugin. However, one major difference is that you will need to GRANT the PROXY privilege on the mapped user to the original user.

Consider having the following configured in `/etc/security/user_map.conf`:

```
foo: bar
@dba:dba
```

Then you could execute the following to grant the relevant privileges:

```
CREATE USER 'bar'@'%' IDENTIFIED BY 'strongpassword';
GRANT ALL PRIVILEGES ON *.* TO 'bar'@'%' ;

CREATE USER 'dba'@'%' IDENTIFIED BY 'strongpassword';
GRANT ALL PRIVILEGES ON *.* TO 'dba'@'%' ;

CREATE USER ''@'%' IDENTIFIED VIA pam USING 'mariadb';
GRANT PROXY ON 'bar'@'%' TO ''@'%';
GRANT PROXY ON 'dba'@'%' TO ''@'%';
```

Note that the `''@'%'` account is a special catch-all anonymous account. Any login by a user that has no more specific account match in the system will be matched by this anonymous account.

Also note that you might not be able to create the `''@'%'` anonymous account by default on some systems without doing some extra steps first. See Fixing a Legacy Default Anonymous Account for more information.

Verifying that Mapping is Occurring

In case any user mapping is performed, the original user name is returned by the SQL function USER(), while the authenticated user name is returned by the SQL function CURRENT_USER(). The latter actually defines what privileges are available to a connected user.

Consider having the following configured:

```
foo: bar
```

Then the following output would verify that it is working properly:

```
$ mysql -u foo -h 172.30.0.198
[mariadb] Password:
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 22
Server version: 10.3.10-MariaDB MariaDB Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]> SELECT USER(), CURRENT_USER();
+-----------------------------------------------+----------------+
| USER()                                        | CURRENT_USER() |
+-----------------------------------------------+----------------+
| foo@ip-172-30-0-198.us-west-2.compute.internal | bar@%          |
+-----------------------------------------------+----------------+
1 row in set (0.000 sec)
```

We can verify that our `foo` PAM user was properly mapped to the `bar` MariaDB user by looking at the return value of `CURRENT_USER()`.

Logging

By default, the `pam_user_map` PAM module does not perform any logging. However, if you want to enable debug logging, then you can add the `debug` module argument to the service's PAM configuration file:

```
auth required pam_unix.so audit
auth required pam_user_map.so debug
account required pam_unix.so audit
```

When debug logging is enabled, the `pam_user_map` PAM module will write log entries to the same syslog location as other PAM modules, which is typically `/var/log/secure` on many systems.

For example, this debug log output can look like the following:

```
Jan  9 05:42:13 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): Opening file
'/etc/security/user_map.conf'.
Jan  9 05:42:13 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): Incoming username 'alice'.
Jan  9 05:42:13 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): User belongs to 2 groups [alice,dba].
Jan  9 05:42:13 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): Check if user is in group 'dba': YES
Jan  9 05:42:13 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): User mapped as 'dba'
Jan  9 05:43:36 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): Opening file
'/etc/security/user_map.conf'.
Jan  9 05:43:36 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): Incoming username 'bob'.
Jan  9 05:43:36 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): User belongs to 2 groups [bob,dba].
Jan  9 05:43:36 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): Check if user is in group 'dba': YES
Jan  9 05:43:36 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): User mapped as 'dba'
Jan  9 06:08:36 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): Opening file
'/etc/security/user_map.conf'.
Jan  9 06:08:36 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): Incoming username 'foo'.
Jan  9 06:08:36 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): User belongs to 1 group [foo].
Jan  9 06:08:36 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): Check if user is in group 'dba': NO
Jan  9 06:08:36 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): Check if username 'foo': YES
Jan  9 06:08:36 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): User mapped as 'bar'
```

Known Issues

PAM User with Same Name as Mapped MariaDB User Must Exist

With user and group mapping, any PAM user or any PAM user in a given PAM group can be mapped to a specific MariaDB user account. However, due to the way PAM works, a PAM user with the same name as the mapped MariaDB user account must exist.

Consider the configuration file for the PAM service file containing the following:

```
auth required pam_sss.so
auth required pam_user_map.so debug
account sufficient pam_unix.so
account sufficient pam_sss.so
```

Consider `etc/security/user_map.conf` containing the following:

```
@dba: dba
```

In that case, any PAM user in the PAM group `dba` are mapped to the MariaDB user account `dba`. But if a PAM user with the name `dba` doesn't exist, the `pam_user_map` PAM module's debug logging writes errors to the syslog, like the following:

```
Sep 27 17:17:05 dbserver1 mysqld: pam_user_map(mysql:auth): Opening file '/etc/security/user_map.conf'.
Sep 27 17:17:05 dbserver1 mysqld: pam_user_map(mysql:auth): Incoming username 'alice'.
Sep 27 17:17:05 dbserver1 mysqld: pam_user_map(mysql:auth): User belongs to 4 groups
[dba,mongod,mongodba,mysql].
Sep 27 17:17:05 dbserver1 mysqld: pam_user_map(mysql:auth): Check if user is in group 'mysql': YES
Sep 27 17:17:05 dbserver1 mysqld: pam_user_map(mysql:auth): User mapped as 'dba'
Sep 27 17:17:05 dbserver1 mysqld: pam_unix(mysql:account): could not identify user (from getpwnam(dba))
Sep 27 17:17:05 dbserver1 mysqld: pam_sss(mysql:account): Access denied for user dba: 10 (User not known
to the underlying authentication module)
Sep 27 17:17:05 dbserver1 mysqld: 2018-09-27 17:17:05 72 [Warning] Access denied for user
'alice'@'localhost' (using password: NO)
```

In the above log snippet, notice that both the `pam_unix` and the `pam_sss` PAM modules are complaining that the `dba` PAM user does not appear to exist, and that these complaints cause the PAM authentication process to fail, which causes the MariaDB authentication process to fail as well.

This can be fixed by creating a PAM user with the same name as the mapped MariaDB user account, which is `dba` in this case.

You may also be able to work around this problem by essentially disabling PAM's account verification for the service with the pam_permit PAM module. For example, in the above case, that would be:

```
auth required pam_sss.so
auth required pam_user_map.so debug
account required pam_permit.so
```

See MDEV-17315 for more information.

Authentication with JWT, OIDC, and OAuth 2.0 via PAM

> **Important:**
>
> This draft, intended for technical review under DOCS-5715, requires validation for technical accuracy. It includes generated text and code blocks and needs evaluation by a subject matter expert (SME) in this format. Please refrain from relying on any information on the page.

MariaDB Server supports modern authentication standards—including JSON Web Tokens (JWT), OpenID Connect (OIDC), and OAuth 2.0—through its pluggable authentication architecture.

By leveraging the operating system's PAM (Pluggable Authentication Modules) subsystem, MariaDB can integrate with external Identity Providers (IdPs) like AWS Cognito, Google Cloud Identity, and Azure AD without requiring proprietary database plugins. The database delegates the validation of tokens to the underlying OS security layer.

Prerequisites

Before proceeding, ensure the following components are available:

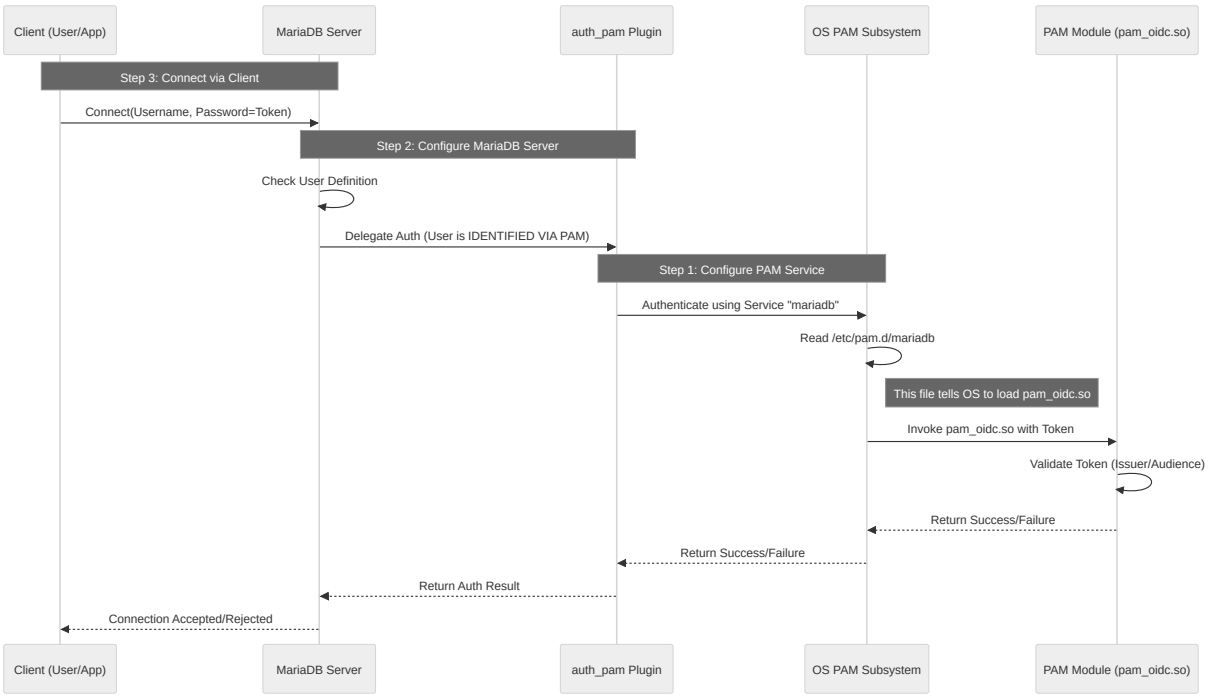
- MariaDB Server (Active and running).
- PAM Module: You must install a third-party PAM module corresponding to your desired authentication method (e.g., `pam_oidc.so`, `pam_oauth2.so`, or `pam_jwt.so`).
  - *Note: These are system-level libraries installed into `/lib/security` or `/lib64/security`. Ensure the module you choose is actively maintained and compatible with your OS.*
- Identity Provider (IdP): You must have your `Issuer URL`, `Client ID`, and `Audience` values ready from your provider (e.g., Google, Okta, Azure).

Configuration and Connection Workflow

How to bridge the operating system's authentication layer with MariaDB user management.

How Authentication Works

Before configuring the system, it is helpful to understand the handshake between the Client, the Database, and the Operating System.



Step 1

Configure the PAM Service

You must define a PAM service that loads your chosen module. This file tells the operating system how to validate the credentials passed by MariaDB.

File: `/etc/pam.d/mariadb`

The specific flags below (like `issuer` or `aud`) are standard OIDC parameters. Consult your specific PAM module's documentation for exact flag syntax.

```
# /etc/pam.d/mariadb
# Generic OIDC Configuration Example

# 1. 'auth' checks the validity of the token
auth required pam_oidc.so issuer=https://accounts.google.com aud=YOUR_CLIENT_ID

# 2. 'account' checks if the user is allowed to login (often required by PAM)
account required pam_oidc.so
```

Important:

Ensure strict validation of the `aud` (Audience) parameter to confirm that tokens are issued exclusively for your database application, preventing the use of tokens intended for different applications.

Step 2

Configure MariaDB Server

Once the OS is configured, you must enable the PAM plugin in MariaDB and create a user that utilizes it.

1. Log in to MariaDB as root.
2. Install the PAM Plugin:

   ```
   INSTALL SONAME 'auth_pam';
   ```

3. Create the User: The `USING` clause specifies the service name (filename) in `/etc/pam.d/`.

   ```
   -- Create a user that maps to the 'sub' (Subject) claim in the token
   CREATE USER 'jdoe'@'%' IDENTIFIED VIA pam USING 'mariadb';
   ```

Step 3

Connect via Client

When connecting, the "Password" field is used to transmit the JWT or OIDC Token.

```
# 1. Obtain your token (e.g., via gcloud or your IdP's CLI)
export DB_TOKEN="eyJhbGciOiJSUzI1NiIsImtpZ..."

# 2. Connect to MariaDB, passing the token as the password
mariadb --user="jdoe" --password="$DB_TOKEN"
```

Troubleshooting

- Authentication Failure: Check the system authentication logs.

  ```
  sudo tail -f /var/log/auth.log
  ```

  Look for errors regarding "invalid audience," "expired token," or "issuer mismatch."

- SELinux/AppArmor: If the database cannot access the PAM configuration, ensure your security context allows `mysqld` to read from `/etc/pam.d/`.
- Username Mapping: By default, the MariaDB username must match the identity in the token (often the `sub` or `email` claim). Some PAM modules allow you to map these (e.g., mapping `user@example.com` to `user`); check your module's `user_template` or mapping documentation.

MariaDB Replication & Cluster Plugins

See WSREP_INFO Plugin.

The WSREP_INFO plugin adds the WSREP_MEMBERSHIP and WSREP_STATUS tables to the Information Schema, providing detailed insights into Galera Cluster membership and status.

See wsrep_provider.

The wsrep_provider plugin exposes Galera Cluster provider options as individual system variables, allowing for easier configuration and validation of cluster settings.

This page is licensed: CC BY-SA / Gnu FDL

WSREP_INFO Plugin

The `WSREP_INFO` plugin library contains the following plugins:

- `WSREP_MEMBERSHIP`
- `WSREP_STATUS`

The `WSREP_MEMBERSHIP` plugin creates the WSREP_MEMBERSHIP table in the INFORMATION_SCHEMA database. The plugin also adds the SHOW WSREP_MEMBERSHIP statement.

The `WSREP_STATUS` plugin creates the WSREP_STATUS table in the INFORMATION_SCHEMA database. The plugin also adds the SHOW WSREP_STATUS statement.

These tables and statements provide information about Galera. Only users with the SUPER privilege can access this information.

Installing the Plugin

iAlthough the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN:

```
INSTALL SONAME 'wsrep_info';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the –plugin-load or the –plugin-load-add options. This can be specified as a command-line argument to mysqld or it can be specified in a relevant server option group in an option file:

```
[mariadb]
...
plugin_load_add = wsrep_info
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN:

```
UNINSTALL SONAME 'wsrep_info';
```

If you installed the plugin by providing the –plugin-load or the –plugin-load-add options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Example

```
SHOW TABLES FROM information_schema LIKE 'WSREP%';
+---------------------------------------+
| Tables_in_information_schema (WSREP%) |
+---------------------------------------+
| WSREP_STATUS                          |
| WSREP_MEMBERSHIP                      |
+---------------------------------------+
```

Options

`wsrep_membership`

- Description: Controls how the server treats the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- Command line: `--wsrep-membership=value`
- Data Type: `enumerated`
- Default Value: `ON`
- Valid Values: `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

`wsrep_status`

- Description: Controls how the server treats the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- Command line: `--wsrep-status=value`
- Data Type: `enumerated`
- Default Value: `ON`

- Valid Values: `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

This page is licensed: CC BY-SA / Gnu FDL

wsrep_provider

This plugin is for Galera Cluster. It splits up the `wsrep_provider_options` setting into individual configuration variables.

> **Note:**
>
> The plugin is available from MariaDB 11.4, and built in to the server, but not enabled by default.

Without that plugin, options are grouped together, like this:

```
wsrep_provider_options="base_dir = /var/lib/mysql/; base_host = node-1;..."
```

With this plugin loaded, you can configure individual variables, like this:

```
wsrep_provider_base_dir  = /var/lib/mysql/
wsrep_provider_base_host = node-1
...
```

This makes managing provider options easier, and helps avoid the problem of wsrep_provider_options exceeding the maximum length of 2048 characters for an individual variable.

To enable the plugin, add the following line to the `[mariadbd]`, `[server]`, or `[galera]` sections of your server option file:

```
plugin-wsrep-provider=ON
```

Alternatively, start the server with the `--plugin-wsrep-provider` option.

See the wsrep_provider_options page for what you can configure for Galera Cluster.

For plugin version and maturity level, see this page.

This page is licensed: CC BY-SA / Gnu FDL

Other Plugins

See Disks Plugin.

The Disks plugin adds the DISKS table to the Information Schema, providing metadata about the system's disk storage and usage.

See Feedback Plugin.

The Feedback plugin collects and sends anonymous server usage and configuration data to MariaDB to help improve the software.

See inet4.

The inet4 plugin provides the INET4 data type, allowing for efficient native storage and manipulation of IPv4 addresses as 4-byte binary strings.

See METADATA_LOCK_INFO Plugin.

This plugin creates the METADATA_LOCK_INFO table in the Information Schema, allowing users to view active metadata locks and their owners.

See MYSQL_JSON.

The MYSQL_JSON plugin provides a JSON data type alias for compatibility, ensuring that tables created with the MySQL JSON type can be read by MariaDB.

See mhnsw.

The mhnsw plugin implements the Hierarchical Navigable Small World algorithm, enabling high-performance approximate nearest neighbor search for vector data.

See online_alter_log.

The online_alter_log plugin provides logging capabilities for online ALTER TABLE operations, helping administrators monitor and debug schema changes.

See Query Cache Information Plugin.

This plugin exposes the contents of the query cache via the QUERY_CACHE_INFO table in the Information Schema, aiding in performance analysis.

See Query Response Time Plugin.

The Query Response Time plugin collects and displays the distribution of query execution times, helping to identify performance bottlenecks.

See User Variables Plugin.

The User Variables plugin adds the USER_VARIABLES table to the Information Schema, allowing users to inspect defined user variables and their values.

This page is licensed: CC BY-SA / Gnu FDL

Disks Plugin

The `DISKS` plugin creates the DISKS table in the INFORMATION_SCHEMA database. This table shows metadata about disks on the system, enabling monitoring of the disk space status. Accessing the `INFORMATION_SCHEMA.DISKS` table requires the FILE privilege.

> **Note:**
>
> The plugin is supported on Linux systems only.

Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB automatically. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN:

```
INSTALL SONAME 'disks';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the –plugin-load or the –plugin-load-add options. This can be provided as a command-line argument to mysqld or specified in a relevant server option group in an option file:

```
[mariadb]
...
plugin_load_add = disks
```

Example

After the plugin is installed, the `INFORMATION_SCHEMA.DISKS` table displays disk utilization information.

To view disk usage information, run the following query:

```
SELECT * FROM information_schema.DISKS;
```

Example Output

```
+-----------+----------------------+-----------+----------+-----------+
| Disk      | Path                 | Total     | Used     | Available |
+-----------+----------------------+-----------+----------+-----------+
| /dev/sda3 | /                    |  47929956 | 30666304 |  14805864 |
| /dev/sda1 | /boot/efi            |    191551 |     3461 |    188090 |
| /dev/sda4 | /home                | 174679768 | 80335392 |  85448120 |
| /dev/sdb1 | /mnt/hdd             | 961301832 |    83764 | 912363644 |
| /dev/sdb1 | /home/wikman/Music   | 961301832 |    83764 | 912363644 |
| /dev/sdb1 | /home/wikman/Videos  | 961301832 |    83764 | 912363644 |
| /dev/sdb1 | /home/wikman/hdd     | 961301832 |    83764 | 912363644 |
| /dev/sdb1 | /home/wikman/Pictures| 961301832 |    83764 | 912363644 |
| /dev/sda3 | /var/lib/docker/aufs |  47929956 | 30666304 |  14805864 |
+-----------+----------------------+-----------+----------+-----------+
9 rows in set (0.00 sec)
```

Column Descriptions

The `INFORMATION_SCHEMA.DISKS` table contains the following columns:

- **Disk**: The name of the disk device or partition.
- **Path**: The mount point where the disk is mounted.
- **Total**: The total disk space available on the disk (in KiB).
- **Used**: The amount of disk space currently used (in KiB).
- **Available**: The amount of disk space available to non-root users (in KiB).

> Note: As root users may have more available space than non-root users, `Available` + `Used` may be less than `Total`.
>
> Additionally, all paths to which a specific disk is mounted are reported, so a disk may appear multiple times in the output.

Alternative: Mounts Table

As an alternative option, the plugin includes the `INFORMATION_SCHEMA.MOUNTS` table, which contains mount points and their respective disks.

For example:

```
SELECT * FROM information_schema.MOUNTS;
```

Expected Output

```
+----------------------+-----------+
| Path                 | Disk      |
+----------------------+-----------+
| /                    | /dev/sda3 |
| /boot/efi            | /dev/sda1 |
| /home                | /dev/sda4 |
| /mnt/hdd             | /dev/sdb1 |
| /home/wikman/Music   | /dev/sdb1 |
+----------------------+-----------+
```

Versions

Version	Status	Introduced
1.1	Stable	MariaDB 10.4.7, MariaDB 10.3.17, MariaDB 10.2.26, MariaDB 10.1.41
1.0	Beta	MariaDB 10.3.6, MariaDB 10.2.14, MariaDB 10.1.32

Options

`disks`

- Description: Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- Command line: `--disks=value`
- Data Type: `enumerated`
- Default Value: `ON`
- Valid Values: `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN:

```
UNINSTALL SONAME 'disks';
```

If you installed the plugin by providing the –plugin-load or the –plugin-load-add options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Feedback Plugin

The `feedback` plugin is designed to collect and, optionally, upload configuration and usage information to MariaDB.org or to any other configured URL.

See the MariaDB User Feedback page on MariaDB.org to see collected MariaDB usage statistics.

MariaDB is usually distributed with this plugin included, but it is not enabled by default.
On Windows, this plugin is part of the server and has a special checkbox in the installer window. Either way, you need to explicitly install and enable it in order for feedback data to be sent.

Verifying the Plugin's Status

To verify whether the `feedback` plugin is installed and enabled, execute the SHOW PLUGINS statement or query the information_schema.plugins table:

```
SELECT plugin_status FROM information_schema.plugins
  WHERE plugin_name = 'feedback';
+---------------+
| plugin_status |
+---------------+
| DISABLED      |
+---------------+
```

If that `SELECT` returns no rows, then you still need to install the plugin.

When the plugin is installed and enabled, you will see:

```
SELECT plugin_status FROM information_schema.plugins
  WHERE plugin_name = 'feedback';
+---------------+
| plugin_status |
+---------------+
| ACTIVE        |
+---------------+
```

Installing the Plugin

In some releases, the plugin's shared library is distributed with MariaDB by default, but the plugin is not actually installed by MariaDB. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN:

```
INSTALL SONAME 'feedback';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the –plugin-load or the –plugin-load-add options. This can be specified as a command-line argument to mariadbd, or it can be specified in a relevant server option group in an option file:

```
[mariadb]
...
plugin_load_add = feedback
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN:

```
UNINSTALL SONAME 'feedback';
```

If you installed the plugin by providing the `--plugin-load` or the `--plugin-load-add` options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Enabling the Plugin

You can enable the plugin by setting the `feedback` option to `ON` in a relevant server option group in an option file:

```
[mariadb]
...
feedback=ON
```

In Windows, the plugin can also be enabled during a new MSI installation. The MSI GUI installation provides the "Enable feedback plugin" checkbox to enable the plugin. The MSI command-line installation provides the `FEEDBACK=1` command-line option to enable the plugin.

See the next section for how to verify the plugin is installed and active and (if needed) install the plugin.

Collecting Data

The `feedback` plugin collects the following data:

- Certain rows from SHOW STATUS and SHOW VARIABLES.
- All installed plugins and their versions.
- System information such as CPU count, memory, architecture, and OS/linux distribution.
- The feedback_server_uid, which is a SHA1 hash of the MAC address of the first network interface and the TCP port that the server listens on.

The `feedback` plugin creates the FEEDBACK table in the INFORMATION_SCHEMA database. To see the data that has been collected by the plugin, you can execute:

```
SELECT * FROM information_schema.feedback;
```

Only the contents of this table are sent to the feedback_url.

MariaDB stores collation usage statistics. Each collation that has been used by the server will have a record in output of `SELECT * FROM information_schema.feedback` , for example:

```
+---------------------------------------+---------------------+
| VARIABLE_NAME                         | VARIABLE_VALUE      |
+---------------------------------------+---------------------+
| Collation used utf8_unicode_ci        | 10                  |
| Collation used latin1_general_ci      | 20                  |
+---------------------------------------+---------------------+
```

Collations that have not been used will not be included in the result.

Sending Data

The `feedback` plugin sends the data using a `POST` request to any URL or a list of URLs that you specify by setting the feedback_url system variable. By default, this is set to the following URL:

- https://feedback.mariadb.org/rest/v1/post

Both HTTP and HTTPS protocols are supported.

If HTTP traffic requires a proxy in your environment, then you can specify the proxy by setting the feedback_http_proxy system variable.

If the feedback_url system variable is not set to an empty string, then the plugin will automatically send a report to all URLs in the list a few minutes after the server starts up and then once a week after that.

If the feedback_url system variable is set to an empty string, then the plugin will **not** automatically send any data. This may be necessary if outbound HTTP communication from your database server is not permitted. In this case, you can still upload the data manually, if you'd like.

First, generate the report file with the MariaDB command-line mariadb client:

```
$ mariadb -e 'select * from information_schema.feedback' > report.txt
```

Then, you can upload the generated `report.txt` here from the command line with tools such as curl:

```
$ curl -F data=@report.txt https://feedback.mariadb.org/rest/v1/post
```

Manual uploading allows you to be absolutely sure that we receive only the data shown in the INFORMATION_SCHEMA.FEEDBACK table and that no private or sensitive information is being sent.

System Variables

`feedback_http_proxy`

- Description: Proxy server for use when http calls cannot be made, such as in a firewall environment. The format is `host:port`.
- Command line: `--feedback-http=proxy=value`
- Read-only: Yes
- Data Type: string
- Default Value: `''` (empty)

`feedback_send_retry_wait`

- Description: Time in seconds before retrying if the plugin failed to send the data for any reason.
- Command line: `--feedback-send-retry-wait=#`
- Scope: Global
- Dynamic: Yes
- Data Type: numeric
- Default Value: `60`
- Valid Values: `1` to `86400`

`feedback_send_timeout`

- Description: An attempt to send the data times out and fails after this many seconds.
- Command line: `--feedback-send-timeout=#`
- Scope: Global
- Dynamic: Yes
- Data Type: numeric
- Default Value: `60`
- Valid Values: `1` to `86400`

`feedback_server_uid`

- Description: Automatically calculated server unique id hash.
- Scope: Global
- Dynamic: No
- Data Type: string

`feedback_url`

- Description: URL to which the data is sent. More than one URL, separated by spaces, can be specified. Set it to an empty string to disable data sending.
- Command line: `--feedback-url=url`
- Scope: Global
- Dynamic: No
- Data Type: string

- Default Value: https://feedback.mariadb.org/rest/v1/post

`feedback_user_info`

- Description: The value of this option is not used by the plugin, but it is included in the feedback data. It can be used to add any user-specified string to the report. This could be used to help to identify it. For example, a support contract number, or a computer name (if you collect reports internally by specifying your own `feedback-url`).
- Command line: `--feedback-user-info=string`
- Scope: Global
- Dynamic: No
- Data Type: string
- Default Value: Empty string

Options

`feedback`

- Description: Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- Command line: `--feedback=value`
- Data Type: `enumerated`
- Default Value: `ON`
- Valid Values: `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

inet4

This plugin implements the inet4 data type and functions used by this data type, like conversions.

> **Note:**
>
> For plugin version and maturity level, see this page.

This plugin is built in to MariaDB Server. It cannot be disabled.

`inet4` is a data type plugin. It can be used in stored procedures as a variable type and as a data type for table columns.

This page is licensed: CC BY-SA / Gnu FDL

METADATA_LOCK_INFO Plugin

The `METADATA_LOCK_INFO` plugin creates the METADATA_LOCK_INFO table in the INFORMATION_SCHEMA database. This table shows active metadata locks. The table is empty if there are no active metadata locks.

Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN:

```
INSTALL SONAME 'metadata_lock_info';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the –plugin-load or the –plugin-load-add options. This can be specified as a command-line argument to mysqld or it can be specified in a relevant server option group in an option file:

```
[mariadb]
...
plugin_load_add = metadata_lock_info
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN:

```
UNINSTALL SONAME 'metadata_lock_info';
```

If you installed the plugin by providing the –plugin-load or the –plugin-load-add options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Examples

Viewing all Metadata Locks

```
SELECT * FROM information_schema.metadata_lock_info;
+-----------+-------------------------+---------------+---------------------+-----------------+--------
-----+
| THREAD_ID | LOCK_MODE               | LOCK_DURATION | LOCK_TYPE           | TABLE_SCHEMA    |
TABLE_NAME  |
+-----------+-------------------------+---------------+---------------------+-----------------+--------
-----+
|        31 | MDL_INTENTION_EXCLUSIVE | MDL_EXPLICIT  | Global read lock    |                 |
|
|        31 | MDL_INTENTION_EXCLUSIVE | MDL_EXPLICIT  | Commit lock         |                 |
|
|        31 | MDL_INTENTION_EXCLUSIVE | MDL_EXPLICIT  | Schema metadata lock | dbname          |
|
|        31 | MDL_SHARED_NO_READ_WRITE | MDL_EXPLICIT  | Table metadata lock  | dbname          | exotics
|
+-----------+-------------------------+---------------+---------------------+-----------------+--------
-----+
4 rows in set (0.00 sec)
```

Matching Metadata Locks with Threads and Queries

```
SELECT
CONCAT('Thread ',P.ID,' executing "',P.INFO,'" IS LOCKED BY Thread ',
M.THREAD_ID) WhoLocksWho
FROM INFORMATION_SCHEMA.PROCESSLIST P,
INFORMATION_SCHEMA.METADATA_LOCK_INFO M
WHERE LOCATE(lcase(LOCK_TYPE), lcase(STATE))>0;
+-------------------------------------------------------------------------------------+
| WhoLocksWho                                                                         |
+-------------------------------------------------------------------------------------+
| Thread 3 executing "INSERT INTO foo ( b ) VALUES ( 'FOO' )" IS LOCKED BY Thread 2 |
+-------------------------------------------------------------------------------------+
1 row in set (0.00 sec)

SHOW PROCESSLIST;
+----+------+-----------+------+---------+------+-----------------------------+-----------------------
---------------+----------+
| Id | User | Host      | db   | Command | Time | State                       | Info
| Progress |
+----+------+-----------+------+---------+------+-----------------------------+-----------------------
---------------+----------+
|  2 | root | localhost | test | Sleep   |  123 |                             | NULL
|    0.000 |
|  3 | root | localhost | test | Query   |  103 | Waiting for global read lock | INSERT INTO foo ( b )
VALUES ( 'FOO' ) |    0.000 |
|  4 | root | localhost | test | Query   |    0 | init                        | SHOW PROCESSLIST
|    0.000 |
+----+------+-----------+------+---------+------+-----------------------------+-----------------------
---------------+----------+
3 rows in set (0.00 sec)
```

Options

`metadata_lock_info`

- Description: Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- Command line: `--metadata-lock-info=value`
- Data Type: `enumerated`
- Default Value: `ON`
- Valid Values: `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

MYSQL_JSON

> **Note:**
>
> The `TYPE_MYSQL_JSON` plugin is available from MariaDB 10.5.7.

The JSON type in MySQL stores the JSON object in its own native form, while, in MariaDB, the JSON type is a LONGTEXT. Opening a table with a JSON type created in MySQL results in an error:

```
SELECT * FROM mysql_json_table;
ERROR 4161 (HY000): Unknown data type: 'MYSQL_JSON'
```

The `mysql_json` plugin is used to make it easier to upgrade to MariaDB.

Installing

Installing can be done in a number of ways, for example:

```
INSTALL SONAME 'type_mysql_json';
```

See Making MariaDB understand MySQL JSON for a full description.

This page is licensed: CC BY-SA / Gnu FDL

mhnsw

> **Note:**
>
> This plugin is for internal use only.

This plugin implements the `nhnsw` vector index algorithm. It is used to create vector indexes.

See Vector Overview for the functionality, and Vector System Variables for what you can configure.

It is built in the server, and is always enabled.

For plugin version and maturity level, see this page.

This page is licensed: CC BY-SA / Gnu FDL

online_alter_log

> **Note:**
>
> This plugin is for internal use only.

This plugin represents the online alter log in a transaction. It is used to commit transactions for tables while an online `ALTER TABLE` query is running.

It is built in the server, and is always enabled.

See the Online Schema Change page for functionality details.

For plugin version and maturity level, see this page.

This page is licensed: CC BY-SA / Gnu FDL

Query Cache Information Plugin

The `QUERY_CACHE_INFO` plugin creates the QUERY_CACHE_INFO table in the INFORMATION_SCHEMA database. This table shows all queries in the query cache. Querying this table acquires the query cache lock and will result in lock waits for queries that are using or expiring from the query cache. You must have the PROCESS privilege to query this table.

Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN:

```
INSTALL SONAME 'query_cache_info';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the –plugin-load or the –plugin-load-add options. This can be specified as a command-line argument to mysqld or it can be specified in a relevant server option group in an option file:

```
[mariadb]
...
plugin_load_add = query_cache_info
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN:

```
UNINSTALL SONAME 'query_cache_info';
```

If you installed the plugin by providing the –plugin-load or the –plugin-load-add options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Example

```
SELECT statement_schema, statement_text, result_blocks_count,
  result_blocks_size FROM information_schema.query_cache_info;
+------------------+------------------+--------------------+--------------------+
| statement_schema | statement_text   | result_blocks_count | result_blocks_size |
+------------------+------------------+--------------------+--------------------+
| test             | SELECT * FROM t1 |                  1 |                512 |
+------------------+------------------+--------------------+--------------------+
```

Options

`query_cache_info`

- Description: Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- Command line: `--query-cache-info=value`
- Data Type: `enumerated`
- Default Value: `ON`

- Valid Values: `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

Query Response Time Plugin

The `query_response_time` plugin creates the QUERY_RESPONSE_TIME table in the INFORMATION_SCHEMA database. The plugin also adds the SHOW QUERY_RESPONSE_TIME and FLUSH QUERY_RESPONSE_TIME statements.

The slow query log provides exact information about queries that take a long time to execute. However, sometimes there are a large number of queries that each take a very short amount of time to execute. This feature provides a tool for analyzing that information by counting and displaying the number of queries according to the length of time they took to execute.

This feature is based on Percona's Response Time Distribution.

Installing the Plugin

> **CURRENT**
>
> This shared library actually consists of a number of different plugins:
>
> - `QUERY_RESPONSE_TIME` - An INFORMATION_SCHEMA plugin that exposes statistics.
> - `QUERY_RESPONSE_TIME_AUDIT` - audit plugin, collects statistics.
>
> Both plugins need to be installed to get meaningful statistics.
>
> In addition, these additional plugins are available:
>
> - `QUERY_RESPONSE_TIME_READ`
> - `QUERY_RESPONSE_TIME_READ_WRITE`
> - `QUERY_RESPONSE_TIME_WRITE`
>
> **< 11.5**
>
> This shared library actually consists of a number of different plugins:
>
> - `QUERY_RESPONSE_TIME` - An INFORMATION_SCHEMA plugin that exposes statistics.
> - `QUERY_RESPONSE_TIME_AUDIT` - audit plugin, collects statistics.
>
> Both plugins need to be installed to get meaningful statistics.

Although the plugin's shared library is distributed with MariaDB by default, the plugins are not actually installed by MariaDB by default. There are two methods that can be used to install the plugins with MariaDB.

The first method can be used to install the plugin library without restarting the server. You can install the plugins dynamically by executing INSTALL SONAME or INSTALL PLUGIN:

```
INSTALL SONAME 'query_response_time';
```

The second method can be used to tell the server to load the plugin library when it starts up. The plugins can be installed this way by providing the –plugin-load or the –plugin-load-add options. This can be specified as a command-line argument to mysqld or it can be specified in a relevant server option group in an option file:

```
[mariadb]
...
plugin_load_add = query_response_time
```

Note that in both cases you have to activate data collection by changing the query_response_time_stats setting to ON, it is OFF by default even when the plugin library is loaded.

You can change the setting at runtime with

```
SET GLOBAL query_response_time_stats=ON;
```

or in the options file after the plugin has been loaded:

```
[mariadb]
...
plugin_load_add = query_response_time
query_response_time_stats=ON;
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN:

```
UNINSTALL SONAME 'query_response_time';
```

If you installed the plugin by providing the –plugin-load or the –plugin-load-add options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Response Time Distribution

The user can define time intervals that divide the range 0 to positive infinity into smaller intervals and then collect the number of commands whose execution times fall into each of those intervals.

Each interval is described as:

```
(range_base ^ n; range_base ^ (n+1)]
```

The range_base is some positive number (see Limitations). The interval is defined as the difference between two nearby powers of the range base.

If the range base equals 10, we have the following intervals:

```
(0; 10 ^ -6], (10 ^ -6; 10 ^ -5], (10 ^ -5; 10 ^ -4], ...,
  (10 ^ -1; 10 ^1], (10^1; 10^2]...(10^7; positive infinity]
```

or

```
(0; 0.000001], (0.000001; 0.000010], (0.000010; 0.000100], ...,
  (0.100000; 1.0]; (1.0; 10.0]...(1000000; positive infinity]
```

For each interval, a count is made of the queries with execution times that fell into that interval.

You can select the range of the intervals by changing the range base. For example, for base range=2 we have the following intervals:

```
(0; 2 ^ -19], (2 ^ -19; 2 ^ -18], (2 ^ -18; 2 ^ -17], ...,
  (2 ^ -1; 2 ^1], (2 ^ 1; 2 ^ 2]...(2 ^ 25; positive infinity]
```

or

```
(0; 0.000001], (0.000001, 0.000003], ...,
  (0.25; 0.5], (0.5; 2], (2; 4]...(8388608; positive infinity]
```

Small numbers look strange (i.e., don't look like powers of 2), because we lose precision on division when the ranges are calculated at runtime. In the resulting table, you look at the high boundary of the range:

```
SELECT * FROM INFORMATION_SCHEMA.QUERY_RESPONSE_TIME;
+----------------+-------+----------------+
| TIME           | COUNT | TOTAL          |
+----------------+-------+----------------+
|       0.000001 |     0 |       0.000000 |
|       0.000010 |    17 |       0.000094 |
|       0.000100 |  4301 |       0.236555 |
|       0.001000 |  1499 |       0.824450 |
|       0.010000 | 14851 |      81.680502 |
|       0.100000 |  8066 |     443.635693 |
|       1.000000 |     0 |       0.000000 |
|      10.000000 |     0 |       0.000000 |
|     100.000000 |     1 |      55.937094 |
|    1000.000000 |     0 |       0.000000 |
|   10000.000000 |     0 |       0.000000 |
|  100000.000000 |     0 |       0.000000 |
| 1000000.000000 |     0 |       0.000000 |
| TOO LONG       |     0 | TOO LONG       |
+----------------+-------+----------------+
```

This means there were:

```
* 17 queries with 0.000001 < query execution time < = 0.000010 seconds; total execution time of the 17
queries = 0.000094 seconds

* 4301 queries with 0.000010 < query execution time < = 0.000100 seconds; total execution time of the
4301 queries = 0.236555 seconds

* 1499 queries with 0.000100 < query execution time < = 0.001000 seconds; total execution time of the
1499 queries = 0.824450 seconds

* 14851 queries with 0.001000 < query execution time < = 0.010000 seconds; total execution time of the
14851 queries = 81.680502 seconds

* 8066 queries with 0.010000 < query execution time < = 0.100000 seconds; total execution time of the
8066 queries = 443.635693 seconds

* 1 query with 10.000000 < query execution time < = 100.0000 seconds; total execution time of the 1 query
= 55.937094 seconds
```

Using the Plugin

Using the Information Schema Table

You can get the distribution by querying the QUERY_RESPONSE_TIME table in the INFORMATION_SCHEMA database:

```
SELECT * FROM INFORMATION_SCHEMA.QUERY_RESPONSE_TIME;
```

You can also write more complex queries:

```
SELECT c.count, c.time,
(SELECT SUM(a.count) FROM INFORMATION_SCHEMA.QUERY_RESPONSE_TIME AS a
   WHERE a.count != 0) AS query_count,
(SELECT COUNT(*)     FROM INFORMATION_SCHEMA.QUERY_RESPONSE_TIME AS b
  WHERE b.count != 0) AS not_zero_region_count,
(SELECT COUNT(*)     FROM INFORMATION_SCHEMA.QUERY_RESPONSE_TIME) AS region_count
FROM INFORMATION_SCHEMA.QUERY_RESPONSE_TIME AS c
  WHERE c.count > 0;
```

Note: If query_response_time_stats is set to `ON`, then the execution times for these two `SELECT` queries will also be collected.

Using the SHOW Statement

As an alternative to the QUERY_RESPONSE_TIME table in the INFORMATION_SCHEMA database, you can also use the SHOW QUERY_RESPONSE_TIME statement:

```
SHOW QUERY_RESPONSE_TIME;
```

Flushing Plugin Data

Flushing the plugin data does two things:

- Clears the collected times from the QUERY_RESPONSE_TIME table in the INFORMATION_SCHEMA database.
- Reads the value of query_response_time_range_base and uses it to set the range base for the table.

Plugin data can be flushed with the FLUSH QUERY_RESPONSE_TIME statement:

```
FLUSH QUERY_RESPONSE_TIME;
```

Setting the query_response_time_flush system variable has the same effect:

```
SET GLOBAL query_response_time_flush=1;
```

> **CURRENT**
>
> It is possible to specify flushing read and/or write statements with the `FLUSH QUERY_RESPONSE_TIME_READ`, `FLUSH QUERY_RESPONSE_TIME_WRITE` and `FLUSH QUERY_RESPONSE_TIME_READ_WRITE` statements.
>
> **< 11.5**
>
> It is **not** possible to specify flushing read and/or write statements with the `FLUSH QUERY_RESPONSE_TIME_READ`, `FLUSH QUERY_RESPONSE_TIME_WRITE` and `FLUSH QUERY_RESPONSE_TIME_READ_WRITE` statements.

System Variables

`query_response_time_flush`

- Description: Updating this variable flushes the statistics and re-reads query_response_time_range_base.
- Command line: None
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`query_response_time_range_base`

- Description: Select base of log for `QUERY_RESPONSE_TIME` ranges. WARNING: variable change takes affect only after flush.
- Command line: `--query-response-time-range-base=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`

- Default Value: `10`
- Range: `2` to `1000`

`query_response_time_exec_time_debug`

- Description: Pretend queries take this many microseconds. When 0 (the default) use the actual execution time.
  - This system variable is only available when the plugin is a debug build.
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `31536000`

`query_response_time_session_stats`

- Description: Controls query response time statistics collection for the current session: `ON` - enable, `OFF` - disable, `GLOBAL` (default) - use query_response_time_stats value.
- Command line: `query-response-time-session-stats=val]`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `enum`
- Default Value: `GLOBAL`
- Valid Values: `GLOBAL`, `ON`, `OFF`
- Introduced: MariaDB 11.5

`query_response_time_stats`

- Description: Enable or disable query response time statistics collecting.
- Command line: `query-response-time-stats[={0|1}]`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

Options

`query_response_time`

- Description: Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- Command line: `--query-response-time=value`

- Data Type: `enumerated`
- Default Value: `ON`
- Valid Values: `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

`query_response_time_audit`

- Description: Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- Command line: `--query-response-time-audit=value`
- Data Type: `enumerated`
- Default Value: `ON`
- Valid Values: `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

User Variables Plugin

The `user_variables` plugin creates the USER_VARIABLES table in the INFORMATION_SCHEMA database. This table contains information about user-defined variables.

Viewing

User-defined variables can be viewed by either querying the USER_VARIABLES, or by running `SHOW USER_VARIABLES`.

Flushing User-Defined Variables

User-defined variables are reset and the Information Schema table emptied with the FLUSH USER_VARIABLES statement.

Examples

```
SET @v1 = 0;
SET @v2 = 'abc';
SET @v3 = CAST(123 AS CHAR(5));

SHOW USER_VARIABLES;
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| v3            | 123   |
| v2            | abc   |
| v1            | 0     |
+---------------+-------+

SELECT * FROM information_schema.USER_VARIABLES ORDER BY VARIABLE_NAME;
+---------------+----------------+---------------+--------------------+
| VARIABLE_NAME | VARIABLE_VALUE | VARIABLE_TYPE | CHARACTER_SET_NAME |
+---------------+----------------+---------------+--------------------+
| v1            | 0              | INT           | latin1             |
| v2            | abc            | VARCHAR       | utf8               |
| v3            | 123            | VARCHAR       | utf8               |
+---------------+----------------+---------------+--------------------+

FLUSH USER_VARIABLES;

SELECT * FROM information_schema.USER_VARIABLES ORDER BY VARIABLE_NAME;
Empty set (0.000 sec)
```

Installing the Plugin

> **Note:**
>
> In current versions, the `user_variables` plugin is statically linked into the server by default, so it does not need to be installed.

If it is not installed, however, here are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN:

```
INSTALL SONAME 'user_variables';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the –plugin-load or the –plugin-load-add options. This can be specified as a command-line argument to mysqld or it can be specified in a relevant server option group in an option file:

```
[mariadb]
...
plugin_load_add = user_variables
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN:

```
UNINSTALL SONAME 'user_variables';
```

If you installed the plugin by providing the –plugin-load or the –plugin-load-add options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Options

`user_variables`

- Description: Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- Command line: `--user-variables=value`
- Data Type: `enumerated`
- Default Value: `ON`
- Valid Values: `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

Password Validation Plugins

See Password Validation Plugin Overview.

General introduction into plugins that enforce specific security policies and complexity rules for user passwords.

See Cracklib Password Check Plugin.

The Cracklib Password Check Plugin enforces password strength by validating new passwords against the CrackLib library and its dictionary.

See Password Reuse Check Plugin.

The Password Reuse Check Plugin prevents users from reusing previous passwords, with a retention policy controlled by the password_reuse_check_interval variable.

See password_reuse_check_interval Variable.

This system variable defines the retention period in days for the password history used by the Password Reuse Check Plugin to prevent reuse.

See Simple Password Check Plugin.

The Simple Password Check Plugin enforces basic password complexity rules, such as minimum length and required numbers of digits, letters, and special characters.

This page is licensed: CC BY-SA / Gnu FDL

Password Validation Plugin Overview

Password validation means ensuring that user passwords meet certain minimal security requirements. A dedicated plugin API allows the creation of password validation plugins that will check user passwords as they are set (in SET PASSWORD and GRANT statements) and either allow or reject them.

SQL-Level Extensions

MariaDB comes with three password validation plugins — the simple_password_check plugin, the cracklib_password_check plugin and the password_reuse_check plugin. They are not enabled by default – use INSTALL SONAME (or INSTALL PLUGIN) statement to install them.

When at least one password plugin is loaded, all new passwords will be validated and password-changing statements will fail if the password will not pass validation checks. Several password validation plugin can be loaded at the same time — in this case a password must pass **all** validation checks by **all** plugins.

Password-Changing Statements

One can use various SQL statements to change a user password:

With Plain Text Password

```
SET PASSWORD = PASSWORD('plain-text password');
SET PASSWORD FOR `user`@`host` = PASSWORD('plain-text password');
SET PASSWORD = OLD_PASSWORD('plain-text password');
SET PASSWORD FOR `user`@`host` = OLD_PASSWORD('plain-text password');
CREATE USER `user`@`host` IDENTIFIED BY 'plain-text password';
GRANT PRIVILEGES TO `user`@`host` IDENTIFIED BY 'plain-text password';
```

These statements are subject to password validation. If at least one password validation plugin is loaded, plain-text passwords specified in these statements will be validated.

With Password Hash

```
SET PASSWORD = 'password hash';
SET PASSWORD FOR `user`@`host` = 'password hash';
CREATE USER `user`@`host` IDENTIFIED BY PASSWORD 'password hash';
CREATE USER `user`@`host` IDENTIFIED VIA mysql_native_password USING 'password hash';
CREATE USER `user`@`host` IDENTIFIED VIA mysql_old_password USING 'password hash';
GRANT PRIVILEGES TO `user`@`host` IDENTIFIED BY PASSWORD 'password hash';
GRANT PRIVILEGES TO `user`@`host` IDENTIFIED VIA mysql_native_password USING 'password hash';
GRANT PRIVILEGES TO `user`@`host` IDENTIFIED VIA mysql_old_password USING 'password hash';
```

These statements can not possibly use password validation — there is nothing to validate, the original plain-text password is not available.

MariaDB introduces a **strict password validation** mode — controlled by a strict_password_validation global server variable.

If the strict password validation is enabled and at least one password validation plugin is loaded, passwords that cannot be validated are rejected; otherwise, they're accepted. By default, a strict password validation is enabled (but note that it has no effect if no password validation plugin is loaded).

Examples

Failed password validation:

```
GRANT SELECT ON *.* to foobar IDENTIFIED BY 'raboof';
ERROR HY000: Your password does not satisfy the current policy requirements

SHOW WARNINGS;
+---------+------+--------------------------------------------------------------+
| Level   | Code | Message                                                      |
+---------+------+--------------------------------------------------------------+
| Warning | 1819 | cracklib: it is based on your username                       |
| Error   | 1819 | Your password does not satisfy the current policy requirements |
+---------+------+--------------------------------------------------------------+
```

Strict password validation:

```
GRANT SELECT ON *.* TO foo IDENTIFIED BY PASSWORD '2222222222222222';
ERROR HY000: The MariaDB server is running with the --strict-password-validation option so it cannot
execute this statement
```

This page is licensed: CC BY-SA / Gnu FDL

Cracklib Password Check Plugin

`cracklib_password_check` is a password validation plugin. It uses the CrackLib library to check the strength of new passwords. CrackLib is installed by default in many Linux distributions, since the system's Pluggable Authentication Module (PAM) authentication framework is usually configured to check the strength of new passwords with the pam_cracklib PAM module.

Note that passwords can be directly set as a hash, bypassing the password validation, if the strict_password_validation variable is `OFF` (it is `ON` by default).

The plugin requires at least cracklib 2.9.0, so it is not available on Debian/Ubuntu builds before Debian 8 Jessie/Ubuntu 14.04 Trusty, RedHat Enterprise Linux / CentOS 6.

Installing the Plugin's Package

The `cracklib_password_check` plugin's shared library is included in MariaDB packages as the `cracklib_password_check.so` or `cracklib_password_check.dll` shared library on systems where it can be built.

Installing on Linux

The `cracklib_password_check` plugin is included in `systemd` binary tarballs on Linux, but not in the older generic and `glibc_214` tarballs.

Installing with a Package Manager

The `cracklib_password_check` plugin can also be installed via a package manager on Linux. In order to do so, your system needs to be configured to install from one of the MariaDB repositories.

You can configure your package manager to install it from MariaDB Corporation's MariaDB Package Repository by using the MariaDB Package Repository setup script.

You can also configure your package manager to install it from MariaDB Foundation's MariaDB Repository by using the MariaDB Repository Configuration Tool.

Installing with yum/dnf

On RHEL, CentOS, Fedora, and other similar Linux distributions, it is highly recommended to install the relevant RPM package from MariaDB's repository using yum or dnf. Starting with RHEL 8 and Fedora 22, `yum` has been replaced by `dnf`, which is the next major version of `yum`. However, `yum` commands still work on many systems that use `dnf`:

```
sudo yum install MariaDB-cracklib-password-check
```

Installing with apt-get

On Debian, Ubuntu, and other similar Linux distributions, it is highly recommended to install the relevant DEB package from MariaDB's repository using apt-get:

```
sudo apt-get install mariadb-plugin-cracklib-password-check
```

Installing with zypper

On SLES, OpenSUSE, and other similar Linux distributions, it is highly recommended to install the relevant RPM package from MariaDB's repository using zypper:

```
sudo zypper install MariaDB-cracklib-password-check
```

Installing the Plugin

Once the shared library is in place, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN:

```
INSTALL SONAME 'cracklib_password_check';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the –plugin-load or the –plugin-load-add options. This can be specified as a command-line argument to mariadbd, or it can be specified in a relevant server option group in an option file:

```
[mariadb]
...
plugin_load_add = cracklib_password_check
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN:

```
UNINSTALL SONAME 'cracklib_password_check';
```

If you installed the plugin by providing the –plugin-load or the –plugin-load-add options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Viewing CrackLib Errors

If password validation fails, then the original CrackLib error message can be viewed by executing SHOW WARNINGS.

Example

When creating a new password, if the criteria are not met, the following error is returned:

```
SET PASSWORD FOR 'bob'@'%.loc.gov' = PASSWORD('abc');
ERROR 1819 (HY000): Your password does not satisfy the current policy requirements
```

Known Issues

SELinux

When using the standard SELinux policy with the mode set to `enforcing`, `mariadbd` does not have access to `/usr/share/cracklib`, and you may see the following error when attempting to use the `cracklib_password_check` plugin:

```
CREATE USER `user`@`hostname` IDENTIFIED BY 's0mePwd123.';
ERROR 1819 (HY000): Your password does not satisfy the current policy requirements

SHOW WARNINGS;
+---------+------+--------------------------------------------------------------+
| Level   | Code | Message                                                      |
+---------+------+--------------------------------------------------------------+
| Warning | 1819 | cracklib: error loading dictionary                           |
| Error   | 1819 | Your password does not satisfy the current policy requirements |
| Error   | 1396 | Operation CREATE USER failed for 'user'@'hostname'            |
+---------+------+--------------------------------------------------------------+
```

And the SELinux `audit.log` contains errors like these:

```
type=AVC msg=audit(1548371977.821:66): avc:  denied  { read } for  pid=3537 comm="mysqld"
name="pw_dict.pwd" dev="xvda2" ino=564747 scontext=system_u:system_r:mysqld_t:s0
tcontext=system_u:object_r:crack_db_t:s0 tclass=file
type=SYSCALL msg=audit(1548371977.821:66): arch=c000003e syscall=2 success=no exit=-13 a0=7fdd2a674580
a1=0 a2=1b6 a3=1b items=0 ppid=1 pid=3537 auid=4294967295 uid=995 gid=992 euid=995 suid=995 fsuid=995
egid=992 sgid=992 fsgid=992 tty=(none) ses=4294967295 comm="mysqld" exe="/usr/sbin/mysqld"
subj=system_u:system_r:mysqld_t:s0 key=(null)
```

This can be fixed by creating an SELinux policy that allows `mysqld` to load the CrackLib dictionary:

```
cd /usr/share/mysql/policy/selinux/
tee ./mariadb-plugin-cracklib-password-check.te <<EOF

module mariadb-plugin-cracklib-password-check 1.0;

require {
        type mysqld_t;
        type crack_db_t;
        class file { execute setattr read create getattr execute_no_trans write ioctl open append unlink
};
        class dir { write search getattr add_name read remove_name open };
}

allow mysqld_t crack_db_t:dir { search read open };
allow mysqld_t crack_db_t:file { getattr read open };
EOF
sudo yum install selinux-policy-devel
make -f /usr/share/selinux/devel/Makefile mariadb-plugin-cracklib-password-check.pp
sudo semodule -i mariadb-plugin-cracklib-password-check.pp
```

See MDEV-18374 for more information.

System Variables

`cracklib_password_check_dictionary`

- Description: Sets the path to the CrackLib dictionary. If not set, the default CrackLib dictionary path is used. The parameter expects the base name of a cracklib dictionary (a set of three files with endings `.hwm`, `.pwd`, `.pwi`), not a directory path.
- Command line: `--cracklib-password-check-dictionary=value`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: Depends on the system. Often `/usr/share/cracklib/pw_dict`

Options

`cracklib_password_check`

- Description: Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- Command line: `--cracklib-password-check=value`
- Data Type: `enumerated`
- Default Value: `ON`
- Valid Values: `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

Password Reuse Check Plugin

> **Note:**
>
> `password_reuse_check` is available from MariaDB 10.7.0.

Description

The plugin is used to prevent a user from reusing a password, which can be a requirement in some security policies. The password_reuse_check_interval system variable determines the retention period, in days, for a password. By default, this is zero, meaning unlimited retention. Old passwords are stored in the mysql.password_reuse_check_history table.

Note that passwords can be directly set as a hash, bypassing the password validation, if the strict_password_validation variable is `OFF` (it is `ON` by default).

Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default.

You can install the plugin dynamically, without restarting the server, by executing INSTALL SONAME or INSTALL PLUGIN:

```
INSTALL SONAME 'password_reuse_check';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the –plugin-load or the –plugin-load-add options. This can be specified as a command-line

argument to mysqld or it can be specified in a relevant server option group in an option file:

```
[mariadb]
...
plugin_load_add = password_reuse_check
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN:

```
UNINSTALL SONAME 'password_reuse_check';
```

If you installed the plugin by providing the –plugin-load or the –plugin-load-add options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Example

```
INSTALL SONAME 'password_reuse_check';

GRANT SELECT ON *.* TO user1@localhost identified by 'pwd1';
Query OK, 0 rows affected (0.038 sec)

GRANT SELECT ON *.* TO user1@localhost identified by 'pwd1';
ERROR 1819 (HY000): Your password does not satisfy the current policy requirements

GRANT SELECT ON *.* TO user1@localhost identified by 'pwd2';
Query OK, 0 rows affected (0.003 sec)

GRANT SELECT ON *.* TO user1@localhost identified by 'pwd1';
ERROR 1819 (HY000): Your password does not satisfy the current policy requirements
```

Versions

Version	Status	Introduced
1.0	Alpha	MariaDB 10.7.0
1.0	Beta	MariaDB 10.7.2
1.0	Gamma	MariaDB 10.7.4
2.0	Stable	MariaDB 10.7.7, MariaDB 10.8.7, MariaDB 10.9.5, MariaDB 10.10.2

Warning:

The bump to version 2.0 required the change of the stored format to mitigate an implementation weakness (MDEV-28838) and as such the bump from 1.0 to 2.0 will invalidate previously saved password reuse protections.

password_reuse_check_interval Variable

The `password_reuse_check_interval` system variable is available when the password_reuse_check plugin is installed. It determines the retention period for the password history in days. Zero, the default, means that passwords are never discarded.

- Command line: `--password_reuse_check_interval=#`
- Scope: Global
- Read-only: No
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `36500`

This page is licensed: CC BY-SA / Gnu FDL

Simple Password Check Plugin

`simple_password_check` is a password validation plugin. It can check whether a password contains at least a certain number of characters of a specific type. When first installed, a password is required to be at least eight characters, and requires at least one digit, one uppercase character, one lowercase character, and one character that is neither a digit nor a letter.

Note that passwords can be directly set as a hash, bypassing the password validation, if the strict_password_validation variable is `OFF` (it is `ON` by default).

Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN:

```
INSTALL SONAME 'simple_password_check';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the –plugin-load or the –plugin-load-add options. This can be specified as a command-line argument to mariadbd, or it can be specified in a relevant server option group in an option file:

```
[mariadb]
...
plugin_load_add = simple_password_check
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN:

```
UNINSTALL SONAME 'simple_password_check';
```

If you installed the plugin by providing the –plugin-load or the –plugin-load-add options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Example

When creating a new password, if the criteria are not met, the following error is returned:

```
SET PASSWORD FOR 'bob'@'%.loc.gov' = PASSWORD('abc');
ERROR 1819 (HY000): Your password does not satisfy the current policy requirements
```

Known Issues

System Variables

`simple_password_check_digits`

- Description: A password must contain at least this many digits.
- Command line: `--simple-password-check-digits=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1`
- Range: `0` to `1000`

`simple_password_check_letters_same_case`

- Description: A password must contain at least this many upper-case and this many lower-case letters.
- Command line: `--simple-password-check-letters-same-case=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1`
- Range: `0` to `1000`

`simple_password_check_minimal_length`

- Description: A password must contain at least this many characters.
- Command line: `--simple-password-check-minimal-length=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `8`
- Range: `0` to `1000`

`simple_password_check_other_characters`

- Description: A password must contain at least this many characters that are neither digits nor letters.
- Command line: `--simple-password-check-other-characters=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1`
- Range: `0` to `1000`

Options

`simple_password_check`

- Description: Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.

        - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
        - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
        - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
    - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- Command line: `--simple-password-check=value`
- Data Type: `enumerated`
- Default Value: `ON`
- Valid Values: `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

System Tables

The MariaDB Server includes several system tables that store metadata about database objects, user privileges, and server status.

See Information Schema.

The `information_schema` is a standard-compliant database that provides information about all other databases, tables, and columns on the server.

See Performance Schema.

The `performance_schema` allows you to monitor server execution at a low level with minimal impact on performance.

See Sys Schema.

The `sys` schema contains a collection of views, procedures, and functions that simplify the interpretation of data from the `performance_schema`.

See The mysql Database Tables.

Contains the core system tables in the `mysql` database, including privilege tables, logging tables, and status variables.

This page is licensed: CC BY-SA / Gnu FDL

Information Schema

The `information_schema` is a standard-compliant database available in every MariaDB instance, providing metadata about all other databases, tables, columns, and server-level objects.

See Information Schema Tables.

Provides a comprehensive list of all tables available within the `information_schema`, including their purpose and the metadata they provide.

See TIME_MS column in INFORMATION_SCHEMA.PROCESSLIST.

Details the `TIME_MS` column in the `INFORMATION_SCHEMA.PROCESSLIST` table, which provides high-resolution timing for active server processes.

This page is licensed: CC BY-SA / Gnu FDL

TIME_MS column in INFORMATION_SCHEMA.PROCESSLIST

In MariaDB, an extra column `TIME_MS` was added to the INFORMATION_SCHEMA.PROCESSLIST table. This column shows the same information as the column '`TIME`', but in units of milliseconds with microsecond precision (the unit and precision of the `TIME` column is one second).

For details about microseconds support in MariaDB, see microseconds in MariaDB.

The value displayed in the `TIME` and `TIME_MS` columns is the period of time that the given thread has been in its current state. Thus, it can be used to check for example how long a thread has been executing the current query, or for how long it has been idle.

```
SELECT id, TIME, time_ms, command, state FROM
   information_schema.processlist, (SELECT sleep(2)) t;
+----+------+----------+---------+-----------+
| id | time | time_ms  | command | state     |
+----+------+----------+---------+-----------+
| 37 |    2 | 2000.493 | Query   | executing |
+----+------+----------+---------+-----------+
```

Note that as a difference to MySQL, in MariaDB the `TIME` column (and also the `TIME_MS` column) are not affected by any setting of @TIMESTAMP. This means that it can be reliably used also for threads that change `@TIMESTAMP` (such as the replication SQL thread). See also MySQL Bug #22047.

As a consequence of this, the `TIME` column of `SHOW FULL PROCESSLIST` and `INFORMATION_SCHEMA.PROCESSLIST` cannot be used to determine if a slave is lagging behind. For this, use instead the `Seconds_Behind_Master` column in the output of SHOW SLAVE STATUS.

The addition of the `TIME_MS` column is based on the microsec_process patch, developed by Percona.

Information Schema ALL_PLUGINS Table

Description

The Information Schema `ALL_PLUGINS` table contains information about server plugins, whether installed or not.

It contains the following columns:

Column	Description
PLUGIN_NAME	Name of the plugin.
PLUGIN_VERSION	Version from the plugin's general type descriptor.
PLUGIN_STATUS	Plugin status, one of ACTIVE, INACTIVE, DISABLED, DELETED or NOT INSTALLED.
PLUGIN_TYPE	Plugin type; STORAGE ENGINE, INFORMATION_SCHEMA, AUTHENTICATION, REPLICATION, DAEMON or AUDIT.
PLUGIN_TYPE_VERSION	Version from the plugin's type-specific descriptor.
PLUGIN_LIBRARY	Plugin's shared object file name, located in the directory specified by the plugin_dir system variable, and used by the INSTALL PLUGIN and UNINSTALL PLUGIN statements. NULL if the plugin is complied in and cannot be uninstalled.
PLUGIN_LIBRARY_VERSION	Version from the plugin's API interface.
PLUGIN_AUTHOR	Author of the plugin.
PLUGIN_DESCRIPTION	Description.
PLUGIN_LICENSE	Plugin's licence.
LOAD_OPTION	How the plugin was loaded; one of OFF, ON, FORCE or FORCE_PLUS_PERMANENT. See Installing Plugins.
PLUGIN_MATURITY	Plugin's maturity level; one of Unknown, Experimental, Alpha, Beta,'Gamma, and Stable.
PLUGIN_AUTH_VERSION	Plugin's version as determined by the plugin author. An example would be '0.99 beta 1'.

It provides a superset of the information shown by the SHOW PLUGINS SONAME statement, as well as the information_schema.PLUGINS table. For specific information about storage engines (a particular type of plugin), see the Information Schema ENGINES table and the SHOW ENGINES statement.

The table is not a standard Information Schema table, and is a MariaDB extension.

Example

```
SELECT * FROM information_schema.all_plugins\G
*************************** 1. row ***************************
           PLUGIN_NAME: binlog
        PLUGIN_VERSION: 1.0
         PLUGIN_STATUS: ACTIVE

Information Schema APPLICABLE_ROLES Table

The Information Schema `APPLICABLE_ROLES` table shows the role authorizations that the current user may use.

It contains the following columns:

Column	Description
GRANTEE	Account that the role was granted to.
ROLE_NAME	Name of the role.
IS_GRANTABLE	Whether the role can be granted or not.
IS_DEFAULT	Whether the role is the user's default role or not

The current role is in the ENABLED_ROLES Information Schema table.

Example

```
SELECT * FROM information_schema.APPLICABLE_ROLES;
+----------------+-------------+--------------+------------+
| GRANTEE        | ROLE_NAME   | IS_GRANTABLE | IS_DEFAULT |
+----------------+-------------+--------------+------------+
| root@localhost | journalist  | YES          | NO         |
| root@localhost | staff       | YES          | NO         |
| root@localhost | dd          | YES          | NO         |
| root@localhost | dog         | YES          | NO         |
+----------------+-------------+--------------+------------+
```

Information Schema CATALOG Table

> **Note:**
>
> This table is available as of MariaDB 12.0.

The Information Schema `CATALOG` table stores information about catalogs on the server.

It contains the following columns:

Column	Description
CATALOG_NAME	Catalog name.
DEFAULT_CHARACTER_SET_NAME	Default character set for the database.
DEFAULT_COLLATION_NAME	Default collation.
SCHEMA_COMMENT	Catalog comment

Example

```
MariaDB [def.test]> SELECT * FROM INFORMATION_SCHEMA.CATALOGS\G
*************************** 1. row ***************************
              CATALOG_NAME: c1
DEFAULT_CHARACTER_SET_NAME: latin1
    DEFAULT_COLLATION_NAME: latin1_swedish_ci
           CATALOG_COMMENT: This is catalog c1
*************************** 2. row ***************************
              CATALOG_NAME: cat2
DEFAULT_CHARACTER_SET_NAME: latin1
    DEFAULT_COLLATION_NAME: latin1_swedish_ci
           CATALOG_COMMENT:
*************************** 3. row ***************************
              CATALOG_NAME: def
DEFAULT_CHARACTER_SET_NAME: latin1
    DEFAULT_COLLATION_NAME: latin1_swedish_ci
           CATALOG_COMMENT: default catalog
...
```

Information Schema CHARACTER_SETS Table

The Information Schema `CHARACTER_SETS` table contains a list of supported character sets, their default collations and maximum lengths.

It contains the following columns:

Column	Description
CHARACTER_SET_NAME	Name of the character set.
DEFAULT_COLLATE_NAME	Default collation used.
DESCRIPTION	Character set description.
MAXLEN	Maximum length.

The SHOW CHARACTER SET statement returns the same results (although in a different order), and both can be refined in the same way. For example, the following two statements return the same results:

```
SHOW CHARACTER SET WHERE Maxlen LIKE '2';
```

and

```
SELECT * FROM information_schema.CHARACTER_SETS
WHERE MAXLEN LIKE '2';
```

See Setting Character Sets and Collations for details on specifying the character set at the server, database, table and column levels, and Supported Character Sets and Collations for a full list of supported characters sets and collations.

Example

```
SELECT CHARACTER_SET_NAME FROM information_schema.CHARACTER_SETS
WHERE DEFAULT_COLLATE_NAME LIKE '%chinese%';
+--------------------+
| CHARACTER_SET_NAME |
+--------------------+
| big5               |
| gb2312             |
| gbk                |
+--------------------+
```

Information Schema CHECK_CONSTRAINTS Table

The Information Schema `CHECK_CONSTRAINTS` table stores metadata about the constraints defined for tables in all databases.

It contains the following columns:

Column	Description
CONSTRAINT_CATALOG	Always contains the string 'def'.
CONSTRAINT_SCHEMA	Database name.
CONSTRAINT_NAME	Constraint name.
TABLE_NAME	Table name.
LEVEL	Type of the constraint ('Column' or 'Table'). From MariaDB 10.5.10.
CHECK_CLAUSE	Constraint clause.

Example

A table with a numeric table check constraint and with a default check constraint name:

```
CREATE TABLE t ( a INT, CHECK (a>10));
```

To see check constraint call `check_constraints` table from information schema.

```
SELECT * FROM INFORMATION_SCHEMA.CHECK_CONSTRAINTS\G
```

```
*************************** 1. row ***************************
CONSTRAINT_CATALOG: def
 CONSTRAINT_SCHEMA: test
   CONSTRAINT_NAME: CONSTRAINT_1
        TABLE_NAME: t
      CHECK_CLAUSE: `a` > 10
```

A new table check constraint called `a_upper`:

```
ALTER TABLE t ADD CONSTRAINT a_upper CHECK (a<100);
```

```
SELECT * FROM INFORMATION_SCHEMA.CHECK_CONSTRAINTS\G
```

```
*************************** 1. row ***************************
CONSTRAINT_CATALOG: def
 CONSTRAINT_SCHEMA: test
   CONSTRAINT_NAME: CONSTRAINT_1
        TABLE_NAME: t
     CHECK_CLAUSE: `a` > 10
*************************** 2. row ***************************
CONSTRAINT_CATALOG: def
 CONSTRAINT_SCHEMA: test
   CONSTRAINT_NAME: a_upper
        TABLE_NAME: t
     CHECK_CLAUSE: `a` < 100
```

A new table `tt` with a field check constraint called `b` , as well as a table check constraint called `b_upper`:

```
CREATE TABLE tt(b INT CHECK(b>0),CONSTRAINT b_upper CHECK(b<50));

SELECT * FROM INFORMATION_SCHEMA.CHECK_CONSTRAINTS;
+--------------------+-------------------+-----------------+------------+--------------+
| CONSTRAINT_CATALOG | CONSTRAINT_SCHEMA | CONSTRAINT_NAME | TABLE_NAME | CHECK_CLAUSE |
+--------------------+-------------------+-----------------+------------+--------------+
| def                | test              | b               | tt         | `b` > 0      |
| def                | test              | b_upper         | tt         | `b` < 50     |
| def                | test              | CONSTRAINT_1    | t          | `a` > 10     |
| def                | test              | a_upper         | t          | `a` < 100    |
+--------------------+-------------------+-----------------+------------+--------------+
```

Note: The name of the field constraint is the same as the field name.

After dropping the default table constraint called `CONSTRAINT_1`:

```
ALTER TABLE t DROP CONSTRAINT CONSTRAINT_1;

SELECT * FROM INFORMATION_SCHEMA.CHECK_CONSTRAINTS;
+--------------------+-------------------+-----------------+------------+--------------+
| CONSTRAINT_CATALOG | CONSTRAINT_SCHEMA | CONSTRAINT_NAME | TABLE_NAME | CHECK_CLAUSE |
+--------------------+-------------------+-----------------+------------+--------------+
| def                | test              | b               | tt         | `b` > 0      |
| def                | test              | b_upper         | tt         | `b` < 50     |
| def                | test              | a_upper         | t          | `a` < 100    |
+--------------------+-------------------+-----------------+------------+--------------+
```

Trying to insert invalid arguments into table `t` and `tt` generates an error.

```
INSERT INTO t VALUES (10),(20),(100);
ERROR 4025 (23000): CONSTRAINT `a_upper` failed for `test`.`t`

INSERT INTO tt VALUES (10),(-10),(100);
ERROR 4025 (23000): CONSTRAINT `b` failed for `test`.`tt`

INSERT INTO tt VALUES (10),(20),(100);
ERROR 4025 (23000): CONSTRAINT `b_upper` failed for `test`.`tt`
```

Note:

The following statement can be performed from MariaDB 10.5.10.

```
CREATE TABLE majra(CHECK(x>0), x INT, y INT CHECK(y < 0), z INT,
                            CONSTRAINT z CHECK(z>0), CONSTRAINT xyz CHECK(x<10 AND y<10 AND z<10));
Query OK, 0 rows affected (0.036 sec)

SHOW CREATE TABLE majra;

Information Schema CLIENT_STATISTICS Table

The Information Schema `CLIENT_STATISTICS` table holds statistics about client connections. This is part of the User Statistics feature, which is not enabled by default.

It contains the following columns:

Field	Type	Notes
CLIENT	VARCHAR(64)	The IP address or hostname the connection originated from.
TOTAL_CONNECTIONS	BIGINT(21)	The number of connections created for this client.
CONCURRENT_CONNECTIONS	BIGINT(21)	The number of concurrent connections for this client.
CONNECTED_TIME	BIGINT(21)	The cumulative number of seconds elapsed while there were connections from this client.

Field	Type	Notes
BUSY_TIME	DOUBLE	The cumulative number of seconds there was activity on connections from this client.
CPU_TIME	DOUBLE	The cumulative CPU time elapsed while servicing this client's connections. Note that this number may be wrong on SMP system if there was a CPU migration for the thread during the execution of the query.
BYTES_RECEIVED	BIGINT(21)	The number of bytes received from this client's connections.
BYTES_SENT	BIGINT(21)	The number of bytes sent to this client's connections.
BINLOG_BYTES_WRITTEN	BIGINT(21)	The number of bytes written to the binary log from this client's connections.
ROWS_READ	BIGINT(21)	The number of rows read by this client's connections.
ROWS_SENT	BIGINT(21)	The number of rows sent by this client's connections.
ROWS_DELETED	BIGINT(21)	The number of rows deleted by this client's connections.
ROWS_INSERTED	BIGINT(21)	The number of rows inserted by this client's connections.
ROWS_UPDATED	BIGINT(21)	The number of rows updated by this client's connections.
KEY_READ_HITS	BIGINT(21)	From MariaDB 11.5
KEY_READ_MISSES	BIGINT(21)	From MariaDB 11.5
SELECT_COMMANDS	BIGINT(21)	The number of SELECT commands executed from this client's connections.
UPDATE_COMMANDS	BIGINT(21)	The number of UPDATE commands executed from this client's connections.
OTHER_COMMANDS	BIGINT(21)	The number of other commands executed from this client's connections.
COMMIT_TRANSACTIONS	BIGINT(21)	The number of COMMIT commands issued by this client's connections.
ROLLBACK_TRANSACTIONS	BIGINT(21)	The number of ROLLBACK commands issued by this client's connections.
DENIED_CONNECTIONS	BIGINT(21)	The number of connections denied to this client.
LOST_CONNECTIONS	BIGINT(21)	The number of this client's connections that were terminated uncleanly.
ACCESS_DENIED	BIGINT(21)	The number of times this client's connections issued commands that were denied.
EMPTY_QUERIES	BIGINT(21)	The number of times this client's connections sent queries that returned no results to the server.
TOTAL_SSL_CONNECTIONS	BIGINT(21)	The number of TLS connections created for this client.
MAX_STATEMENT_TIME_EXCEEDED	BIGINT(21)	The number of times a statement was aborted, because it was executed longer than its MAX_STATEMENT_TIME threshold.

Example

```
SELECT * FROM information_schema.CLIENT_STATISTICS\G
*************************** 1. row ***************************
                CLIENT: localhost
     TOTAL_CONNECTIONS: 3
CONCURRENT_CONNECTIONS: 0
        CONNECTED_TIME: 4883
             BUSY_TIME: 0.009722
              CPU_TIME: 0.0102131
        BYTES_RECEIVED: 841
            BYTES_SENT: 13897
  BINLOG_BYTES_WRITTEN: 0
             ROWS_READ: 0
             ROWS_SENT: 214
          ROWS_DELETED: 0
         ROWS_INSERTED: 207
          ROWS_UPDATED: 0
       SELECT_COMMANDS: 10
       UPDATE_COMMANDS: 0
        OTHER_COMMANDS: 13
   COMMIT_TRANSACTIONS: 0
 ROLLBACK_TRANSACTIONS: 0
    DENIED_CONNECTIONS: 0
      LOST_CONNECTIONS: 0
         ACCESS_DENIED: 0
         EMPTY_QUERIES: 1
```

Information Schema COLLATION_CHARACTER_SET_APPLICABILITY Table

The Information Schema `COLLATION_CHARACTER_SET_APPLICABILITY` table shows which character sets are associated with which collations.

It contains the following columns:

Column	Description
COLLATION_NAME	Collation name.
CHARACTER_SET_NAME	Name of the associated character set.
FULL_COLLATION_NAME	Name of the associated character set/collation combination.
ID	The unique identifier of this character set/collation combination.
IS_DEFAULT	If the collation is the default for this character set.

The COLLATIONS table is table of the base `COLLATION_NAMES` in the same way that CHARACTER_SETS table is table of the base `CHARACTER_SET_NAMES`. The `COLLATION_CHARACTER_SET_APPLICABILITY` table is the mapping between collations and character sets.

When joining the information_schema.TABLES table with its field `TABLE_COLLATIONS`, this should be joined to `FULL_COLLATION_NAME` in the `COLLATION_CHARACTER_SET_APPLICABILITY` table.

See Setting Character Sets and Collations for details on specifying the character set at the server, database, table and column levels.

Example

```
SELECT * FROM information_schema.COLLATION_CHARACTER_SET_APPLICABILITY  WHERE
  CHARACTER_SET_NAME='utf32' ORDER BY IS_DEFAULT DESC, ID LIMIT 10;
+--------------------+--------------------+--------------------+-----+------------+
| COLLATION_NAME     | CHARACTER_SET_NAME | FULL_COLLATION_NAME | ID  | IS_DEFAULT |
+--------------------+--------------------+--------------------+-----+------------+
| utf32_general_ci   | utf32              | utf32_general_ci    |  60 | Yes        |
| utf32_bin          | utf32              | utf32_bin           |  61 |            |
| utf32_unicode_ci   | utf32              | utf32_unicode_ci    | 160 |            |
| utf32_icelandic_ci | utf32              | utf32_icelandic_ci  | 161 |            |
| utf32_latvian_ci   | utf32              | utf32_latvian_ci    | 162 |            |
| utf32_romanian_ci  | utf32              | utf32_romanian_ci   | 163 |            |
| utf32_slovenian_ci | utf32              | utf32_slovenian_ci  | 164 |            |
| utf32_polish_ci    | utf32              | utf32_polish_ci     | 165 |            |
| utf32_estonian_ci  | utf32              | utf32_estonian_ci   | 166 |            |
| utf32_spanish_ci   | utf32              | utf32_spanish_ci    | 167 |            |

Information Schema COLLATIONS Table

The Information Schema `COLLATIONS` table contains a list of supported collations.

It contains the following columns:

Column	Description
COLLATION_NAME	Name of the collation.
CHARACTER_SET_NAME	Associated character set.
ID	Collation id.
IS_DEFAULT	Whether the collation is the character set's default.
IS_COMPILED	Whether the collation is compiled into the server.
SORTLEN	Sort length, used for determining the memory used to sort strings in this collation.
PAD_ATTRIBUTE	
COMMENT	

The SHOW COLLATION statement returns the same results and both can be reduced in a similar way.

CURRENT

The following two statements return the same results:

```
SHOW COLLATION WHERE Charset LIKE 'utf8mb3';
```

```
SELECT * FROM information_schema.COLLATIONS
WHERE CHARACTER_SET_NAME LIKE 'utf8mb3';
```

< 10.5

The following two statements return the same results:

```
SHOW COLLATION WHERE Charset LIKE 'utf8';
```

```
SELECT * FROM information_schema.COLLATIONS
WHERE CHARACTER_SET_NAME LIKE 'utf8';
```

NO PAD Collations

`NO PAD` collations regard trailing spaces as normal characters. You can get a list of all `NO PAD` collations as follows:

CURRENT

```
SELECT collation_name FROM information_schema.COLLATIONS
WHERE pad_attribute = "NO PAD";
+------------------------------+
| collation_name               |
+------------------------------+
| big5_chinese_nopad_ci        |
| big5_nopad_bin               |
...
```

< 12.1

```
SELECT collation_name FROM information_schema.COLLATIONS
WHERE collation_name LIKE "%nopad%";
+------------------------------+
| collation_name               |
+------------------------------+
| big5_chinese_nopad_ci        |
| big5_nopad_bin               |
...
```

In comparisons, `NO PAD` collations evaluate to `0` (`FALSE`). Example:

```
SELECT 'a ' = 'a';
+------------+
| 'a ' = 'a' |
+------------+
|          0 |
+------------+
```

PAD SPACE Collations

`PAD SPACE` collations pad strings to equal lengths in comparisons, so that the comparison evaluates to `1` (`TRUE`). Example:

```
SELECT 'a ' = 'a';
+------------+
| 'a ' = 'a' |
+------------+
|          1 |
+------------+
```

Example

```
SELECT * FROM information_schema.COLLATIONS;
+-----------------------------+--------------------+------+------------+-------------+---------+
| COLLATION_NAME              | CHARACTER_SET_NAME | ID   | IS_DEFAULT | IS_COMPILED | SORTLEN |
+-----------------------------+--------------------+------+------------+-------------+---------+
| big5_chinese_ci             | big5               |    1 | Yes        | Yes         |       1 |
| big5_bin                    | big5               |   84 |            | Yes         |       1 |
| big5_chinese_nopad_ci       | big5               | 1025 |            | Yes         |       1 |
| big5_nopad_bin              | big5               | 1108 |            | Yes         |       1 |
| dec8_swedish_ci             | dec8               |    3 | Yes        | Yes         |       1 |
| dec8_bin                    | dec8               |   69 |            | Yes         |       1 |
| dec8_swedish_nopad_ci       | dec8               | 1027 |            | Yes         |       1 |
| dec8_nopad_bin              | dec8               | 1093 |            | Yes         |       1 |
| cp850_general_ci            | cp850              |    4 | Yes        | Yes         |       1 |
| cp850_bin                   | cp850              |   80 |            | Yes         |       1 |
...
```

Information Schema COLUMN_PRIVILEGES Table

The Information Schema `COLUMN_PRIVILEGES` table contains column privilege information derived from the mysql.columns_priv grant table.

It has the following columns:

Column	Description
GRANTEE	In the format user_name@host_name.
TABLE_CATALOG	Always def.
TABLE_SCHEMA	Database name.
TABLE_NAME	Table name.
COLUMN_NAME	Column name.
PRIVILEGE_TYPE	One of SELECT, INSERT, UPDATE or REFERENCES.
IS_GRANTABLE	Whether the user has the GRANT OPTION for this privilege.

Similar information can be accessed with the SHOW FULL COLUMNS and SHOW GRANTS statements. See the GRANT statement for details about privileges.

This information is also stored in the columns_priv table, in the `mysql` system database.

For a description of the privileges that are shown in this table, see column privileges.

Example

In the following example, no column-level privilege has been explicitly assigned:

```
SELECT * FROM information_schema.COLUMN_PRIVILEGES;
Empty SET
```

This page is licensed: CC BY-SA / Gnu FDL

Information Schema COLUMNS Table

The Information Schema `COLUMNS` table provides information about columns in each table on the server.

It contains the following columns:

Column	Description
TABLE_CATALOG	Always contains the string `'def'`.
TABLE_SCHEMA	Database name.
TABLE_NAME	Table name.
COLUMN_NAME	Column name.
ORDINAL_POSITION	Column position in the table. Can be used for ordering.
COLUMN_DEFAULT	Default value for the column. Literals are quoted to distinguish them from expressions. `NULL` means that the column has no default.
IS_NULLABLE	Whether the column can contain `NULL` values.
DATA_TYPE	The column's data type.
CHARACTER_MAXIMUM_LENGTH	Maximum length.
CHARACTER_OCTET_LENGTH	Same as the `CHARACTER_MAXIMUM_LENGTH` except for multi-byte character sets.
NUMERIC_PRECISION	For numeric types, the precision (number of significant digits) for the column. `NULL` if not a numeric field.
NUMERIC_SCALE	For numeric types, the scale (significant digits to the right of the decimal point). `NULL` if not a numeric field.
DATETIME_PRECISION	Fractional-seconds precision, or `NULL` if not a time data type.
CHARACTER_SET_NAME	Character set if a non-binary string data type, otherwise `NULL`.
COLLATION_NAME	Collation if a non-binary string data type, otherwise `NULL`.
COLUMN_TYPE	Column definition, a MySQL and MariaDB extension.
COLUMN_KEY	Index type. `PRI` for primary key, `UNI` for unique index, `MUL` for multiple index. A MySQL and MariaDB extension.
CREATE_OPTIONS	Extra CREATE TABLE options.This column is available from MariaDB 13.0.
EXTRA	Additional information about a column, for example whether the column is an invisible column, or `WITHOUT SYSTEM VERSIONING` if the table is not a system-versioned table. A MySQL and MariaDB extension.
PRIVILEGES	Which privileges you have for the column. A MySQL and MariaDB extension.
COLUMN_COMMENT	Column comments.
IS_GENERATED	Indicates whether the column value is generated (virtual, or computed). Can be `ALWAYS` or `NEVER`.
GENERATION_EXPRESSION	The expression used for computing the column value in a generated (virtual, or computed) column.
IS_SYSTEM_TIME_PERIOD_START	From MariaDB 11.4.1.
IS_SYSTEM_TIME_PERIOD_END	From MariaDB 11.4.1.

It provides information similar to, but more complete, than SHOW COLUMNS or output from mariadb-show.

Examples

```
SELECT * FROM information_schema.COLUMNS\G
...
*************************** 9. row ***************************
           TABLE_CATALOG: def
            TABLE_SCHEMA: test
              TABLE_NAME: t2
             COLUMN_NAME: j
        ORDINAL_POSITION: 1
          COLUMN_DEFAULT: NULL
             IS_NULLABLE: YES
               DATA_TYPE: longtext
CHARACTER_MAXIMUM_LENGTH: 4294967295
  CHARACTER_OCTET_LENGTH: 4294967295
       NUMERIC_PRECISION: NULL
           NUMERIC_SCALE: NULL
      DATETIME_PRECISION: NULL
      CHARACTER_SET_NAME: utf8mb4
          COLLATION_NAME: utf8mb4_bin
             COLUMN_TYPE: longtext
              COLUMN_KEY:
                   EXTRA:
              PRIVILEGES: select,insert,update,references
          COLUMN_COMMENT:
            IS_GENERATED: NEVER
   GENERATION_EXPRESSION: NULL
...
```

```
CREATE TABLE t (
  s1 VARCHAR(20) DEFAULT 'ABC',
  s2 VARCHAR(20) DEFAULT (concat('A','B')),
  s3 VARCHAR(20) DEFAULT ("concat('A','B')"),
  s4 VARCHAR(20),
  s5 VARCHAR(20) DEFAULT NULL,
  s6 VARCHAR(20) NOT NULL,
  s7 VARCHAR(20) DEFAULT 'NULL' NULL,
  s8 VARCHAR(20) DEFAULT 'NULL' NOT NULL
);

SELECT
  table_name,
  column_name,
  ordinal_position,
  column_default,
  column_default IS NULL
FROM information_schema.COLUMNS
WHERE table_schema=DATABASE()
AND TABLE_NAME='t';
+------------+-------------+------------------+----------------------+------------------------+
| table_name | column_name | ordinal_position | column_default       | column_default IS NULL |
+------------+-------------+------------------+----------------------+------------------------+
| t          | s1          |                1 | 'ABC'                |                      0 |
| t          | s2          |                2 | concat('A','B')      |                      0 |
| t          | s3          |                3 | 'concat(''A'',''B'')' |                      0 |
| t          | s4          |                4 | NULL                 |                      0 |
| t          | s5          |                5 | NULL                 |                      0 |
| t          | s6          |                6 | NULL                 |                      1 |
| t          | s7          |                7 | 'NULL'               |                      0 |
| t          | s8          |                8 | 'NULL'               |                      0 |
+------------+-------------+------------------+----------------------+------------------------+
```

In the results above, the two single quotes in `concat(''A'',''B'')` indicate an escaped single quote - see string-literals. Note that while mariadb client appears to show the same default value for columns `s5` and `s6`, the first is a 4-character string “NULL”, while the second is the SQL `NULL` value.

Note:

The following statement is available from MariaDB 11.3.

```
CREATE TABLE t(
     x INT,
     start_timestamp TIMESTAMP(6) GENERATED ALWAYS AS ROW START,
     end_timestamp TIMESTAMP(6) GENERATED ALWAYS AS ROW END,
     PERIOD FOR SYSTEM_TIME(start_timestamp, end_timestamp)
) WITH SYSTEM VERSIONING;

SELECT TABLE_NAME, COLUMN_NAME, ORDINAL_POSITION,
  IS_SYSTEM_TIME_PERIOD_START, IS_SYSTEM_TIME_PERIOD_END
  FROM INFORMATION_SCHEMA.COLUMNS WHERE TABLE_NAME='t'\G
*************************** 1. row ***************************
                TABLE_NAME: t
               COLUMN_NAME: x
          ORDINAL_POSITION: 1
IS_SYSTEM_TIME_PERIOD_START: NO
  IS_SYSTEM_TIME_PERIOD_END: NO
*************************** 2. row ***************************
                TABLE_NAME: t
               COLUMN_NAME: start_timestamp
          ORDINAL_POSITION: 2
IS_SYSTEM_TIME_PERIOD_START: YES
  IS_SYSTEM_TIME_PERIOD_END: NO
*************************** 3. row ***************************
                TABLE_NAME: t
               COLUMN_NAME: end_timestamp
          ORDINAL_POSITION: 3
IS_SYSTEM_TIME_PERIOD_START: NO
  IS_SYSTEM_TIME_PERIOD_END: YES
```

Information Schema DISKS Table

Warning:

The plugin only works on Linux.

Description

The `DISKS` table is created when the DISKS plugin is enabled, and shows metadata about disks on the system.

CURRENT

This plugin requires the FILE privilege.

< 10.4.7 / 10.3.17 / 10.2.26 / 10.1.41

Important:

This plugin does **not** check user privileges. When it is enabled, **any** user can query the `INFORMATION_SCHEMA.DISKS` table and see all the information it provides.

The table contains the following columns:

Column	Description
DISK	Name of the disk itself.
PATH	Mount point of the disk.

Column	Description
TOTAL	Total space in KiB.
USED	Used amount of space in KiB.
AVAILABLE	Amount of space in KiB available to non-root users.

Note that as the amount of space available to root (OS user) may be more that what is available to non-root users, ‘available’ + ‘used’ may be less than ‘total’.

All paths to which a particular disk has been mounted are reported. The rationale is that someone might want to take different action e.g. depending on which disk is relevant for a particular path. This leads to the same disk being reported multiple times.

Example

```
SELECT * FROM information_schema.DISKS;

+-----------+-------+----------+---------+-----------+
| Disk      | Path  | Total    | Used    | Available |
+-----------+-------+----------+---------+-----------+
| /dev/vda1 | /     | 26203116 | 2178424 |  24024692 |
| /dev/vda1 | /boot | 26203116 | 2178424 |  24024692 |
| /dev/vda1 | /etc  | 26203116 | 2178424 |  24024692 |
+-----------+-------+----------+---------+-----------+
```

Information Schema ENABLED_ROLES Table

The Information Schema `ENABLED_ROLES` table shows the enabled roles for the current session.

It contains the following column:

Column	Description
ROLE_NAME	The enabled role name, or NULL.

This table lists all roles that are currently enabled, one role per row — the current role, roles granted to the current role, roles granted to these roles and so on. If no role is set, the row contains a `NULL` value.

The roles that the current user can enable are listed in the APPLICABLE_ROLES Information Schema table.

See also CURRENT_ROLE().

Examples

```
SELECT * FROM information_schema.ENABLED_ROLES;
+-----------+
| ROLE_NAME |
+-----------+
| NULL      |
+-----------+

SET ROLE staff;

SELECT * FROM information_schema.ENABLED_ROLES;
+-----------+
| ROLE_NAME |
+-----------+
| staff     |
+-----------+
```

This page is licensed: CC BY-SA / Gnu FDL

Information Schema ENGINES Table

The Information Schema `ENGINES` table displays status information about the server's storage engines.

It contains the following columns:

Column	Description
ENGINE	Name of the storage engine.
SUPPORT	Whether the engine is the default, or is supported or not.
COMMENT	Storage engine comments.
TRANSACTIONS	Whether or not the engine supports transactions.
XA	Whether or not the engine supports XA transactions.
SAVEPOINTS	Whether or not savepoints are supported.

It provides identical information to the SHOW ENGINES statement. Since storage engines are plugins, different information about them is also shown in the information_schema.PLUGINS table and by the SHOW PLUGINS statement.

The table is not a standard Information Schema table, and is a MySQL and MariaDB extension.

Note that both MySQL's InnoDB and Percona's XtraDB replacement are labeled as `InnoDB`. However, if XtraDB is in use, it will be specified in the `COMMENT` field. See XtraDB and InnoDB. The same applies to FederatedX.

Example

```
SELECT * FROM information_schema.ENGINES\G;
*************************** 1. row ***************************
      ENGINE: InnoDB
     SUPPORT: DEFAULT
     COMMENT: Supports transactions, row-level locking, and foreign keys
TRANSACTIONS: YES
          XA: YES
  SAVEPOINTS: YES
*************************** 2. row ***************************
      ENGINE: CSV
     SUPPORT: YES
     COMMENT: CSV storage engine
TRANSACTIONS: NO
          XA: NO
  SAVEPOINTS: NO
*************************** 3. row ***************************
      ENGINE: MyISAM
     SUPPORT: YES
     COMMENT: MyISAM storage engine
TRANSACTIONS: NO
          XA: NO
  SAVEPOINTS: NO
*************************** 4. row ***************************
      ENGINE: BLACKHOLE
     SUPPORT: YES
     COMMENT: /dev/null storage engine (anything you write to it disappears)
TRANSACTIONS: NO
          XA: NO
  SAVEPOINTS: NO
*************************** 5. row ***************************
      ENGINE: FEDERATED
     SUPPORT: YES
     COMMENT: FederatedX pluggable storage engine
TRANSACTIONS: YES
          XA: NO
  SAVEPOINTS: YES
*************************** 6. row ***************************
      ENGINE: MRG_MyISAM
     SUPPORT: YES
     COMMENT: Collection of identical MyISAM tables
TRANSACTIONS: NO
          XA: NO
  SAVEPOINTS: NO
*************************** 7. row ***************************
      ENGINE: ARCHIVE
     SUPPORT: YES
     COMMENT: Archive storage engine
TRANSACTIONS: NO
          XA: NO
  SAVEPOINTS: NO
*************************** 8. row ***************************
      ENGINE: MEMORY
     SUPPORT: YES
     COMMENT: Hash based, stored in memory, useful for temporary tables
TRANSACTIONS: NO
          XA: NO
  SAVEPOINTS: NO
*************************** 9. row ***************************
      ENGINE: PERFORMANCE_SCHEMA
     SUPPORT: YES
     COMMENT: Performance Schema
TRANSACTIONS: NO
          XA: NO
  SAVEPOINTS: NO
*************************** 10. row ***************************
      ENGINE: Aria
     SUPPORT: YES
```

```
     COMMENT: Crash-safe tables with MyISAM heritage
TRANSACTIONS: NO
          XA: NO
  SAVEPOINTS: NO
10 rows in set (0.00 sec)
```

Check which storage engine supports XA transactions:

```
SELECT ENGINE FROM information_schema.ENGINES WHERE XA = 'YES';
+--------+
| ENGINE |
+--------+
| InnoDB |
+--------+
```

This page is licensed: CC BY-SA / Gnu FDL

Information Schema EVENTS Table

The Information Schema `EVENTS` table stores information about Events on the server.

It contains the following columns:

Column	Description
EVENT_CATALOG	Always def.
EVENT_SCHEMA	Database where the event was defined.
EVENT_NAME	Event name.
DEFINER	Event definer.
TIME_ZONE	Time zone used for the event's scheduling and execution, by default SYSTEM.
EVENT_BODY	SQL.
EVENT_DEFINITION	The SQL defining the event.
EVENT_TYPE	Either ONE TIME or RECURRING.
EXECUTE_AT	DATETIME when the event is set to execute, or NULL if recurring.
INTERVAL_VALUE	Numeric interval between event executions for a recurring event, or NULL if not recurring.
INTERVAL_FIELD	Interval unit (e.g., HOUR)
SQL_MODE	The SQL_MODE at the time the event was created.
STARTS	Start DATETIME for a recurring event, NULL if not defined or not recurring.
ENDS	End DATETIME for a recurring event, NULL if not defined or not recurring.
STATUS	One of ENABLED, DISABLED or /SLAVESIDE_DISABLED.
ON_COMPLETION	The ON COMPLETION clause, either PRESERVE or NOT PRESERVE .
CREATED	When the event was created.
LAST_ALTERED	When the event was last changed.
LAST_EXECUTED	When the event was last run.
EVENT_COMMENT	The comment provided in the CREATE EVENT statement, or an empty string if none.
ORIGINATOR	MariaDB server ID on which the event was created.
CHARACTER_SET_CLIENT	character_set_client system variable session value at the time the event was created.
COLLATION_CONNECTION	collation_connection system variable session value at the time the event was created.
DATABASE_COLLATION	Database collation with which the event is linked.

The SHOW EVENTS and SHOW CREATE EVENT statements provide similar information.

This page is licensed: CC BY-SA / Gnu FDL

Information Schema FEEDBACK Table

The Information Schema `FEEDBACK` table is created when the Feedback Plugin is enabled, and contains the complete contents submitted by the plugin.

It contains two columns:

Column	Description
VARIABLE_NAME	Name of the item of information being collected.
VARIABLE_VALUE	Contents of the item of information being collected.

It is possible to disable automatic collection, by setting the feedback_url variable to an empty string, and to submit the contents manually, as follows:

```
$ mysql -e 'SELECT * FROM information_schema.FEEDBACK' > report.txt
```

Then you can send it by opening post in your browser, and uploading your generated `report.txt`. Or you can do it from the command line with (for example):

```
$ curl -F data=@report.txt https://mariadb.org/feedback_plugin/post
```

Manual uploading allows you to be absolutely sure that we receive only the data shown in the `information_schema.FEEDBACK` table and that no private or sensitive information is being sent.

Example

```
SELECT * FROM information_schema.FEEDBACK\G
...
*************************** 906. row ***************************
 VARIABLE_NAME: Uname_sysname
VARIABLE_VALUE: Linux
*************************** 907. row ***************************
 VARIABLE_NAME: Uname_release
VARIABLE_VALUE: 3.13.0-53-generic
*************************** 908. row ***************************
 VARIABLE_NAME: Uname_version
VARIABLE_VALUE: #89-Ubuntu SMP Wed May 20 10:34:39 UTC 2015
*************************** 909. row ***************************
 VARIABLE_NAME: Uname_machine
VARIABLE_VALUE: x86_64
*************************** 910. row ***************************
 VARIABLE_NAME: Uname_distribution
VARIABLE_VALUE: lsb: Ubuntu 14.04.2 LTS
*************************** 911. row ***************************
 VARIABLE_NAME: Collation used latin1_german1_ci
VARIABLE_VALUE: 1
*************************** 912. row ***************************
 VARIABLE_NAME: Collation used latin1_swedish_ci
VARIABLE_VALUE: 18
*************************** 913. row ***************************
 VARIABLE_NAME: Collation used utf8_general_ci
VARIABLE_VALUE: 567
*************************** 914. row ***************************
 VARIABLE_NAME: Collation used latin1_bin
VARIABLE_VALUE: 1
*************************** 915. row ***************************
 VARIABLE_NAME: Collation used binary
VARIABLE_VALUE: 16
*************************** 916. row ***************************
 VARIABLE_NAME: Collation used utf8_bin
VARIABLE_VALUE: 4044
```

Information Schema FILE_KEY_MANAGEMENT_KEYS Table

> **Note:**
>
> This table is available from MariaDB Enterprise Server 11.8.

The `INFORMATION_SCHEMA.FILE_KEY_MANAGEMENT_KEYS` table lists key ID and latest key version for keys managed by the file_key_management plugin. The table's contents can be queried directly, or viewed using the `SHOW FILE_KEY_MANAGEMENT_KEYS` statement.

You can also can reload the data from the key file into the cache by issuing this statement:

```
FLUSH FILE_KEY_MANAGEMENT_KEYS
```

This functionality is provided by the `file_key_management` plugin.

This Information Schema table allows to query the key numbers and key versions which are currently in the cache (which can be different to the file). It also allows to verify which keys are in use when joining the table with INNODB_TABLESPACES_ENCRYPTION.

This page is licensed: CC BY-SA / Gnu FDL

Information Schema HASHICORP_KEY_MANAGEMENT_CACHE Table

> **Note:**
>
> This table is available from MariaDB 12.3.

The `INFORMATION_SCHEMA.HASHICORP_KEY_MANAGEMENT_CACHE` table lists the Key ID and the latest Key Version for keys managed by the HashiCorp Key Management plugin. The table's contents can be queried directly, or viewed using the `SHOW HASHICORP_KEY_MANAGEMENT_CACHE` statement.

You can reload the data from the Vault server into the cache by issuing this statement:

```
FLUSH HASHICORP_KEY_MANAGEMENT_CACHE
```

This functionality is provided by the HashiCorp Key Management plugin.

This Information Schema table allows you to query the key numbers and key versions which are currently in the cache.

Columns

The table contains the following columns:

Column Name	Description
`KEY_ID`	The Key ID used by the plugin.
`KEY_VERSION`	The latest version of the key currently in the cache.

Required Privileges

Accessing the `INFORMATION_SCHEMA.HASHICORP_KEY_MANAGEMENT_CACHE` table requires the `PROCESS` privilege.

This page is licensed: CC BY-SA / Gnu FDL

Information Schema GEOMETRY_COLUMNS Table

Description

The Information Schema `GEOMETRY_COLUMNS` table provides support for Spatial Reference systems for GIS data.

It contains the following columns:

Column	Type	Null	Description
F_TABLE_CATALOG	VARCHAR(512)	NO	Together with F_TABLE_SCHEMA and F_TABLE_NAME, the fully qualified name of the featured table containing the geometry column.
F_TABLE_SCHEMA	VARCHAR(64)	NO	Together with F_TABLE_CATALOG and F_TABLE_NAME, the fully qualified name of the featured table containing the geometry column.
F_TABLE_NAME	VARCHAR(64)	NO	Together with F_TABLE_CATALOG and F_TABLE_SCHEMA, the fully qualified name of the featured table containing the geometry column.
F_GEOMETRY_COLUMN	VARCHAR(64)	NO	Name of the column in the featured table that is the geometry golumn.
G_TABLE_CATALOG	VARCHAR(512)	NO	
G_TABLE_SCHEMA	VARCHAR(64)	NO	Database name of the table implementing the geometry column.

Column	Type	Null	Description
G_TABLE_NAME	VARCHAR(64)	NO	Table name that is implementing the geometry column.
G_GEOMETRY_COLUMN	VARCHAR(64)	NO	
STORAGE_TYPE	TINYINT(2)	NO	Binary geometry implementation. Always 1 in MariaDB.
GEOMETRY_TYPE	INT(7)	NO	Integer reflecting the type of geometry stored in this column (see table below).
COORD_DIMENSION	TINYINT(2)	NO	Number of dimensions in the spatial reference system. Always 2 in MariaDB.
MAX_PPR	TINYINT(2)	NO	Always 0 in MariaDB.
SRID	SMALLINT(5)	NO	ID of the Spatial Reference System used for the coordinate geometry in this table. It is a foreign key reference to the SPATIAL_REF_SYS table.

Storage_type

The integers in the `storage_type` field match the geometry types as follows:

Integer	Type
0	GEOMETRY
1	POINT
3	LINESTRING
5	POLYGON
7	MULTIPOINT
9	MULTILINESTRING
11	MULTIPOLYGON

Example

```
CREATE TABLE g1(g GEOMETRY(9,4) REF_SYSTEM_ID=101);

SELECT * FROM information_schema.GEOMETRY_COLUMNS\G
*************************** 1. row ***************************
  F_TABLE_CATALOG: def
   F_TABLE_SCHEMA: test
     F_TABLE_NAME: g1
F_GEOMETRY_COLUMN:
  G_TABLE_CATALOG: def
   G_TABLE_SCHEMA: test
     G_TABLE_NAME: g1
G_GEOMETRY_COLUMN: g
     STORAGE_TYPE: 1
    GEOMETRY_TYPE: 0
  COORD_DIMENSION: 2
          MAX_PPR: 0
             SRID: 101
```

See also

- The SPATIAL_REF_SYS table.

This page is licensed: CC BY-SA / Gnu FDL

Information Schema GLOBAL_STATUS and SESSION_STATUS Tables

The Information Schema `GLOBAL_STATUS` and `SESSION_STATUS` tables store a record of all status variables and their global and session values respectively. This is the same information as displayed by the SHOW STATUS commands `SHOW GLOBAL STATUS` and `SHOW SESSION STATUS`.

They contain the following columns:

Column	Description
VARIABLE_NAME	Status variable name.
VARIABLE_VALUE	Global or session value.

Example

```
SELECT * FROM information_schema.GLOBAL_STATUS;
+-----------------------------------------------+--------------------+
| VARIABLE_NAME                                 | VARIABLE_VALUE     |
+-----------------------------------------------+--------------------+
...
| BINLOG_SNAPSHOT_FILE                          | mariadb-bin.000208 |
| BINLOG_SNAPSHOT_POSITION                      | 369                |
...
| THREADS_CONNECTED                             | 1                  |

Information Schema GLOBAL_VARIABLES and SESSION_VARIABLES Tables

The Information Schema `GLOBAL_VARIABLES` and `SESSION_VARIABLES` tables stores a record of all system variables and their global and session values respectively. This is the same information as displayed by the SHOW VARIABLES commands `SHOW GLOBAL VARIABLES` and `SHOW SESSION VARIABLES`.

It contains the following columns:

Column	Description
VARIABLE_NAME	System variable name.
VARIABLE_VALUE	Global or session value.

Example

```
SELECT * FROM information_schema.GLOBAL_VARIABLES ORDER BY VARIABLE_NAME\G
*************************** 1. row ***************************
 VARIABLE_NAME: ARIA_BLOCK_SIZE
VARIABLE_VALUE: 8192
*************************** 2. row ***************************
 VARIABLE_NAME: ARIA_CHECKPOINT_LOG_ACTIVITY
VARIABLE_VALUE: 1048576
*************************** 3. row ***************************
 VARIABLE_NAME: ARIA_CHECKPOINT_INTERVAL
VARIABLE_VALUE: 30
...
*************************** 455. row ***************************
 VARIABLE_NAME: VERSION_COMPILE_MACHINE
VARIABLE_VALUE: x86_64
*************************** 456. row ***************************
 VARIABLE_NAME: VERSION_COMPILE_OS
VARIABLE_VALUE: debian-linux-gnu
*************************** 457. row ***************************
 VARIABLE_NAME: WAIT_TIMEOUT
VARIABLE_VALUE: 600
```

Information Schema INDEX_STATISTICS Table

The Information Schema `INDEX_STATISTICS` table shows statistics on index usage and makes it possible to do such things as locating unused indexes and generating the commands to remove them.

This is part of the User Statistics feature, which is not enabled by default.

It contains the following columns:

Field	Type	Notes
TABLE_SCHEMA	VARCHAR(192)	The schema (database) name.
TABLE_NAME	VARCHAR(192)	The table name.
INDEX_NAME	VARCHAR(192)	The index name (as visible in SHOW CREATE TABLE).
ROWS_READ	BIGINT(21)	The number of rows read from this index.
QUERIES	BIGINT(21)	Incremented for each index the query is part of. This assists one to see how effective the index is. From MariaDB 11.5

Example

```
SELECT * FROM information_schema.INDEX_STATISTICS
WHERE TABLE_NAME = "author";
+--------------+------------+------------+-----------+
| TABLE_SCHEMA | TABLE_NAME | INDEX_NAME | ROWS_READ |
+--------------+------------+------------+-----------+
| books        | author     | by_name    |        15 |
+--------------+------------+------------+-----------+
```

Information Schema KEY_CACHES Table

The Information Schema `KEY_CACHES` table shows statistics about the segmented key cache.

It contains the following columns:

Column Name	Description
KEY_CACHE_NAME	The name of the key cache
SEGMENTS	total number of segments (set to NULL for regular key caches)
SEGMENT_NUMBER	segment number (set to NULL for any regular key caches and for rows containing aggregation statistics for segmented key caches)
FULL_SIZE	memory for cache buffers/auxiliary structures
BLOCK_SIZE	size of the blocks
USED_BLOCKS	number of currently used blocks
UNUSED_BLOCKS	number of currently unused blocks
DIRTY_BLOCKS	number of currently dirty blocks
READ_REQUESTS	number of read requests
READS	number of actual reads from files into buffers
WRITE_REQUESTS	number of write requests
WRITES	number of actual writes from buffers into files

Example

```
SELECT * FROM information_schema.KEY_CACHES \G
*********************** 1. row ***********************
KEY_CACHE_NAME: default
SEGMENTS: NULL
SEGMENT_NUMBER: NULL
     FULL_SIZE: 134217728
    BLOCK_SIZE: 1024
   USED_BLOCKS: 36
 UNUSED_BLOCKS: 107146
  DIRTY_BLOCKS: 0
 READ_REQUESTS: 40305
         READS: 21
WRITE_REQUESTS: 19239
        WRITES: 358
```

Information Schema KEY_COLUMN_USAGE Table

The Information Schema `KEY_COLUMN_USAGE` table shows which key columns have constraints.

It contains the following columns:

Column	Description
CONSTRAINT_CATALOG	Always def.
CONSTRAINT_SCHEMA	Database name of the constraint.
CONSTRAINT_NAME	Name of the constraint (PRIMARY for the primary key).
TABLE_CATALOG	Always #def.
TABLE_SCHEMA	Database name of the column constraint.
TABLE_NAME	Table name of the column constraint.
COLUMN_NAME	Column name of the constraint.

Column	Description
ORDINAL_POSITION	Position of the column within the constraint.
POSITION_IN_UNIQUE_CONSTRAINT	For foreign keys, the position in the unique constraint.
REFERENCED_TABLE_SCHEMA	For foreign keys, the referenced database name.
REFERENCED_TABLE_NAME	For foreign keys, the referenced table name.
REFERENCED_COLUMN_NAME	For foreign keys, the referenced column name.

Example

```
SELECT * FROM information_schema.KEY_COLUMN_USAGE LIMIT 1 \G
*********************** 1. row ***********************
           CONSTRAINT_CATALOG: def
            CONSTRAINT_SCHEMA: my_website
              CONSTRAINT_NAME: PRIMARY
                TABLE_CATALOG: def
                 TABLE_SCHEMA: users
                  COLUMN_NAME: user_id
             ORDINAL_POSITION: 1
POSITION_IN_UNIQUE_CONSTRAINT: NULL
      REFERENCED_TABLE_SCHEMA: NULL
        REFERENCED_TABLE_NAME: NULL
       REFERENCED_COLUMN_NAME: NULL
```

Information Schema KEY_PERIOD_USAGE Table

> **Note:**
>
> This table is available as of MariaDB 11.4.

The Information Schema `KEY_PERIOD_USAGE` table shows information about Application-Time Periods.

It contains the following columns:

Column	Description
CONSTRAINT_CATALOG	
CONSTRAINT_SCHEMA	
CONSTRAINT_NAME	
TABLE_CATALOG	
TABLE_SCHEMA	
TABLE_NAME	
PERIOD_NAME

Information Schema KEYWORDS Table

> **Note:**
>
> This table is available as of MariaDB 10.6.3.

Description

The Information Schema `KEYWORDS` table contains the list of MariaDB keywords.

It contains a single column:

Column	Description
WORD	Keyword

The table is not a standard Information Schema table, but a MariaDB extension.

Example

```
SELECT * FROM INFORMATION_SCHEMA.KEYWORDS;
+-------------------------------+
| WORD                          |
+-------------------------------+
| &&                            |
| <=                            |
| <>                            |
| !=                            |
| >=                            |
| <<                            |

Information Schema LOCALES Table

Description

The Information Schema `LOCALES` table contains a list of all compiled-in locales. It is only available if the LOCALES plugin has been installed.

It contains the following columns:

Column	Description
ID	Row ID.
NAME	Locale name, for example en_GB.
DESCRIPTION	Locale description, for example English - United Kingdom.
MAX_MONTH_NAME_LENGTH	Numeric length of the longest month in the locale
MAX_DAY_NAME_LENGTH	Numeric length of the longest day name in the locale.
DECIMAL_POINT	Decimal point character (some locales use a comma).
THOUSAND_SEP	Thousand's character separator,
ERROR_MESSAGE_LANGUAGE	Error message language.

The table is not a standard Information Schema table, and is a MariaDB extension.

The SHOW LOCALES statement returns a subset of the information.

Example

```
SELECT * FROM information_schema.LOCALES;
+-----+-------+-------------------------------------+----------------------+--------------------+------
---------+--------------+-----------------------+
| ID  | NAME  | DESCRIPTION                         | MAX_MONTH_NAME_LENGTH | MAX_DAY_NAME_LENGTH |
DECIMAL_POINT | THOUSAND_SEP | ERROR_MESSAGE_LANGUAGE |
+-----+-------+-------------------------------------+----------------------+--------------------+------
---------+--------------+-----------------------+
|   0 | en_US | English - United States             |                    9 |                  9 | .
| ,            | english                |

Information Schema METADATA_LOCK_INFO Table

The Information Schema `METADATA_LOCK_INFO` table is created by the metadata_lock_info plugin. It shows active metadata locks and user locks (the locks acquired with GET_LOCK).

Description

It has the following columns:

Column	Description
THREAD_ID	
LOCK_MODE	One of MDL_INTENTION_EXCLUSIVE, MDL_SHARED, MDL_SHARED_HIGH_PRIO, MDL_SHARED_READ, MDL_SHARED_READ_ONLY, MDL_SHARED_WRITE, MDL_SHARED_NO_WRITE, MDL_SHARED_NO_READ_WRITE, MDL_SHARED_UPGRADABLE or MDL_EXCLUSIVE.
LOCK_DURATION	One of MDL_STATEMENT, MDL_TRANSACTION or MDL_EXPLICIT
LOCK_TYPE	One of Global read lock, Schema metadata lock, Table metadata lock, Stored function metadata lock, Stored procedure metadata lock, Trigger metadata lock, Event metadata lock, Commit lock or User lock.

Column	Description
TABLE_SCHEMA	
TABLE_NAME	

LOCK_MODE Descriptions

The `LOCK_MODE` column can have the following values:

Value	Description
MDL_INTENTION_EXCLUSIVE	An intention exclusive metadata lock (IX). Used only for scoped locks. Owner of this type of lock can acquire upgradable exclusive locks on individual objects. Compatible with other IX locks, but is incompatible with scoped S and X locks. IX lock is taken in SCHEMA namespace when we intend to modify object metadata. Object may refer table, stored procedure, trigger, view/etc.
MDL_SHARED	A shared metadata lock (S). To be used in cases when we are interested in object metadata only and there is no intention to access object data (e.g. for stored routines or during preparing prepared statements). We also mis-use this type of lock for open HANDLERs, since lock acquired by this statement has to be compatible with lock acquired by LOCK TABLES … WRITE statement, i.e. SNRW (We can't get by acquiring S lock at HANDLER … OPEN time and upgrading it to SR lock for HANDLER … READ as it doesn't solve problem with need to abort DML statements which wait on table level lock while having open HANDLER in the same connection). To avoid deadlock which may occur when SNRW lock is being upgraded to X lock for table on which there is an active S lock which is owned by thread which waits in its turn for table-level lock owned by thread performing upgrade we have to use thr_abort_locks_for_thread() facility in such situation. This problem does not arise for locks on stored routines as we don't use SNRW locks for them. It also does not arise when S locks are used during PREPARE calls as table-level locks are not acquired in this case. This lock is taken for global read lock, when caching a stored procedure in memory for the duration of the transaction and for tables used by prepared statements.
MDL_SHARED_HIGH_PRIO	A high priority shared metadata lock. Used for cases when there is no intention to access object data (i.e. data in the table). "High priority" means that, unlike other shared locks, it is granted ignoring pending requests for exclusive locks. Intended for use in cases when we only need to access metadata and not data, e.g. when filling an INFORMATION_SCHEMA table. Since SH lock is compatible with SNRW lock, the connection that holds SH lock should not try to acquire any kind of table-level or row-level lock, as this can lead to a deadlock. Moreover, after acquiring SH lock, the connection should not wait for any other resource, as it might cause starvation for X locks and a potential deadlock during upgrade of SNW or SNRW to X lock (e.g. if the upgrading connection holds the resource that is being waited for).
MDL_SHARED_READ	A shared metadata lock (SR) for cases when there is an intention to read data from table. A connection holding this kind of lock can read table metadata and read table data (after acquiring appropriate table and row-level locks). This means that one can only acquire TL_READ, TL_READ_NO_INSERT, and similar table-level locks on table if one holds SR MDL lock on it. To be used for tables in SELECTs, subqueries, and LOCK TABLE … READ statements.
MDL_SHARED_WRITE	A shared metadata lock (SW) for cases when there is an intention to modify (and not just read) data in the table. A connection holding SW lock can read table metadata and modify or read table data (after acquiring appropriate table and row-level locks). To be used for tables to be modified by INSERT, UPDATE, DELETE statements, but not LOCK TABLE … WRITE or DDL). Also taken by SELECT … FOR UPDATE.
MDL_SHARED_UPGRADABLE	An upgradable shared metadata lock for cases when there is an intention to modify (and not just read) data in the table. Can be upgraded to MDL_SHARED_NO_WRITE and MDL_EXCLUSIVE. A connection holding SU lock can read table metadata and modify or read table data (after acquiring appropriate table and row-level locks). To be used for the first phase of ALTER TABLE.

Value	Description
MDL_SHARED_READ_ONLY	A shared metadata lock for cases when we need to read data from table and block all concurrent modifications to it (for both data and metadata). Used by LOCK TABLES READ statement.
MDL_SHARED_NO_WRITE	An upgradable shared metadata lock which blocks all attempts to update table data, allowing reads. A connection holding this kind of lock can read table metadata and read table data. Can be upgraded to X metadata lock. Note, that since this type of lock is not compatible with SNRW or SW lock types, acquiring appropriate engine-level locks for reading (TL_READ* for MyISAM, shared row locks in InnoDB) should be contention-free. To be used for the first phase of ALTER TABLE, when copying data between tables, to allow concurrent SELECTs from the table, but not UPDATEs.
MDL_SHARED_NO_READ_WRITE	An upgradable shared metadata lock which allows other connections to access table metadata, but not data. It blocks all attempts to read or update table data, while allowing INFORMATION_SCHEMA and SHOW queries. A connection holding this kind of lock can read table metadata modify and read table data. Can be upgraded to X metadata lock. To be used for LOCK TABLES WRITE statement. Not compatible with any other lock type except S and SH.
MDL_EXCLUSIVE	An exclusive metadata lock (X). A connection holding this lock can modify both table's metadata and data. No other type of metadata lock can be granted while this lock is held. To be used for CREATE/DROP/RENAME TABLE statements and for execution of certain phases of other DDL statements.

Examples

First, install the `metadata _lock_info` plugin, if it is not already installed:

```
INSTALL plugin if not exists METADATA_LOCK_INFO soname "metadata_lock_info.so";
```

User lock:

```
SELECT GET_LOCK('abc',1000);
+----------------------+
| GET_LOCK('abc',1000) |
+----------------------+
|                    1 |
+----------------------+

SELECT * FROM information_schema.METADATA_LOCK_INFO;
+-----------+--------------------------+---------------+-----------+--------------+------------+
| THREAD_ID | LOCK_MODE                | LOCK_DURATION | LOCK_TYPE | TABLE_SCHEMA | TABLE_NAME |
+-----------+--------------------------+---------------+-----------+--------------+------------+
|        61 | MDL_SHARED_NO_READ_WRITE | MDL_EXPLICIT  | User lock | abc          |            |
+-----------+--------------------------+---------------+-----------+--------------+------------+
```

Table metadata lock:

```
START TRANSACTION;

INSERT INTO t VALUES (1,2);

SELECT * FROM information_schema.METADATA_LOCK_INFO \G
*************************** 1. row ***************************
    THREAD_ID: 4
    LOCK_MODE: MDL_SHARED_WRITE
LOCK_DURATION: MDL_TRANSACTION
    LOCK_TYPE: Table metadata lock
 TABLE_SCHEMA: test
   TABLE_NAME: t
```

```
SELECT * FROM information_schema.METADATA_LOCK_INFO;
+-----------+---------------------------+--------------+---------------------+-----------------+--------
-----+
| THREAD_ID | LOCK_MODE | LOCK_DURATION | LOCK_TYPE | TABLE_SCHEMA | TABLE_NAME |
+-----------+---------------------------+--------------+---------------------+-----------------+--------
-----+
| 31 | MDL_INTENTION_EXCLUSIVE | MDL_EXPLICIT | Global read lock | | |
| 31 | MDL_INTENTION_EXCLUSIVE | MDL_EXPLICIT | Commit lock | | |
| 31 | MDL_INTENTION_EXCLUSIVE | MDL_EXPLICIT | Schema metadata lock | dbname | |
| 31 | MDL_SHARED_NO_READ_WRITE | MDL_EXPLICIT | Table metadata lock | dbname | exotics |
+-----------+---------------------------+--------------+---------------------+-----------------+--------
-----+
```

Information Schema MROONGA_STATS Table

The Information Schema `MROONGA_STATS` table only exists if the Mroonga storage engine is installed, and contains information about its activities.

Column	Description
VERSION	Mroonga version.
rows_written	Number of rows written into Mroonga tables.
rows_read	Number of rows read from all Mroonga tables.

This table always contains 1 row.

This page is licensed: CC BY-SA / Gnu FDL

Information Schema OPTIMIZER_TRACE Table

Description

The Information Schema `OPTIMIZER_TRACE` table contains Optimizer Trace information.

It contains the following columns:

Column	Description
QUERY	Displays the query that was asked to be traced.
TRACE	A JSON document displaying the stats we collected when the query was run.

Column	Description
MISSING_BYTES_BEYOND_MAX_MEM_SIZE	For huge trace, where the trace is truncated due to the optimizer_trace_max_mem_size limit being reached, displays the bytes that are missing in the trace
INSUFFICIENT_PRIVILEGES	Set to 1 if the user running the trace does not have the privileges to see the trace.

Structure:

```
SHOW CREATE TABLE INFORMATION_SCHEMA.OPTIMIZER_TRACE \G
*************************** 1. row ***************************
       Table: OPTIMIZER_TRACE
Create Table: CREATE TEMPORARY TABLE `OPTIMIZER_TRACE` (
  `QUERY` longtext NOT NULL DEFAULT '',
  `TRACE` longtext NOT NULL DEFAULT '',
  `MISSING_BYTES_BEYOND_MAX_MEM_SIZE` int(20) NOT NULL DEFAULT 0,
  `INSUFFICIENT_PRIVILEGES` tinyint(1) NOT NULL DEFAULT 0
) ENGINE=Aria DEFAULT CHARSET=utf8 PAGE_CHECKSUM=0
```

This page is licensed: CC BY-SA / Gnu FDL

Information Schema PARAMETERS Table

The Information Schema `PARAMETERS` table stores information about stored procedures and stored functions parameters.

It contains the following columns:

Column	Description
SPECIFIC_CATALOG	Always def.
SPECIFIC_SCHEMA	Database name containing the stored routine parameter.
SPECIFIC_NAME	Stored routine name.
ORDINAL_POSITION	Ordinal position of the parameter, starting at 1. 0 for a function RETURNS clause.
PARAMETER_DEFAULT	Displays default values for stored routine parameters.
PARAMETER_MODE	One of IN, OUT, INOUT or NULL for RETURNS.
PARAMETER_NAME	Name of the parameter, or NULL for RETURNS.
DATA_TYPE	The column's data type.
CHARACTER_MAXIMUM_LENGTH	Maximum length.
CHARACTER_OCTET_LENGTH	Same as the CHARACTER_MAXIMUM_LENGTH except for multi-byte character sets.
NUMERIC_PRECISION	For numeric types, the precision (number of significant digits) for the column. NULL if not a numeric field.
NUMERIC_SCALE	For numeric types, the scale (significant digits to the right of the decimal point). NULL if not a numeric field.
DATETIME_PRECISION	Fractional-seconds precision, or NULL if not a time data type.
CHARACTER_SET_NAME	Character set if a non-binary string data type, otherwise NULL.
COLLATION_NAME	Collation if a non-binary string data type, otherwise NULL.
DTD_IDENTIFIER	Description of the data type.
ROUTINE_TYPE	PROCEDURE or FUNCTION.
PARAMETER_DEFAULT	Default parameter value. From MariaDB 12.2.

Information from this table is similar to that found in the `param_list` column in the mysql.proc table, and the output of the SHOW CREATE PROCEDURE and SHOW CREATE FUNCTION statements.

To obtain information about the routine itself, you can query the Information Schema ROUTINES table.

Example

```
SELECT * FROM information_schema.PARAMETERS
LIMIT 1 \G
********************* 1. row *********************
        SPECIFIC_CATALOG: def
         SPECIFIC_SCHEMA: accounts
           SPECIFIC_NAME: user_counts
        ORDINAL_POSITION: 1
          PARAMETER_MODE: IN
          PARAMETER_NAME: user_order
               DATA_TYPE: varchar
CHARACTER_MAXIMUM_LENGTH: 255
  CHARACTER_OCTET_LENGTH: 765
       NUMERIC_PRECISION: NULL
           NUMERIC_SCALE: NULL
      DATETIME_PRECISION: NULL
      CHARACTER_SET_NAME: utf8
          COLLATION_NAME: utf8_general_ci
          DTD_IDENTIFIER: varchar(255)
            ROUTINE_TYPE: PROCEDURE
       PARAMETER_DEFAULT: NULL
```

Information Schema PARTITIONS Table

The Information Schema `PARTITIONS` contains information about table partitions, with each record corresponding to a single partition or subpartition of a partitioned table. Each non-partitioned table also has a record in the `PARTITIONS` table, but most of the values are `NULL`.

It contains the following columns:

Column	Description
TABLE_CATALOG	Always def.
TABLE_SCHEMA	Database name.
TABLE_NAME	Table name containing the partition.
PARTITION_NAME	Partition name.
SUBPARTITION_NAME	Subpartition name, or NULL if not a subpartition.
PARTITION_ORDINAL_POSITION	Order of the partition starting from 1.
SUBPARTITION_ORDINAL_POSITION	Order of the subpartition starting from 1.
PARTITION_METHOD	The partitioning type; one of RANGE, LIST, HASH, LINEAR HASH, KEY or LINEAR KEY.
SUBPARTITION_METHOD	Subpartition type; one of HASH, LINEAR HASH, KEY or LINEAR KEY, or NULL if not a subpartition.

Column	Description
PARTITION_EXPRESSION	Expression used to create the partition by the CREATE TABLE or ALTER TABLE statement.
SUBPARTITION_EXPRESSION	Expression used to create the subpartition by the CREATE TABLE or ALTER TABLE statement, or NULL if not a subpartition.
PARTITION_DESCRIPTION	For a RANGE partition, contains either MAXINTEGER or an integer, as set in the VALUES LESS THAN clause. For a LIST partition, contains a comma-separated list of integers, as set in the VALUES IN. For a SYSTEM_TIME INTERVAL partition, shows a defined upper boundary timestamp for historical values (the last history partition can contain values above the upper boundary). NULL if another type of partition.
TABLE_ROWS	Number of rows in the table (may be an estimate for some storage engines).
AVG_ROW_LENGTH	Average row length, that is DATA_LENGTH divided by TABLE_ROWS
DATA_LENGTH	Total number of bytes stored in all rows of the partition.
MAX_DATA_LENGTH	Maximum bytes that could be stored in the partition.
INDEX_LENGTH	Size in bytes of the partition index file.
DATA_FREE	Unused bytes allocated to the partition.
CREATE_TIME	Time the partition was created
UPDATE_TIME	Time the partition was last modified.
CHECK_TIME	Time the partition was last checked, or NULL for storage engines that don't record this information.
CHECKSUM	Checksum value, or NULL if none.
PARTITION_COMMENT	Partition comment, truncated to 80 characters, or an empty string if no comment.
NODEGROUP	Node group, only used for MySQL Cluster, defaults to 0.
TABLESPACE_NAME	Always default.

This page is licensed: CC BY-SA / Gnu FDL

Information Schema PERIODS Table

> **Note:**
>
> This table is available as of MariaDB 11.4.

The Information Schema `PERIODS` table provides information about Application-Time Periods.

It contains the following columns:

Column	Description
TABLE_CATALOG	Always contains the string 'def'.
TABLE_SCHEMA	Database name.

Column	Description
TABLE_NAME	Table name.
PERIOD	Period name.
START_COLUMN_NAME	Name of the column that starts the period.
END_COLUMN_NAME	Name of the column that ends the period.

Example

```
CREATE OR REPLACE TABLE t1(
 name VARCHAR(50),
 date_1 DATE,
 date_2 DATE,
 PERIOD FOR date_period(date_1, date_2)
);

SELECT * FROM INFORMATION_SCHEMA.PERIODS;
+---------------+--------------+------------+-------------+-------------------+-----------------+
| TABLE_CATALOG | TABLE_SCHEMA | TABLE_NAME | PERIOD      | START_COLUMN_NAME | END_COLUMN_NAME |
+---------------+--------------+------------+-------------+-------------------+-----------------+
| def           | test         | t1         | date_period | date_1            | date_2          |
+---------------+--------------+------------+-------------+-------------------+-----------------+
```

This page is licensed: CC BY-SA / Gnu FDL

Information Schema PLUGINS Table

The Information Schema `PLUGINS` table contains information about server plugins.

It contains the following columns:

Column	Description
PLUGIN_NAME	Name of the plugin.
PLUGIN_VERSION	Version from the plugin's general type descriptor.
PLUGIN_STATUS	Plugin status, one of ACTIVE, INACTIVE, DISABLED or DELETED.
PLUGIN_TYPE	Plugin type; STORAGE ENGINE, INFORMATION_SCHEMA, AUTHENTICATION, REPLICATION, DAEMON or AUDIT.
PLUGIN_TYPE_VERSION	Version from the plugin's type-specific descriptor.
PLUGIN_LIBRARY	Plugin's shared object file name, located in the directory specified by the plugin_dir system variable, and used by the INSTALL PLUGIN and UNINSTALL PLUGIN statements. NULL if the plugin is complied in and cannot be uninstalled.
PLUGIN_LIBRARY_VERSION	Version from the plugin's API interface.
PLUGIN_AUTHOR	Author of the plugin.
PLUGIN_DESCRIPTION	Description.
PLUGIN_LICENSE	Plugin's licence.
LOAD_OPTION	How the plugin was loaded; one of OFF, ON, FORCE or FORCE_PLUS_PERMANENT. See Installing Plugins.
PLUGIN_MATURITY	Plugin's maturity level; one of Unknown, Experimental, Alpha, Beta,'Gamma, and Stable.

Column	Description
PLUGIN_AUTH_VERSION	Plugin's version as determined by the plugin author. An example would be '0.99 beta 1'.

It provides a superset of the information shown by the SHOW PLUGINS statement. For specific information about storage engines (a particular type of plugins), see the information_schema.ENGINES table and the SHOW ENGINES statement.

This table provides a subset of the Information Schema information_schema.ALL_PLUGINS table, which contains all available plugins, installed or not.

The table is not a standard Information Schema table, and is a MariaDB extension.

Examples

The easiest way to get basic information on plugins is with SHOW PLUGINS:

```
SHOW PLUGINS;

+----------------------------+----------+--------------------+-------------+---------+
| Name                       | Status   | Type               | Library     | License |
+----------------------------+----------+--------------------+-------------+---------+
| binlog                     | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| mysql_native_password      | ACTIVE   | AUTHENTICATION     | NULL        | GPL     |
| mysql_old_password         | ACTIVE   | AUTHENTICATION     | NULL        | GPL     |
| MRG_MyISAM                 | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| MyISAM                     | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| CSV                        | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| MEMORY                     | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| FEDERATED                  | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| PERFORMANCE_SCHEMA         | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| Aria                       | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| InnoDB                     | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| INNODB_TRX                 | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_LOCKS               | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_LOCK_WAITS          | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_CMP                 | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_CMP_RESET           | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_CMPMEM              | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_CMPMEM_RESET        | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_BUFFER_PAGE         | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_BUFFER_PAGE_LRU     | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_BUFFER_POOL_STATS   | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_METRICS             | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_FT_DEFAULT_STOPWORD | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_FT_INSERTED         | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_FT_DELETED          | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_FT_BEING_DELETED    | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_FT_CONFIG           | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_FT_INDEX_CACHE      | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_FT_INDEX_TABLE      | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_SYS_TABLES          | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_SYS_TABLESTATS      | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_SYS_INDEXES         | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_SYS_COLUMNS         | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_SYS_FIELDS          | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_SYS_FOREIGN         | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_SYS_FOREIGN_COLS    | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| SPHINX                     | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| ARCHIVE                    | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| BLACKHOLE                  | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| FEEDBACK                   | DISABLED | INFORMATION SCHEMA | NULL        | GPL     |
| partition                  | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| pam                        | ACTIVE   | AUTHENTICATION     | auth_pam.so | GPL     |
+----------------------------+----------+--------------------+-------------+---------+
```

The equivalent SELECT query would be:

```
SELECT PLUGIN_NAME, PLUGIN_STATUS,
PLUGIN_TYPE, PLUGIN_LIBRARY, PLUGIN_LICENSE
FROM INFORMATION_SCHEMA.PLUGINS;
```

Other SELECT queries can be used to see additional information. For example:

```
SELECT PLUGIN_NAME, PLUGIN_DESCRIPTION,
PLUGIN_MATURITY, PLUGIN_AUTH_VERSION
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_TYPE='STORAGE ENGINE'
ORDER BY PLUGIN_MATURITY \G

Information Schema PROCESSLIST Table

The Information Schema `PROCESSLIST` table contains information about running threads.

Similar information can also be returned with the SHOW [FULL] PROCESSLIST statement, or the mariadb-admin processlist command.

It contains the following columns:

Column	Description
ID	Connection identifier.
USER	MariaDB User.
HOST	The hostname from which this client is connected.For Unix socket connections, this is `localhost`. For TCP/IP connections, the TCP port is appended (for instance, `192.168.1.17:58061` or `other-host.company.com:58061`). For the system user, this column is blank (`''`).
DB	Default database, or `NULL` if none.
COMMAND	Type of command running, corresponding to the Com_ status variables. See Thread Command Values.
TIME	Seconds that the thread has spent on the current `COMMAND` so far.
STATE	Current state of the thread. See Thread States.
INFO	Statement the thread is executing, or `NULL` if none.
TIME_MS	Time in milliseconds with microsecond precision that the thread has spent on the current `COMMAND` so far (see more).
STAGE	The stage the process is currently in.
MAX_STAGE	The maximum number of stages.
PROGRESS	The progress of the process within the current stage (0-100%).
MEMORY_USED	Memory in bytes used by the thread.

Column	Description
MAX_MEMORY_USED	Maximum memory in bytes used by the thread.
EXAMINED_ROWS	Rows examined by the thread. Only updated by `UPDATE`, `DELETE`, and similar statements. For `SELECT` and other statements, the value remains zero.
SENT_ROWS	Number of rows sent by the statement being executed. From MariaDB 11.3.0.
QUERY_ID	Query ID.
INFO_BINARY	Binary data information
TID	Thread ID (MDEV-6756)
TMP_SPACE_USED	See Limiting Size of Created Disk Temporary Files and Tables Overview. From MariaDB 11.5.

Note that as a difference to MySQL, in MariaDB the `TIME` column (and also the `TIME_MS` column) are not affected by any setting of @TIMESTAMP. This means that it can be reliably used also for threads that change `@TIMESTAMP` (such as the replication SQL thread). See also MySQL Bug #22047.

As a consequence of this, the `TIME` column of `SHOW FULL PROCESSLIST` and `INFORMATION_SCHEMA.PROCESSLIST` cannot be used to determine if a slave is lagging behind. For this, use instead the `Seconds_Behind_Master` column in the output of SHOW REPLICA STATUS.

Note that the `PROGRESS` field from the information schema, and the `PROGRESS` field from `SHOW PROCESSLIST` display different results. `SHOW PROCESSLIST` shows the total progress, while the information schema shows the progress for the current stage only. To retrieve a similar “total” Progress value from `information_schema.PROCESSLIST` as the one from `SHOW PROCESSLIST`, issue this statement:

```
SELECT CASE WHEN Max_Stage < 2 THEN Progress ELSE (Stage-1)/Max_Stage*100+Progress/Max_Stage END
  AS Progress FROM INFORMATION_SCHEMA.PROCESSLIST;
```

Example

```
SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST\G
*************************** 1. row ***************************
           ID: 9
         USER: msandbox
         HOST: localhost
           DB: NULL
      COMMAND: Query
         TIME: 0
        STATE: Filling schema table
         INFO: SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST
      TIME_MS: 0.351
        STAGE: 0
    MAX_STAGE: 0
     PROGRESS: 0.000
  MEMORY_USED: 85392
EXAMINED_ROWS: 0
     QUERY_ID: 15
  INFO_BINARY: SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST
          TID: 11838
*************************** 2. row ***************************
           ID: 5
         USER: system user
         HOST:
           DB: NULL
      COMMAND: Daemon
         TIME: 0
        STATE: InnoDB shutdown handler
         INFO: NULL
      TIME_MS: 0.000
        STAGE: 0
    MAX_STAGE: 0
     PROGRESS: 0.000
  MEMORY_USED: 24160
EXAMINED_ROWS: 0
     QUERY_ID: 0
  INFO_BINARY: NULL
          TID: 3856
...
```

Information Schema PROFILING Table

The Information Schema `PROFILING` table contains information about statement resource usage. Profiling information is only recorded if the profiling session variable is set to `1`.

It contains the following columns:

Column Name	Description
QUERY_ID	Query_ID.
SEQ	Sequence number showing the display order for rows with the same QUERY_ID.
STATE	Profiling state.
DURATION	Time in seconds that the statement has been in the current state.
CPU_USER	User CPU usage in seconds.
CPU_SYSTEM	System CPU usage in seconds.
CONTEXT_VOLUNTARY	Number of voluntary context switches.

Column Name	Description
CONTEXT_INVOLUNTARY	Number of involuntary context switches.
BLOCK_OPS_IN	Number of block input operations.
BLOCK_OPS_OUT	Number of block output operations.
MESSAGES_SENT	Number of communications sent.
MESSAGES_RECEIVED	Number of communications received.
PAGE_FAULTS_MAJOR	Number of major page faults.
PAGE_FAULTS_MINOR	Number of minor page faults.
SWAPS	Number of swaps.
SOURCE_FUNCTION	Function in the source code executed by the profiled state.
SOURCE_FILE	File in the source code executed by the profiled state.
SOURCE_LINE	Line in the source code executed by the profiled state.

It contains similar information to the SHOW PROFILE and SHOW PROFILES statements.

Profiling is enabled per session. When a session ends, its profiling information is lost.

Information Schema QUERY_CACHE_INFO Table

Description

> **Note:**
>
> This table is not a standard Information Schema table, but a MariaDB extension.

The `QUERY_CACHE_INFO` table is created by the QUERY_CACHE_INFO plugin, and allows you to see the contents of the query cache. It creates a table in the information_schema database that shows all queries that are in the cache. You must have the `PROCESS` privilege (see GRANT) to use this table.

It contains the following columns:

Column	Description
STATEMENT_SCHEMA	Database used when query was included
STATEMENT_TEXT	Query text
RESULT_BLOCKS_COUNT	Number of result blocks
RESULT_BLOCKS_SIZE	Size in bytes of result blocks
RESULT_BLOCKS_SIZE_USED	Size in bytes of used blocks
LIMIT	
MAX_SORT_LENGTH	
GROUP_CONCAT_MAX_LENGTH	
CHARACTER_SET_CLIENT	
CHARACTER_SET_RESULT	
COLLATION	
TIMEZONE	
DEFAULT_WEEK_FORMAT	

Column	Description
DIV_PRECISION_INCREMENT	
SQL_MODE	
LC_TIME_NAMES	
CLIENT_LONG_FLAG	
CLIENT_PROTOCOL_41	
PROTOCOL_TYPE	
MORE_RESULTS_EXISTS	
IN_TRANS	
AUTOCOMMIT	
PACKET_NUMBER	
HITS	Incremented each time the query cache is hit.

For example:

```
SELECT * FROM information_schema.QUERY_CACHE_INFO;
+------------------+-----------------+---------------------+-------------------+-----------------------
-+
| STATEMENT_SCHEMA | STATEMENT_TEXT  | RESULT_BLOCKS_COUNT | RESULT_BLOCKS_SIZE | RESULT_BLOCKS_SIZE_USED
|
+------------------+-----------------+---------------------+-------------------+-----------------------
-+
...
| test             | SELECT * FROM a |                   1 |               512 |                    143
|
| test             | select * FROM a |                   1 |               512 |                    143
|
...
+------------------+-----------------+---------------------+-------------------+-----------------------
-
```

Information Schema QUERY_RESPONSE_TIME Table

Description

The Information Schema `QUERY_RESPONSE_TIME` table contains information about queries that take a long time to execute . It is only available if the QUERY_RESPONSE_TIME plugin has been installed.

It contains the following columns:

Column	Description
TIME	Time interval
COUNT	Count of queries falling into the time interval
TOTAL	Total execution time of all queries for this interval

See QUERY_RESPONSE_TIME plugin for a full description.

The table is not a standard Information Schema table, and is a MariaDB extension.

SHOW QUERY_RESPONSE_TIME is available as an alternative for retrieving the data.

Example

```
SELECT * FROM information_schema.QUERY_RESPONSE_TIME;
+----------------+-------+----------------+
| TIME           | COUNT | TOTAL          |
+----------------+-------+----------------+
|       0.000001 |     0 |       0.000000 |
|       0.000010 |    17 |       0.000094 |
|       0.000100 |  4301 |       0.236555 |
|       0.001000 |  1499 |       0.824450 |
|       0.010000 | 14851 |      81.680502 |
|       0.100000 |  8066 |     443.635693 |
|       1.000000 |     0 |       0.000000 |
|      10.000000 |     0 |       0.000000 |
|     100.000000 |     1 |      55.937094 |
|    1000.000000 |     0 |       0.000000 |
|   10000.000000 |     0 |       0.000000 |
|  100000.000000 |     0 |       0.000000 |
| 1000000.000000 |     0 |       0.000000 |
| TOO LONG       |     0 | TOO LONG       |
+----------------+-------+----------------+
```

Information Schema REFERENTIAL_CONSTRAINTS Table

The Information Schema `REFERENTIAL_CONSTRAINTS` table contains information about foreign keys. The single columns are listed in the KEY_COLUMN_USAGE table.

It has the following columns:

Column	Description
CONSTRAINT_CATALOG	Always def.
CONSTRAINT_SCHEMA	Database name, together with CONSTRAINT_NAME identifies the foreign key.
CONSTRAINT_NAME	Foreign key name, together with CONSTRAINT_SCHEMA identifies the foreign key.
UNIQUE_CONSTRAINT_CATALOG	Always def.
UNIQUE_CONSTRAINT_SCHEMA	Database name, together with UNIQUE_CONSTRAINT_NAME and REFERENCED_TABLE_NAME identifies the referenced key.
UNIQUE_CONSTRAINT_NAME	Referenced key name, together with UNIQUE_CONSTRAINT_SCHEMA and REFERENCED_TABLE_NAME identifies the referenced key.
MATCH_OPTION	Always NONE.
UPDATE_RULE	The Update Rule; one of CASCADE, SET NULL, SET DEFAULT, RESTRICT, NO ACTION.
DELETE_RULE	The Delete Rule; one of CASCADE, SET NULL, SET DEFAULT, RESTRICT, NO ACTION.
TABLE_NAME	Table name from the TABLE_CONSTRAINTS table.
REFERENCED_TABLE_NAME	Referenced key table name, together with UNIQUE_CONSTRAINT_SCHEMA and UNIQUE_CONSTRAINT_NAME identifies the referenced key.

This page is licensed: CC BY-SA / Gnu FDL

Information Schema ROUTINES Table

The Information Schema `ROUTINES` table stores information about stored procedures and stored functions.

It contains the following columns:

Column	Description
SPECIFIC_NAME	
ROUTINE_CATALOG	Always def.
ROUTINE_SCHEMA	Database name associated with the routine.
ROUTINE_NAME	Name of the routine.
ROUTINE_TYPE	Whether the routine is a PROCEDURE or a FUNCTION.
DATA_TYPE	The return value's data type (for stored functions).
CHARACTER_MAXIMUM_LENGTH	Maximum length.
CHARACTER_OCTET_LENGTH	Same as the CHARACTER_MAXIMUM_LENGTH except for multi-byte character sets.
NUMERIC_PRECISION	For numeric types, the precision (number of significant digits) for the column. NULL if not a numeric field.
NUMERIC_SCALE	For numeric types, the scale (significant digits to the right of the decimal point). NULL if not a numeric field.
DATETIME_PRECISION	Fractional-seconds precision, or NULL if not a time data type.
CHARACTER_SET_NAME	Character set if a non-binary string data type, otherwise NULL.
COLLATION_NAME	Collation if a non-binary string data type, otherwise NULL.
DATA_TYPE	The column's data type.
ROUTINE_BODY	Always SQL.
ROUTINE_DEFINITION	Definition of the routine.
EXTERNAL_NAME	Always NULL.
EXTERNAL_LANGUAGE	Always SQL.
PARAMETER_STYLE	Always SQL.
IS_DETERMINISTIC	Whether the routine is deterministic (can produce only one result for a given list of parameters) or not.
SQL_DATA_ACCESS	One of READS SQL DATA, MODIFIES SQL DATA, CONTAINS SQL, or NO SQL.
SQL_PATH	Always NULL.
SECURITY_TYPE	INVOKER or DEFINER. Indicates which user's privileges apply to this routine.
CREATED	Date and time the routine was created.
LAST_ALTERED	Date and time the routine was last changed.
SQL_MODE	The SQL_MODE at the time the routine was created.
ROUTINE_COMMENT	Comment associated with the routine.
DEFINER	If the SECURITY_TYPE is DEFINER, this value indicates which user defined this routine.
CHARACTER_SET_CLIENT	The character set used by the client that created the routine.
COLLATION_CONNECTION	The collation (and character set) used by the connection that created the routine.
DATABASE_COLLATION	The default collation (and character set) for the database, at the time the routine was created.

It provides information similar to, but more complete, than the SHOW PROCEDURE STATUS and SHOW FUNCTION STATUS statements.

For information about the parameters accepted by the routine, you can query the information_schema.PARAMETERS table.

Information Schema SCHEMA_PRIVILEGES Table

The Information Schema `SCHEMA_PRIVILEGES` table contains information about database privileges.

It contains the following columns:

Column	Description
GRANTEE	Account granted the privilege in the format user_name@host_name.
TABLE_CATALOG	Always def
TABLE_SCHEMA	Database name.
PRIVILEGE_TYPE	The granted privilege.
IS_GRANTABLE	Whether the privilege can be granted.

The same information in a different format can be found in the mysql.db table.

This page is licensed: CC BY-SA / Gnu FDL

Information Schema SCHEMATA Table

The Information Schema `SCHEMATA` table stores information about databases on the server.

It contains the following columns:

Column	Description
CATALOG_NAME	Always def.
SCHEMA_NAME	Database name.
DEFAULT_CHARACTER_SET_NAME	Default character set for the database.
DEFAULT_COLLATION_NAME	Default collation.
SQL_PATH	Always NULL.
SCHEMA_COMMENT	Database comment. From MariaDB 10.5.0.

Example

CURRENT

```
SELECT * FROM INFORMATION_SCHEMA.SCHEMATA\G
...
*************************** 2. row ***************************
              CATALOG_NAME: def
               SCHEMA_NAME: presentations
DEFAULT_CHARACTER_SET_NAME: latin1
    DEFAULT_COLLATION_NAME: latin1_swedish_ci
                  SQL_PATH: NULL
            SCHEMA_COMMENT: Presentations for conferences
...
```

< 10.5.0

```
SELECT * FROM INFORMATION_SCHEMA.SCHEMATA\G
*************************** 1. row ***************************
              CATALOG_NAME: def
               SCHEMA_NAME: information_schema
DEFAULT_CHARACTER_SET_NAME: utf8
    DEFAULT_COLLATION_NAME: utf8_general_ci
                  SQL_PATH: NULL
*************************** 2. row ***************************
              CATALOG_NAME: def
               SCHEMA_NAME: mysql
DEFAULT_CHARACTER_SET_NAME: latin1
    DEFAULT_COLLATION_NAME: latin1_swedish_ci
                  SQL_PATH: NULL
*************************** 3. row ***************************
              CATALOG_NAME: def
               SCHEMA_NAME: performance_schema
DEFAULT_CHARACTER_SET_NAME: utf8
    DEFAULT_COLLATION_NAME: utf8_general_ci
                  SQL_PATH: NULL
*************************** 4. row ***************************
              CATALOG_NAME: def
               SCHEMA_NAME: test
DEFAULT_CHARACTER_SET_NAME: latin1
    DEFAULT_COLLATION_NAME: latin1_swedish_ci
                  SQL_PATH: NULL
...
```

Information Schema SEQUENCES Table

> **Note:**
>
> This table is available as of MariaDB 11.5.

The Information Schema `SEQUENCES` table stores information about sequences on the server.

It contains the following columns. See CREATE SEQUENCE for details.

Column	Description
SEQUENCE_CATALOG	Catalog name
SEQUENCE_SCHEMA	Database name
SEQUENCE_NAME	Sequence name
DATA_TYPE	Data type, for example BIGINT or TINYINT UNSIGNED
NUMERIC_PRECISION	
NUMERIC_PRECISION_RADIX	
NUMERIC_SCALE	

Column	Description
START_VALUE	
MINIMUM_VALUE	
MAXIMUM_VALUE	
INCREMENT	
CYCLE_OPTION	1 if the CYCLE OPTION is set, otherwise 0

Example

```
CREATE SEQUENCE s START WITH 100 INCREMENT BY 10;

SELECT * FROM INFORMATION_SCHEMA.SEQUENCES\G
*************************** 1. row ***************************
       SEQUENCE_CATALOG: def
        SEQUENCE_SCHEMA: test
          SEQUENCE_NAME: s
              DATA_TYPE: bigint
      NUMERIC_PRECISION: 64
NUMERIC_PRECISION_RADIX: 2
          NUMERIC_SCALE: 0
            START_VALUE: 100
          MINIMUM_VALUE: 1
          MAXIMUM_VALUE: 9223372036854775806
              INCREMENT: 10
           CYCLE_OPTION: 0
```

Information Schema SLAVE_STATUS Table

> **Note:**
>
> This table is available as of MariaDB 11.6.

The Information Schema `SLAVE_STATUS` table contains replica status information, similar to SHOW REPLICA STATUS.

See SHOW REPLICA STATUS for column descriptions.

This page is licensed: CC BY-SA / Gnu FDL

Information Schema SPATIAL_REF_SYS Table

Description

The Information Schema `SPATIAL_REF_SYS` table stores information on each spatial reference system used in the database.

It contains the following columns:

Column	Type	Null	Description
SRID	smallint(5)	NO	An integer value that uniquely identifies each Spatial Reference System within a database.
AUTH_NAME	varchar(512)	NO	The name of the standard or standards body that is being cited for this reference system.
AUTH_SRID	smallint(5)	NO	The numeric ID of the coordinate system in the above authority's catalog.
SRTEXT	varchar(2048)	NO	The Well-known Text Representation of the Spatial Reference System.

Note: See MDEV-7540.

Information Schema SPIDER_ALLOC_MEM Table

The Information Schema `SPIDER_ALLOC_MEM` table is installed along with the Spider storage engine. It shows information about Spider's memory usage.

It contains the following columns:

Column	Description
ID	
FUNC_NAME	
FILE_NAME	
LINE_NO	
TOTAL_ALLOC_MEM	
CURRENT_ALLOC_MEM	
ALLOC_MEM_COUNT	
FREE_MEM_COUNT

Information Schema SQL_FUNCTIONS Table

> **Note:**
>
> This table is available as of MariaDB 10.6.3 / 10.5.12 / 10.4.21 / 10.3.31 / 10.2.40.

Description

The Information Schema `SQL_FUNCTIONS` table contains the list of MariaDB functions.

It contains a single column:

Column	Description
FUNCTION	Function name

The table is not a standard Information Schema table, and is a MariaDB extension.

Example

```
SELECT * FROM INFORMATION_SCHEMA.SQL_FUNCTIONS;
+---------------------------+
| FUNCTION                  |
+---------------------------+
| ADDDATE                   |
| ADD_MONTHS                |
| BIT_AND                   |
| BIT_OR                    |
| BIT_XOR                   |
| CAST                      |
| COUNT                     |
| CUME_DIST                 |
| CURDATE                   |
| CURTIME                   |
| DATE_ADD                  |
| DATE_SUB                  |
| DATE_FORMAT               |
| DECODE                    |
| DENSE_RANK                |
| EXTRACT                   |
| FIRST_VALUE               |
| GROUP_CONCAT              |
| JSON_ARRAYAGG             |
| JSON_OBJECTAGG            |
| LAG                       |
| LEAD                      |

Information Schema STATISTICS Table

The Information Schema `STATISTICS` table provides information about table indexes.

It contains the following columns:

Column	Description
TABLE_CATALOG	Always def.
TABLE_SCHEMA	Database name.
TABLE_NAME	Table name.
NON_UNIQUE	1 if the index can have duplicates, 0 if not.
INDEX_SCHEMA	Database name.
INDEX_NAME	Index name. The primary key is always named PRIMARY.

Column	Description
SEQ_IN_INDEX	The column sequence number, starting at 1.
COLUMN_NAME	Column name.
COLLATION	A for sorted in ascending order, or NULL for unsorted.
CARDINALITY	Estimate of the number of unique values stored in the index based on statistics stored as integers. Higher cardinalities usually mean a greater chance of the index being used in a join. Updated by the ANALYZE TABLE statement or myisamchk -a.
SUB_PART	NULL if the whole column is indexed, or the number of indexed characters if partly indexed.
PACKED	NULL if not packed, otherwise how the index is packed.
NULLABLE	YES if the column may contain NULLs, empty string if not.
INDEX_TYPE	Index type, one of BTREE, RTREE, HASH or FULLTEXT. See Storage Engine Index Types.
COMMENT	Index comments from the CREATE INDEX statement.
IGNORED	Whether or not an index will be ignored by the optimizer. See Ignored Indexes. From MariaDB 10.6.0.
CREATE_OPTIONS	Extra CREATE TABLE options.This column is available from MariaDB 13.0.

The SHOW INDEX statement produces similar output.

Example

```
SELECT * FROM INFORMATION_SCHEMA.STATISTICS\G
...
*************************** 85. row ***************************
TABLE_CATALOG: def
 TABLE_SCHEMA: test
   TABLE_NAME: table1
   NON_UNIQUE: 1
 INDEX_SCHEMA: test
   INDEX_NAME: col2
 SEQ_IN_INDEX: 1
  COLUMN_NAME: col2
    COLLATION: A
  CARDINALITY: 6
     SUB_PART: NULL
       PACKED: NULL
     NULLABLE:
   INDEX_TYPE: BTREE
      COMMENT:
INDEX_COMMENT:
...
```

Information Schema SYSTEM_VARIABLES Table

The Information Schema `SYSTEM_VARIABLES` table shows current values and various metadata of all system variables.

It contains the following columns:

Column	Description
VARIABLE_NAME	System variable name.
SESSION_VALUE	Session value of the variable or `NULL` if the variable only has a global scope.
GLOBAL_VALUE	Global value of the variable or `NULL` if the variable only has a session scope.
GLOBAL_VALUE_ORIGIN	How the global value is set — a compile-time default, auto-configured by the server, configuration file (or on a command line), with the SQL statement.
DEFAULT_VALUE	Compile-time default value of the variable.
VARIABLE_SCOPE	Global, session, or session-only.
VARIABLE_TYPE	Data type of the variable value.
VARIABLE_COMMENT	Help text, usually shown in `mariadbd --help --verbose`.
NUMERIC_MIN_VALUE	For numeric variables — minimal allowed value.
NUMERIC_MAX_VALUE	For numeric variables — maximal allowed value.
NUMERIC_BLOCK_SIZE	For numeric variables — a valid value must be a multiple of the “block size”.
ENUM_VALUE_LIST	For `ENUM`, `SET`, and `FLAGSET` variables — the list of recognized values.
READ_ONLY	Whether a variable can be set with the SQL statement. Note that many “read only” variables can still be set on the command line.
COMMAND_LINE_ARGUMENT	Whether an argument is required when setting the variable on the command line. `NULL` when a variable can not be set on the command line.
GLOBAL_VALUE_PATH	Which config file the variable got its value from. `NULL` if not set in any config file.
IS_DEPRECATED	Used to identify deprecated variables in the server configuration (in an option file or on the command line). Available from MariaDB 13.0.
DEPRECATED_REPLACEMENT	The replacement of a deprecated variable. If `NULL`, there is no replacement. Available from MariaDB 13.0.

Examples

Show Values of a Specific Variable

```
SELECT * FROM information_schema.SYSTEM_VARIABLES
  WHERE VARIABLE_NAME='JOIN_BUFFER_SIZE'\G
*************************** 1. row ***************************
        VARIABLE_NAME: JOIN_BUFFER_SIZE
        SESSION_VALUE: 131072
         GLOBAL_VALUE: 131072
  GLOBAL_VALUE_ORIGIN: COMPILE-TIME
       DEFAULT_VALUE: 131072
      VARIABLE_SCOPE: SESSION
       VARIABLE_TYPE: BIGINT UNSIGNED
    VARIABLE_COMMENT: The size of the buffer that is used for joins
    NUMERIC_MIN_VALUE: 128
    NUMERIC_MAX_VALUE: 18446744073709551615
   NUMERIC_BLOCK_SIZE: 128
      ENUM_VALUE_LIST: NULL
            READ_ONLY: NO
COMMAND_LINE_ARGUMENT: REQUIRED
        IS_DEPRECATED: NO
```

Show Deprecated Variables That are set in the Configuration File

This query shows variables used in your server deployment that are deprecated:

```
SELECT VARIABLE_NAME, GLOBAL_VALUE, DEFAULT_VALUE
 FROM INFORMATION_SCHEMA.SYSTEM_VARIABLES
 WHERE GLOBAL_VALUE_ORIGIN='CONFIG' AND IS_DEPRECATED = 'YES';
 -- Possible output
+----------------------+-------------+---------------+
| VARIABLE_NAME         | GLOBAL_VALUE | DEFAULT_VALUE |
+----------------------+-------------+---------------+
| INNODB_LRU_FLUSH_SIZE | 0            | 32            |
+----------------------+-------------+---------------+
```

Information Schema TABLE_CONSTRAINTS Table

The Information Schema `TABLE_CONSTRAINTS` table contains information about tables that have constraints.

It has the following columns:

Column	Description
CONSTRAINT_CATALOG	Always def.
CONSTRAINT_SCHEMA	Database name containing the constraint.
CONSTRAINT_NAME	Constraint name.
TABLE_SCHEMA	Database name.
TABLE_NAME	Table name.
CONSTRAINT_TYPE	Type of constraint; one of UNIQUE, PRIMARY KEY, FOREIGN KEY or CHECK.

The REFERENTIAL_CONSTRAINTS table has more information about foreign keys.

This page is licensed: CC BY-SA / Gnu FDL

Information Schema TABLE_PRIVILEGES Table

The Information Schema `TABLE_PRIVILEGES` table contains table privilege information derived from the mysql.tables_priv grant table.

It has the following columns:

Column	Description
GRANTEE	In the format user_name@host_name.
TABLE_CATALOG	Always def.
TABLE_SCHEMA	Database name.
TABLE_NAME	Table name.
PRIVILEGE_TYPE	One of SELECT, INSERT, UPDATE, REFERENCES, ALTER, INDEX, DROP or CREATE VIEW.
IS_GRANTABLE	Whether the user has the GRANT OPTION for this privilege.

Similar information can be accessed with the SHOW GRANTS statement. See the GRANT article for more about privileges.

The table only shows privileges granted on the table level. This differs from the Sys Schema privileges_by_table_by_level view, which shows all privileges, broken down by table.

For a description of the privileges that are shown in this table, see table privileges.

Information Schema TABLE_STATISTICS Table

The Information Schema `TABLE_STATISTICS` table shows statistics on table usage.

This is part of the User Statistics feature, which is not enabled by default.

It contains the following columns:

Field	Type	Notes
TABLE_SCHEMA	varchar(192)	The schema (database) name.
TABLE_NAME	varchar(192)	The table name.
ROWS_READ	bigint(21)	The number of rows read from the table.
ROWS_CHANGED	bigint(21)	The number of rows changed in the table.
ROWS_CHANGED_X_INDEXES	bigint(21)	The number of rows changed in the table, multiplied by the number of indexes changed.
ROWS_INSERTED	bigint(21)	From MariaDB 11.5
ROWS_UPDATED	bigint(21)	From MariaDB 11.5
ROWS_DELETED	bigint(21)	From MariaDB 11.5
KEY_READ_HITS	bigint(21)	From MariaDB 11.5
KEY_READ_MISSES	bigint(21)	From MariaDB 11.5

Example

```
SELECT * FROM INFORMATION_SCHEMA.TABLE_STATISTICS WHERE TABLE_NAME='user';
+--------------+------------+-----------+--------------+-----------------------+
| TABLE_SCHEMA | TABLE_NAME | ROWS_READ | ROWS_CHANGED | ROWS_CHANGED_X_INDEXES |
+--------------+------------+-----------+--------------+-----------------------+
| mysql        | user       |         5 |            2 |                     2 |
+--------------+------------+-----------+--------------+-----------------------+
```

Information Schema TABLES Table

CURRENT

The Information Schema table shows information about the various tables and views on the server.

< 11.2.0

The Information Schema table shows information about the various tables, excluding `TEMPORARY` tables, except for tables from the `Information Schema` database and views on the server.

It contains the following columns:

Column	Description
TABLE_CATALOG	Always `def`.
TABLE_SCHEMA	Database name.
TABLE_NAME	Table name.

Column	Description
TABLE_TYPE	One of `BASE TABLE` for a regular table, VIEW for a view, `SYSTEM VIEW` for Information Schema tables, `SYSTEM VERSIONED` for system-versioned tables, `SEQUENCE` for sequences or `TEMPORARY` for local temporary tables.
ENGINE	Storage Engine.
VERSION	Version number from the table's `.frm` file.
ROW_FORMAT	Row format (see InnoDB, Aria and MyISAM row formats).
TABLE_ROWS	Number of rows in the table. Some engines, such as XtraDB and InnoDB may store an estimate.
AVG_ROW_LENGTH	Average row length in the table.
DATA_LENGTH	For InnoDB/XtraDB, the index size, in pages, multiplied by the page size. For Aria and MyISAM, length of the data file, in bytes. For MEMORY, the approximate allocated memory.
MAX_DATA_LENGTH	Maximum length of the data file, ie the total number of bytes that could be stored in the table. Not used in XtraDB and InnoDB.
INDEX_LENGTH	Length of the index file.
DATA_FREE	Bytes allocated but unused. For InnoDB tables in a shared tablespace, the free space of the shared tablespace with small safety margin. An estimate in the case of partitioned tables - see the PARTITIONS table.
AUTO_INCREMENT	Next AUTO_INCREMENT value.
CREATE_TIME	Time the table was created. Some engines just return the ctime information from the file system layer here, in that case the value is not necessarily the table creation time but rather the time the file system metadata for it had last changed.
UPDATE_TIME	Time the table was last updated. On Windows, the timestamp is not updated on update, so MyISAM values will be inaccurate. In InnoDB, if shared tablespaces are used, will be NULL, while buffering can also delay the update, so the value will differ from the actual time of the last `UPDATE`, `INSERT` or `DELETE`.
CHECK_TIME	Time the table was last checked. Not kept by all storage engines, in which case will be `NULL`.
TABLE_COLLATION	Character set and collation.
CHECKSUM	Live checksum value, if any.
CREATE_OPTIONS	Extra CREATE TABLE options.
TABLE_COMMENT	Table comment provided when MariaDB created the table.
MAX_INDEX_LENGTH	Maximum index length (supported by MyISAM and Aria tables).
TEMPORARY	Set to `'Y'` for local temporary tables.

Although the table is standard in the Information Schema, all but `TABLE_CATALOG`, `TABLE_SCHEMA`, `TABLE_NAME`, `TABLE_TYPE`, `ENGINE` and `VERSION` are MySQL and MariaDB extensions.

SHOW TABLES lists all tables in a database.

Examples

```
SELECT * FROM information_schema.tables WHERE table_schema='test'\G
*************************** 1. row ***************************
   TABLE_CATALOG: def
    TABLE_SCHEMA: test
      TABLE_NAME: xx5
      TABLE_TYPE: BASE TABLE
          ENGINE: InnoDB
         VERSION: 10
      ROW_FORMAT: Dynamic
      TABLE_ROWS: 0
  AVG_ROW_LENGTH: 0
     DATA_LENGTH: 16384
 MAX_DATA_LENGTH: 0
    INDEX_LENGTH: 0
       DATA_FREE: 0
  AUTO_INCREMENT: NULL
     CREATE_TIME: 2020-11-18 15:57:10
     UPDATE_TIME: NULL
      CHECK_TIME: NULL
 TABLE_COLLATION: latin1_swedish_ci
        CHECKSUM: NULL
  CREATE_OPTIONS:
   TABLE_COMMENT:
MAX_INDEX_LENGTH: 0
       TEMPORARY: N
*************************** 2. row ***************************
   TABLE_CATALOG: def
    TABLE_SCHEMA: test
      TABLE_NAME: xx4
      TABLE_TYPE: BASE TABLE
          ENGINE: MyISAM
         VERSION: 10
      ROW_FORMAT: Fixed
      TABLE_ROWS: 0
  AVG_ROW_LENGTH: 0
     DATA_LENGTH: 0
 MAX_DATA_LENGTH: 1970324836974591
    INDEX_LENGTH: 1024
       DATA_FREE: 0
  AUTO_INCREMENT: NULL
     CREATE_TIME: 2020-11-18 15:56:57
     UPDATE_TIME: 2020-11-18 15:56:57
      CHECK_TIME: NULL
 TABLE_COLLATION: latin1_swedish_ci
        CHECKSUM: NULL
  CREATE_OPTIONS:
   TABLE_COMMENT:
MAX_INDEX_LENGTH: 17179868160
       TEMPORARY: N
...
```

Example with `temporary = 'y'`:

```
SELECT * FROM information_schema.tables WHERE temporary='y'\G
 *************************** 1. row ***************************
   TABLE_CATALOG: def
    TABLE_SCHEMA: information_schema
      TABLE_NAME: INNODB_FT_DELETED
      TABLE_TYPE: SYSTEM VIEW
          ENGINE: MEMORY
         VERSION: 11
      ROW_FORMAT: Fixed
      TABLE_ROWS: NULL
  AVG_ROW_LENGTH: 9
     DATA_LENGTH: 0
 MAX_DATA_LENGTH: 9437184
    INDEX_LENGTH: 0
       DATA_FREE: 0
  AUTO_INCREMENT: NULL
     CREATE_TIME: 2020-11-17 21:54:02
     UPDATE_TIME: NULL
      CHECK_TIME: NULL
 TABLE_COLLATION: utf8_general_ci
        CHECKSUM: NULL
  CREATE_OPTIONS: max_rows=1864135
   TABLE_COMMENT:
MAX_INDEX_LENGTH: 0
       TEMPORARY: Y
...
```

View Tables in Order of Size

Return a list of all tables in the database, ordered by size:

```
SELECT table_schema AS `DB`, table_name AS `TABLE`,
  ROUND(((data_length + index_length) / 1024 / 1024), 2) `Size (MB)`
  FROM information_schema.TABLES
  ORDER BY (data_length + index_length) DESC;

+--------------------+--------------------------------------+-----------+
| DB                 | Table                                | Size (MB) |
+--------------------+--------------------------------------+-----------+
| wordpress          | wp_simple_history_contexts           |      7.05 |
| wordpress          | wp_posts                             |      6.59 |
| wordpress          | wp_simple_history                    |      3.05 |
| wordpress          | wp_comments                          |      2.73 |
| wordpress          | wp_commentmeta                       |      2.47 |
| wordpress          | wp_simple_login_log                  |      2.03 |
...
```

Narrow down that information for a specific database:

```
SELECT table_schema AS `DB`, table_name AS `TABLE`,
  ROUND(((data_length + index_length) / 1024 / 1024), 2) `Size (MB)`
  FROM information_schema.TABLES
  WHERE table_schema='nation'
  ORDER BY (data_length + index_length) DESC;
+--------+------------------+-----------+
| DB     | TABLE            | Size (MB) |
+--------+------------------+-----------+
| nation | country_stats    |      0.41 |
| nation | countries        |      0.06 |
| nation | country_languages |      0.06 |
| nation | regions          |      0.03 |
| nation | guests           |      0.02 |
| nation | vips             |      0.02 |
| nation | region_areas     |      0.02 |
| nation | languages        |      0.02 |
| nation | continents       |      0.02 |
+--------+------------------+-----------+
```

Return information about a temporary table:

```
CREATE TEMPORARY TABLE foo.t1 (a INT);

SELECT * FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_SCHEMA='foo' AND TEMPORARY='y'\G
*************************** 1. row ***************************
   TABLE_CATALOG: def
    TABLE_SCHEMA: foo
      TABLE_NAME: t1
      TABLE_TYPE: TEMPORARY
...
       TEMPORARY: Y
```

Information Schema TABLESPACES Table

The Information Schema `TABLESPACES` table contains information about active tablespaces..

The table is a MariaDB and MySQL extension, and does not include information about InnoDB tablespaces.

Column	Description
TABLESPACE_NAME	
ENGINE	
TABLESPACE_TYPE	
LOGFILE_GROUP_NAME	
EXTENT_SIZE	
AUTOEXTEND_SIZE	
MAXIMUM_SIZE	
NODEGROUP_ID	
TABLESPACE_COMMENT	

This page is licensed: CC BY-SA / Gnu FDL

Information Schema THREAD_POOL_GROUPS Table

> **Note:**
>
> This table is available as of MariaDB 10.5.

The table provides information about thread pool groups, and contains the following columns:

Column	Description
GROUP_ID	the thread group this row is showing data for
CONNECTIONS	the number of clients currently connected to this thread group
THREADS	total number of threads in this group (ACTIVE+STANDBY+LISTENER)
ACTIVE_THREADS	number of threads currently executing a query
STANDBY_THREADS	number of threads in reserve that do not currently execute anything
QUEUE_LENGTH	number of client requests waiting for execution
HAS_LISTENER	whether there is an active listener thread right now, always 1 if thread_pool_dedicated_listener is ON
IS_STALLED	whether there's currently an active worker thread in this group that has exceeded thread_pool_stall_limit time

Setting thread_pool_dedicated_listener will give each group its own dedicated listener, and the listener thread will not pick up work items. As a result, the actual queue size in the table will be more exact, since IO requests are immediately dequeued from poll, without delay.

This page is licensed: CC BY-SA / Gnu FDL

Information Schema THREAD_POOL_QUEUES Table

> **Note:**
>
> This table is available from MariaDB 10.5.

The table provides information about thread pool queues, and contains the following columns:

Column	Description
GROUP_ID	the thread group this row is showing data for
POSITION	position in the groups queue
PRIORITY	request priority, see priority scheduling
CONNECTION_ID	ID of the client connection that submitted the queued request
QUEUEING_TIME_MICROSECONDS	how long the request has already been waiting in the queue in microseconds

Setting thread_poll_exact_stats will provides better queueing time statistics by using a high precision timestamp, at a small performance cost, for the time when the connection was added to the queue. This timestamp helps calculate the queuing time shown in the table.

Setting thread_pool_dedicated_listener will give each group its own dedicated listener, and the listener thread will not pick up work items. As a result, the queueing time in the table will be more exact, since IO requests are immediately dequeued from poll, without delay.

Information Schema THREAD_POOL_STATS Table

> **Note:**
>
> This table is available from MariaDB 10.5.

The table provides performance counter information for the thread pool, and contains the following columns:

Column	Description
GROUP_ID	the thread group this row is showing data for
THREAD_CREATIONS	number of threads created for this group so far
THREAD_CREATIONS_DUE_TO_STALL	number of threads created due to detected stalls
WAKES	standby thread wakeups
WAKES_DUE_TO_STALL	wakeups due to stalls
THROTTLES	how often thread creation was throttled, see also: thread-creation-throttling
STALLS	number of detected stalls
POLLS_BY_LISTENER	
POLLS_BY_WORKER	
DEQUEUES_BY_LISTENER	
DEQUEUES_BY_WORKER	

This page is licensed: CC BY-SA / Gnu FDL

Information Schema THREAD_POOL_WAITS Table

> **Note:**
>
> This table is available from MariaDB 10.5.

The table provides wait counters for the thread pool, and contains the following columns:

Column	Description
REASON	name of the reason for waiting, e.g. ROW_LOCK, DISKIO, NET …
COUNT	how often a wait for this specific reason has happened so far

This page is licensed: CC BY-SA / Gnu FDL

Information Schema TRIGGERED_UPDATE_COLUMNS

> **Note:**
>
> This table is available from MariaDB 12.2.

The Information Schema `TRIGGERED_UPDATE_COLUMNS` table shows columns specified in triggers for update operations.

Columns are displayed only if the user has non-SELECT privileges on the columns.

It contains the following columns:

Column	Description
TRIGGER_CATALOG	Always `def` in MariaDB.
TRIGGER_SCHEMA	Name of the database containing the trigger.

Column	Description
TRIGGER_NAME	Name of the trigger.
EVENT_OBJECT_CATALOG	Always `def` in MariaDB
EVENT_OBJECT_SCHEMA	Name of the database containing the table that the trigger is defined on.
EVENT_OBJECT_TABLE	Name of the table that the trigger is defined on.
EVENT_OBJECT_COLUMN	Name of the column that the trigger is defined on.

Examples

```
CREATE TABLE t (a INT, b INT, c INT);
INSERT INTO t VALUES (1, 2, 3);
CREATE TABLE t1 (a_old INT, b_old INT, a_new INT, b_new INT);
CREATE TABLE t2 (a_old INT, b_old INT, a_new INT, b_new INT);
CREATE TRIGGER trigger_before_update BEFORE UPDATE OF a, b ON t
  FOR EACH ROW INSERT INTO t1 VALUES (OLD.a, OLD.b, NEW.a, NEW.b);

SELECT * FROM INFORMATION_SCHEMA.TRIGGERED_UPDATE_COLUMNS\G
*************************** 1. row ***************************
 TRIGGER_CATALOG: def
TRIGGER_SCHEMA: test
TRIGGER_NAME: trigger_before_update
EVENT_OBJECT_CATALOG: def
EVENT_OBJECT_SCHEMA: test
EVENT_OBJECT_TABLE: t
EVENT_OBJECT_COLUMN: a
*************************** 2. row ***************************
TRIGGER_CATALOG: def
TRIGGER_SCHEMA: test
TRIGGER_NAME: trigger_before_update
EVENT_OBJECT_CATALOG: def
EVENT_OBJECT_SCHEMA: test
EVENT_OBJECT_TABLE: t
EVENT_OBJECT_COLUMN: b
```

This page is licensed: CC BY-SA / Gnu FDL

Information Schema TRIGGERS Table

The Information Schema `TRIGGERS` table contains information about triggers.

It has the following columns:

Column	Description
TRIGGER_CATALOG	Always def.
TRIGGER_SCHEMA	Database name in which the trigger occurs.
TRIGGER_NAME	Name of the trigger.
EVENT_MANIPULATION	The event that activates the trigger. Prior to MariaDB 12.0, one of `INSERT`, `UPDATE` or `DELETE`. From MariaDB 12.0, can contain multiple values, comma-separated.
EVENT_OBJECT_CATALOG	Always def.
EVENT_OBJECT_SCHEMA	Database name on which the trigger acts.
EVENT_OBJECT_TABLE	Table name on which the trigger acts.
ACTION_ORDER	Indicates the order that the action will be performed in (of the list of a table's triggers with identical `EVENT_MANIPULATION` and `ACTION_TIMING` values). See the FOLLOWS/PRECEDES clauses.

Column	Description
ACTION_CONDITION	`NULL`
ACTION_STATEMENT	Trigger body, UTF-8 encoded.
ACTION_ORIENTATION	Always ROW.
ACTION_TIMING	Whether the trigger acts `BEFORE` or `AFTER` the event that triggers it.
ACTION_REFERENCE_OLD_TABLE	Always `NULL`.
ACTION_REFERENCE_NEW_TABLE	Always `NULL`.
ACTION_REFERENCE_OLD_ROW	Always `OLD`.
ACTION_REFERENCE_NEW_ROW	Always `NEW`.
CREATED	Always `NULL`.
SQL_MODE	The SQL_MODE when the trigger was created, and which it uses for execution.
DEFINER	The account that created the trigger, in the form user_name@host_name
CHARACTER_SET_CLIENT	The client character set when the trigger was created, from the session value of the character_set_client system variable.
COLLATION_CONNECTION	The client collation when the trigger was created, from the session value of the collation_connection system variable.
DATABASE_COLLATION	Collation of the associated database.

Queries to the `TRIGGERS` table return information even if the user doesn't have `SELECT` privileges on the columns. The columns `ACTION_CONDITION`, `ACTION_STATEMENT` and `DEFINER` are `NULL` unless the user has the `TRIGGER` privilege. Similar information is returned by the SHOW TRIGGERS statement.

Information Schema USER_PRIVILEGES Table

The Information Schema `USER_PRIVILEGES` table contains global user privilege information derived from the mysql.global_priv grant table.

It contains the following columns:

Column	Description
GRANTEE	In the format user_name@host_name.
TABLE_CATALOG	Always def.

Column	Description
PRIVILEGE_TYPE	The specific privilege, for example CREATE USER, RELOAD, SHUTDOWN, SELECT, INSERT, UPDATE or REFERENCES.
IS_GRANTABLE	Whether the user has the GRANT OPTION for this privilege.

The database, table and column privileges returned here are the ones granted on all databases and tables, and by implication all columns.

Similar information can be accessed with the SHOW GRANTS statement. See the GRANT article for more about privileges.

This information is also stored in the mysql.global_priv table, in the `mysql` system database.

This page is licensed: CC BY-SA / Gnu FDL

Information Schema USER_STATISTICS Table

The Information Schema `USER_STATISTICS` table holds statistics about user activity. This is part of the User Statistics feature, which is not enabled by default.

You can use this table to find out such things as which user is causing the most load and which users are being abusive. You can also use this table to measure how close to capacity the server may be.

It contains the following columns:

Field	Type	Notes
USER	varchar(48)	The username. The value '#mysql_system_user#' appears when there is no username (such as for the slave SQL thread).
TOTAL_CONNECTIONS	int(11)	The number of connections created for this user.
CONCURRENT_CONNECTIONS	int(11)	The number of concurrent connections for this user.
CONNECTED_TIME	int(11)	The cumulative number of seconds elapsed while there were connections from this user.
BUSY_TIME	double	The cumulative number of seconds there was activity on connections from this user.
CPU_TIME	double	The cumulative CPU time elapsed while servicing this user's connections.
BYTES_RECEIVED	bigint(21)	The number of bytes received from this user's connections.
BYTES_SENT	bigint(21)	The number of bytes sent to this user's connections.
BINLOG_BYTES_WRITTEN	bigint(21)	The number of bytes written to the binary log from this user's connections.
ROWS_READ	bigint(21)	The number of rows read by this user's connections.
ROWS_SENT	bigint(21)	The number of rows sent by this user's connections.
ROWS_DELETED	int(21)	The number of rows deleted by this user's connections.
ROWS_INSERTED	bigint(21)	The number of rows inserted by this user's connections.
ROWS_UPDATED	bigint(21)	The number of rows updated by this user's connections.
KEY_READ_HITS	bigint(21)	From MariaDB 11.5

Field	Type	Notes
KEY_READ_MISSES	bigint(21)	From MariaDB 11.5
SELECT_COMMANDS	bigint(21)	The number of SELECT commands executed from this user's connections.
UPDATE_COMMANDS	bigint(21)	The number of UPDATE commands executed from this user's connections.
OTHER_COMMANDS	bigint(21)	The number of other commands executed from this user's connections.
COMMIT_TRANSACTIONS	bigint(21)	The number committed transactions. Note that in autocommit mode every statement is a separate transaction.
ROLLBACK_TRANSACTIONS	bigint(21)	The number of transactions that were rolled back.
DENIED_CONNECTIONS	bigint(21)	The number of connections denied to this user.
LOST_CONNECTIONS	bigint(21)	The number of this user's connections that were terminated uncleanly.
ACCESS_DENIED	bigint(21)	The number of times this user's connections issued commands that were denied.
EMPTY_QUERIES	bigint(21)	The number of times this user's connections sent queries to the server that did not return data to the client (a per-user aggregate of the empty_queries status variable).
TOTAL_SSL_CONNECTIONS	bigint(21)	The number of TLS connections created for this user.
MAX_STATEMENT_TIME_EXCEEDED	bigint(21)	The number of times a statement was aborted, because it was executed longer than its MAX_STATEMENT_TIME threshold.

Example

```
SELECT * FROM information_schema.USER_STATISTICS\G
*************************** 1. row ***************************
                 USER: root
     TOTAL_CONNECTIONS: 1
CONCURRENT_CONNECTIONS: 0
        CONNECTED_TIME: 297
             BUSY_TIME: 0.001725
              CPU_TIME: 0.001982
        BYTES_RECEIVED: 388
            BYTES_SENT: 2327
  BINLOG_BYTES_WRITTEN: 0
            ROWS_READ: 0
            ROWS_SENT: 12
         ROWS_DELETED: 0
        ROWS_INSERTED: 13
         ROWS_UPDATED: 0
       SELECT_COMMANDS: 4
       UPDATE_COMMANDS: 0
        OTHER_COMMANDS: 3
   COMMIT_TRANSACTIONS: 0
 ROLLBACK_TRANSACTIONS: 0
    DENIED_CONNECTIONS: 0
      LOST_CONNECTIONS: 0
         ACCESS_DENIED: 0
         EMPTY_QUERIES: 1
```

Information Schema USER_VARIABLES Table

Description

The `USER_VARIABLES` table is created when the user_variables plugin is enabled, and contains information about user-defined variables.

The table contains the following columns:

Column	Description
VARIABLE_NAME	Variable name.
VARIABLE_VALUE	Variable value.
VARIABLE_TYPE	Variable type.
CHARACTER_SET_NAME	Character set.

User variables are reset and the table emptied with the FLUSH USER_VARIABLES statement. `SHOW USER_VARIABLES` displays a subset of the data.

Example

```
SET @v1 = 0;
SET @v2 = 'abc';
SET @v3 = CAST(123 AS CHAR(5));

SELECT * FROM information_schema.USER_VARIABLES ORDER BY VARIABLE_NAME;
+---------------+----------------+---------------+--------------------+
| VARIABLE_NAME | VARIABLE_VALUE | VARIABLE_TYPE | CHARACTER_SET_NAME |
+---------------+----------------+---------------+--------------------+
| v1            | 0              | INT           | latin1             |
| v2            | abc            | VARCHAR       | utf8               |
| v3            | 123            | VARCHAR       | utf8               |
+---------------+----------------+---------------+--------------------+

SHOW USER_VARIABLES;
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| v3            | 123   |
| v2            | abc   |
| v1            | 0     |
+---------------+-------+
```

Information Schema USERS Table

> **Note:**
>
> This table is available from MariaDB 11.5.

The Information Schema `USERS` table contains information about users, password expiry, and the limits set by max_password_errors. Unprivileged users can access their own data, which is different to what mysql.global_priv provides.

It contains the following columns:

Column	Description
USER	In the format user_name@host_name.
PASSWORD_ERRORS	A current accumulated value of consecutive password login failures. If password_errors is not applicable for the user (see max_password_errors), PASSWORD_ERRORS will be NULL. Only password login attempts with nonempty password are taken into account.
PASSWORD_EXPIRATION_TIME	A timestamp with the exact point in time calculated from password_last_changed and password_lifetime (i.e. days) stored for the user.

Information Schema WSREP_BF_ABORTS

> **Note:**
>
> This plugin is used in MariaDB Galera Cluster.

> **Note:**
>
> This plugin is available as of MariaDB Enterprise Server 11.8.

This table contains execution state information for Galera threads. The respective plugin is not installed by default — you have to install it.

The table displays the history of BF[44] aborts. It has these columns:

- TIME - Datetime when bf abort happened
- VICTIM_TRX_ID - Victim trx ID or NULL
- VICTIM_THREAD_ID - Victim thread
- THD ID VICTIM_QUERY_ID - Victim query id
- VICTIM_SEQNO - Victim TO seqno associated with victim transaction
- VICTIM_CLIENT_STATE - Victim thread wsrep client state at the moment when BF abort attempt happened
- VICTIM_CLIENT_MODE - Victim thread wsrep client mode
- VICTIM_TRX_STATE - Victim thread wsrep transaction state at the moment when BF abort attempt happened
- VICTIM_LOCK - Victim lock information
- BF_TRX_ID - BF thread transaction ID
- BF_THREAD_ID - BF thread THD ID
- BF_QUERY_ID - BF query id
- BF_SEQNO - TO sequence number associated with BF transaction
- BF_CLIENT_STATE - BF thread wsrep client state
- BF_CLIENT_MODE - BF thread wsrep client mode
- BF_TRX_STATE - BF thread wsrep transaction state
- BF_LOCK - Information about the lock which BF thread tried to acquire
- SPACE_ID - Lock space_id in case of record or table lock
- PAGE_NO - Lock page_no in case of record lock
- INDEX_NAME - Record lock index name
- TABLE_NAME - Lock table name

Example output:

```
SELECT * FROM INFORMATION_SCHEMA.WSREP_BF_ABORT_HISTORY LIMIT 100;
+----------------------------+---------------+------------------+-----------------+--------------+-------
--------------+--------------------+------------------+-----------------------------+-----------+---------
-----+-------------+----------+-----------------+----------------+--------------+-----------------------
----+----------+---------+------------+------------------+
| TIME                       | VICTIM_TRX_ID | VICTIM_THREAD_ID | VICTIM_QUERY_ID | VICTIM_SEQNO |
VICTIM_CLIENT_STATE | VICTIM_CLIENT_MODE | VICTIM_TRX_STATE | VICTIM_LOCK                | BF_TRX_ID |
BF_THREAD_ID | BF_QUERY_ID | BF_SEQNO | BF_CLIENT_STATE | BF_CLIENT_MODE | BF_TRX_STATE | BF_LOCK

Information Schema WSREP_CERT_KEYS

> **Note:**
>
> This table is used in MariaDB Galera Cluster.

> **Note:**
>
> This table is available as of MariaDB Enterprise Server 11.8.

The Wsrep certification keys, the primary keys of changed rows, are collected into a write set for Galera Cluster's certification-based replication. The write set is used to ensure data consistency by detecting conflicting transactions before they commit. The `WSREP_CERT_INFO` plugin exposes wsrep certification keys in two information schema tables: `WSREP_CERT_KEYS` (this table), and `WSREP_CERT_KEYS_HISTORY`.

There are several key types.

Exclusive

The Exclusive key type is used when a transaction inserts, updates, or deletes a row. Example:

```
CREATE TABLE parent (f1 TINYINT PRIMARY KEY, f2 TINYINT)engine=innodb;
START TRANSACTION;
INSERT INTO parent VALUES (1, 3);
SELECT * FROM INFORMATION_SCHEMA.WSREP_CERT_KEYS;
COMMIT;
+--------+-----------------------------+-----------+
| THD_ID | KEY_STRING                  | KEY_TYPE  |
+--------+-----------------------------+-----------+
|      9 | 74657374 706172656E74 0001  | exclusive |
+--------+-----------------------------+-----------+
1 row in set (0.001 sec)
```

Reference

The Reference key type is used when a `FOREIGN KEY` constraint is defined with referenced table key tpe set as `REFERENCE`. In the example, `706172656E74` is a hexadecimal value for 'parent'. Example:

```
CREATE TABLE parent (f1 TINYINT PRIMARY KEY, f2 TINYINT) engine=innodb;
CREATE TABLE child (f1 TINYINT PRIMARY KEY, f2 TINYINT, FOREIGN KEY (f2) REFERENCES parent(f1))
engine=innodb;

START TRANSACTION;
INSERT INTO parent VALUES (1, 2);
SELECT KEY_STRING, KEY_TYPE FROM INFORMATION_SCHEMA.WSREP_CERT_KEYS;
+-----------------------------+-----------+
| KEY_STRING                  | KEY_TYPE  |
+-----------------------------+-----------+
| 74657374 706172656E74 0001  | exclusive |
+-----------------------------+-----------+
1 row in set (0.001 sec)
COMMIT;

START TRANSACTION;

Update

The Update key type is used when a transaction updates a row and `wsrep_protocol_version` is greater than 4. Otherwise, the Exclusive key type is used. Example:

```
CREATE TABLE parent (f1 TINYINT PRIMARY KEY, f2 TINYINT)engine=innodb;
update parent set f2=1;

SELECT KEY_STRING, KEY_TYPE FROM INFORMATION_SCHEMA.WSREP_CERT_KEYS;
+-----------------------------+----------+
| KEY_STRING                  | KEY_TYPE |
+-----------------------------+----------+
| 74657374 706172656E74 0001  | update   |
+-----------------------------+----------+
1 row in set (0.001 sec)
```

Shared

This key type is used when a referenced table update happens, and `wsrep_protocol_version` is smaller than 4.

Information Schema WSREP_MEMBERSHIP Table

The `WSREP_STATUS` table makes Galera node cluster membership information available through the Information Schema. The same information can be returned using the SHOW WSREP_MEMBERSHIP statement. Only users with the SUPER can access information from this table.

The `WSREP_MEMBERSHIP` table is part of the WSREP_INFO plugin.

Example

```
SELECT * FROM information_schema.WSREP_MEMBERSHIP;
+-------+--------------------------------------+-------+-----------------+
| INDEX | UUID                                 | NAME  | ADDRESS         |
+-------+--------------------------------------+-------+-----------------+
|     0 | 46da96e3-6e9e-11e4-95a2-f609aa5444b3 | node1 | 10.0.2.15:16000 |
|     1 | 5f6bc72a-6e9e-11e4-84ed-57ec6780a3d3 | node2 | 10.0.2.15:16001 |
|     2 | 7473fd75-6e9e-11e4-91de-0b541ad91bd0 | node3 | 10.0.2.15:16002 |
+-------+--------------------------------------+-------+-----------------+
```

Information Schema WSREP_STATUS Table

The `WSREP_STATUS` table makes Galera node cluster status information available through the Information Schema. The same information can be returned using the SHOW WSREP_STATUS statement. Only users with the SUPER

privilege can access information from this table.

The `WSREP_STATUS` table is part of the WSREP_INFO plugin.

Example

```
SELECT * FROM information_schema.WSREP_STATUS\G
*************************** 1. row ***************************
         NODE_INDEX: 0
        NODE_STATUS: Synced
     CLUSTER_STATUS: Primary
       CLUSTER_SIZE: 3
 CLUSTER_STATE_UUID: 00b0fbad-6e84-11e4-8a8b-376f19ce8ee7
CLUSTER_STATE_SEQNO: 2
    CLUSTER_CONF_ID: 3
                GAP: NO
   PROTOCOL_VERSION: 3
```

Information Schema WSREP_THD_STATE

> **Note:**
>
> This table is used in MariaDB Galera Cluster.

> **Note:**
>
> This table is available as of MariaDB Enterprise Server 11.8.

This table contains execution state information for Galera threads, and has these columns:

- ID - Thread ID
- OS_THREAD_ID - Os thread ID
- CLIENT_MODE - Client mode (local, high priority, toi…)
- CLIENT_STATE - Wsrep query state (idle, exec, result…)
- TRANSACTION_STATE - Wsrep transaction state or “none” if no active transaction
- SEQNO - Commit order seqno if assigned, otherwise -1
- DEPENDS_ON - Depends on seqno if assigned, otherwise -1
  The table must have low overhead (populated only when queried) and must be enabled at all times (not plugin or plugin must be loaded by default).
- GTID - transaction GTID assigned during commit phase

Example output:

```
SELECT * FROM information_schema.wsrep_thd_info;
ID  OS_THREAD_ID    MODE    STATE   TRANSACTION_ID  TRANSACTION_STATE   SEQNO   DEPENDS_ON  GTID
14  128875466565312 local   exec    64  executing   NULL    NULL    NULL
13  128875466872512 local   exec    61  committing  9   3   0-1-7
12  128875467179712 local   idle    NULL    aborted NULL    NULL    NULL
2   128875634570944 high priority   exec    NULL    executing   NULL    NULL    NULL
1   128875634878144 local   none    NULL    executing   NULL    NULL    NULL
```

There is also an `INFORMATION_SCHEMA.WSREP_THD_STATE_HISTORY` table that contains the history of execution state information for Galera threads.

Information Schema INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET Tables

The `INNODB_CMP_PER_INDEX` and `INNODB_CMP_PER_INDEX_RESET` tables contain status information on compression operations related to compressed XtraDB/InnoDB tables, grouped by individual indexes. These tables are only populated if the innodb_cmp_per_index_enabled system variable is set to `ON`.

The PROCESS privilege is required to query this table.

These tables contains the following columns:

Column Name	Description
DATABASE_NAME	Database containing the index.
TABLE_NAME	Table containing the index.
INDEX_NAME	Other values are totals which refer to this index's compression.
COMPRESS_OPS	How many times a page of INDEX_NAME has been compressed. This happens when a new page is created because the compression log runs out of space. This value includes both successful operations and compression failures.
COMPRESS_OPS_OK	How many times a page of INDEX_NAME has been successfully compressed. This value should be as close as possible to COMPRESS_OPS. If it is notably lower, either avoid compressing some tables, or increase the KEY_BLOCK_SIZE for some compressed tables.
COMPRESS_TIME	Time (in seconds) spent to compress pages of the size PAGE_SIZE. This value includes time spent in compression failures.
UNCOMPRESS_OPS	How many times a page of INDEX_NAME has been uncompressed. This happens when an uncompressed version of a page is created in the buffer pool, or when a compression failure occurs.
UNCOMPRESS_TIME	Time (in seconds) spent to uncompress pages of INDEX_NAME.

These tables can be used to measure the effectiveness of XtraDB/InnoDB compression, per table or per index. The values in these tables show which tables perform better with index compression, and which tables cause too many *compression failures* or perform too many compression/uncompression operations. When compression performs badly for a table, this might mean that you should change its `KEY_BLOCK_SIZE`, or that the table should not be compressed.

`INNODB_CMP_PER_INDEX` and `INNODB_CMP_PER_INDEX_RESET` have the same columns and always contain the same values, but when `INNODB_CMP_PER_INDEX_RESET` is queried, both the tables are cleared. `INNODB_CMP_PER_INDEX_RESET` can be used, for example, if a script periodically logs the performances of compression in the last period of time. `INNODB_CMP_PER_INDEX` can be used to see the cumulated statistics.

See Also

Other tables that can be used to monitor XtraDB/InnoDB compressed tables:

- INNODB_CMP and INNODB_CMP_RESET
- INNODB_CMPMEM and INNODB_CMPMEM_RESET

This page is licensed: CC BY-SA / Gnu FDL

Information Schema INNODB_BUFFER_PAGE Table

The Information Schema `INNODB_BUFFER_PAGE` table contains information about pages in the buffer pool.

Querying this table can have a noticeable performance impact on a production server.

The `PROCESS` privilege is required to view the table.

It has the following columns:

Column	Description
POOL_ID	Buffer Pool identifier. From MariaDB 10.5.1 returns a value of 0, since multiple InnoDB buffer pool instances has been removed.
BLOCK_ID	Buffer Pool Block identifier.
SPACE	Tablespace identifier. Matches the SPACE value in the INNODB_SYS_TABLES table.
PAGE_NUMBER	Buffer pool page number.
PAGE_TYPE	Page type; one of allocated (newly-allocated page), index (B-tree node), undo_log (undo log page), inode (index node), ibuf_free_list (insert buffer free list), ibuf_bitmap (insert buffer bitmap), system (system page), trx_system (transaction system data), file_space_header (file space header), extent_descriptor (extent descriptor page), blob (uncompressed blob page), compressed_blob (first compressed blob page), compressed_blob2 (subsequent compressed blob page) or unknown.
FLUSH_TYPE	Flush type.
FIX_COUNT	Count of the threads using this block in the buffer pool. When it is zero, the block can be evicted from the buffer pool.
IS_HASHED	Whether or not a hash index has been built on this page.
NEWEST_MODIFICATION	Most recent modification's Log Sequence Number.
OLDEST_MODIFICATION	Oldest modification's Log Sequence Number.
ACCESS_TIME	Abstract number representing the time the page was first accessed.
TABLE_NAME	Table that the page belongs to.
INDEX_NAME	Index that the page belongs to, either a clustered index or a secondary index.
NUMBER_RECORDS	Number of records the page contains.
DATA_SIZE	Size in bytes of all the records contained in the page.
COMPRESSED_SIZE	Compressed size in bytes of the page, or NULL for pages that aren't compressed.

Column	Description
PAGE_STATE	Page state; one of FILE_PAGE (page from a file) or MEMORY (page from an in-memory object) for valid data, or one of NULL, READY_FOR_USE, NOT_USED, REMOVE_HASH.
IO_FIX	Whether there is I/O pending for the page; one of IO_NONE (no pending I/O), IO_READ (read pending), IO_WRITE (write pending).
IS_OLD	Whether the page is old or not.
FREE_PAGE_CLOCK	Freed_page_clock counter, which tracks the number of blocks removed from the end of the least recently used (LRU) list, at the time the block was last placed at the head of the list.

The related INFORMATION_SCHEMA.INNODB_BUFFER_PAGE_LRU table contains the same information, but with an LRU (least recently used) position rather than block id.

Examples

```
DESC information_schema.innodb_buffer_page;
+---------------------+---------------------+------+-----+---------+-------+
| Field               | Type                | Null | Key | Default | Extra |
+---------------------+---------------------+------+-----+---------+-------+
| POOL_ID             | bigint(21) unsigned | NO   |     | 0       |       |
| BLOCK_ID            | bigint(21) unsigned | NO   |     | 0       |       |
| SPACE               | bigint(21) unsigned | NO   |     | 0       |       |

Information Schema INNODB_BUFFER_PAGE_LRU Table

The Information Schema `INNODB_BUFFER_PAGE_LRU` table contains information about pages in the buffer pool and how they are ordered for eviction purposes.

The `PROCESS` privilege is required to view the table.

It has the following columns:

Column	Description
POOL_ID	Buffer Pool identifier. From MariaDB 10.5.1 returns a value of 0, since multiple InnoDB buffer pool instances has been removed.
LRU_POSITION	LRU (Least recently-used), for determining eviction order from the buffer pool.
SPACE	Tablespace identifier. Matches the SPACE value on the INNODB_SYS_TABLES table.
PAGE_NUMBER	Buffer pool page number.
PAGE_TYPE	Page type; one of allocated (newly-allocated page), index (B-tree node), undo_log (undo log page), inode (index node), ibuf_free_list (insert buffer free list), ibuf_bitmap (insert buffer bitmap), system (system page), trx_system (transaction system data), file_space_header (file space header), extent_descriptor (extent descriptor page), blob (uncompressed blob page), compressed_blob (first compressed blob page), compressed_blob2 (subsequent compressed blob page) or unknown.
FLUSH_TYPE	Flush type. 0= FLUSH_KEEP, 1 =FLUSH_RELEASE, 2 = FLUSH_IGNORE_CHANGED, 3= FLUSH_FORCE_WRITE
FIX_COUNT	Count of the threads using this block in the buffer pool. When it is zero, the block can be evicted from the buffer pool.

Column	Description
IS_HASHED	Whether or not a hash index has been built on this page.
NEWEST_MODIFICATION	Most recent modification's Log Sequence Number.
OLDEST_MODIFICATION	Oldest modification's Log Sequence Number.
ACCESS_TIME	Abstract number representing the time the page was first accessed.
TABLE_NAME	Table that the page belongs to.
INDEX_NAME	Index that the page belongs to, either a clustered index or a secondary index.
NUMBER_RECORDS	Number of records the page contains.
DATA_SIZE	Size in bytes of all the records contained in the page.
COMPRESSED_SIZE	Compressed size in bytes of the page, or NULL for pages that aren't compressed.
PAGE_STATE	Page state; one of FILE_PAGE (page from a file) or MEMORY (page from an in-memory object) for valid data, or one of NULL, READY_FOR_USE, NOT_USED, REMOVE_HASH.
IO_FIX	Whether there is I/O pending for the page; one of IO_NONE (no pending I/O), IO_READ (read pending), IO_WRITE (write pending).
IS_OLD	Whether the page is old or not.
FREE_PAGE_CLOCK	Freed_page_clock counter, which tracks the number of blocks removed from the end of the LRU list, at the time the block was last placed at the head of the list.

The related INFORMATION_SCHEMA.INNODB_BUFFER_PAGE table contains the same information, but with a block id rather than LRU position.

Example

```
DESC information_schema.innodb_buffer_page_lru;
+---------------------+---------------------+------+-----+---------+-------+
| Field               | Type                | Null | Key | Default | Extra |
+---------------------+---------------------+------+-----+---------+-------+
| POOL_ID             | bigint(21) unsigned | NO   |     | 0       |       |
| LRU_POSITION        | bigint(21) unsigned | NO   |     | 0       |       |
| SPACE               | bigint(21) unsigned | NO   |     | 0       |       |
| PAGE_NUMBER         | bigint(21) unsigned | NO   |     | 0       |       |
| PAGE_TYPE           | varchar(64)         | YES  |     | NULL    |       |
| FLUSH_TYPE          | bigint(21) unsigned | NO   |     | 0       |       |
| FIX_COUNT           | bigint(21) unsigned | NO   |     | 0       |       |
| IS_HASHED           | varchar(3)          | YES  |     | NULL    |       |
| NEWEST_MODIFICATION | bigint(21) unsigned | NO   |     | 0       |       |
| OLDEST_MODIFICATION | bigint(21) unsigned | NO   |     | 0       |       |
| ACCESS_TIME         | bigint(21) unsigned | NO   |     | 0       |       |
| TABLE_NAME          | varchar(1024)       | YES  |     | NULL    |       |
| INDEX_NAME          | varchar(1024)       | YES  |     | NULL    |       |
| NUMBER_RECORDS      | bigint(21) unsigned | NO   |     | 0       |       |

Information Schema INNODB_BUFFER_POOL_PAGES Table

The Information Schema `INNODB_BUFFER_POOL_PAGES` table is a Percona enhancement, and is only available for XtraDB, not InnoDB (see XtraDB and InnoDB). It contains a record for each page in the buffer pool.

It has the following columns:

Column	Description
PAGE_TYPE	Type of page; one of index, undo_log, inode, ibuf_free_list, allocated, bitmap, sys, trx_sys, fsp_hdr, xdes, blob, zblob, zblob2 and unknown.

Column	Description
SPACE_ID	Tablespace ID.
PAGE_NO	Page offset within tablespace.
LRU_POSITION	Page position in the LRU (least-recently-used) list.
FIX_COUNT	Page reference count, incremented each time the page is accessed. 0 if the page is not currently being accessed.
FLUSH_TYPE	Flush type of the most recent flush.0 (LRU), 2 (flush_list)

This page is licensed: CC BY-SA / Gnu FDL

Information Schema INNODB_BUFFER_POOL_PAGES_BLOB Table

The Information Schema `INNODB_BUFFER_POOL_PAGES_BLOB` table is a Percona enhancement, and is only available for XtraDB, not InnoDB (see XtraDB and InnoDB). It contains information about buffer pool blob pages.

It has the following columns:

Column	Description
SPACE_ID	Tablespace ID.
PAGE_NO	Page offset within tablespace.
COMPRESSED	1 if the blob contains compressed data, 0 if not.
PART_LEN	Page data length.
NEXT_PAGE_NO	Next page number.
LRU_POSITION	Page position in the LRU (least-recently-used) list.
FIX_COUNT	Page reference count, incremented each time the page is accessed. 0 if the page is not currently being accessed.
FLUSH_TYPE	Flush type of the most recent flush.0 (LRU), 2 (flush_list)

This page is licensed: CC BY-SA / Gnu FDL

Information Schema INNODB_BUFFER_POOL_PAGES_INDEX Table

The Information Schema `INNODB_BUFFER_POOL_PAGES` table is a Percona enhancement, and is only available for XtraDB, not InnoDB (see XtraDB and InnoDB). It contains information about buffer pool index pages.

It has the following columns:

Column	Description
INDEX_ID	Index name
SPACE_ID	Tablespace ID
PAGE_NO	Page offset within tablespace.
N_RECS	Number of user records on the page.
DATA_SIZE	Total data size in bytes of records in the page.
HASHED	1 if the block is in the adaptive hash index, 0 if not.
ACCESS_TIME	Page's last access time.
MODIFIED	1 if the page has been modified since being loaded, 0 if not.
DIRTY	1 if the page has been modified since it was last flushed, 0 if not
OLD	1 if the page in the in the old blocks of the LRU (least-recently-used) list, 0 if not.
LRU_POSITION	Position in the LRU (least-recently-used) list.

Column	Description
FIX_COUNT	Page reference count, incremented each time the page is accessed. 0 if the page is not currently being accessed.
FLUSH_TYPE	Flush type of the most recent flush.0 (LRU), 2 (flush_list)

This page is licensed: CC BY-SA / Gnu FDL

Information Schema INNODB_BUFFER_POOL_STATS Table

The Information Schema `INNODB_BUFFER_POOL_STATS` table contains information about pages in the buffer pool, similar to what is returned with the SHOW ENGINE INNODB STATUS statement.

The `PROCESS` privilege is required to view the table.

It has the following columns:

Column	Description
POOL_ID	Buffer Pool identifier. From MariaDB 10.5.1 returns a value of 0, since multiple InnoDB buffer pool instances has been removed.
POOL_SIZE	Size in pages of the buffer pool.
FREE_BUFFERS	Number of free pages in the buffer pool.
DATABASE_PAGES	Total number of pages in the buffer pool.
OLD_DATABASE_PAGES	Number of pages in the old sublist.
MODIFIED_DATABASE_PAGES	Number of dirty pages.
PENDING_DECOMPRESS	Number of pages pending decompression.
PENDING_READS	Pending buffer pool level reads.
PENDING_FLUSH_LRU	Number of pages in the LRU pending flush.
PENDING_FLUSH_LIST	Number of pages in the flush list pending flush.
PAGES_MADE_YOUNG	Pages moved from the old sublist to the new sublist.
PAGES_NOT_MADE_YOUNG	Pages that have remained in the old sublist without moving to the new sublist.
PAGES_MADE_YOUNG_RATE	Hits that cause blocks to move to the top of the new sublist.
PAGES_MADE_NOT_YOUNG_RATE	Hits that do not cause blocks to move to the top of the new sublist due to the innodb_old_blocks delay not being met.
NUMBER_PAGES_READ	Number of pages read.
NUMBER_PAGES_CREATED	Number of pages created.
NUMBER_PAGES_WRITTEN	Number of pages written.
PAGES_READ_RATE	Number of pages read since the last printout divided by the time elapsed, giving pages read per second.
PAGES_CREATE_RATE	Number of pages created since the last printout divided by the time elapsed, giving pages created per second.
PAGES_WRITTEN_RATE	Number of pages written since the last printout divided by the time elapsed, giving pages written per second.
NUMBER_PAGES_GET	Number of logical read requests.
HIT_RATE	Buffer pool hit rate.
YOUNG_MAKE_PER_THOUSAND_GETS	For every 1000 gets, the number of pages made young.
NOT_YOUNG_MAKE_PER_THOUSAND_GETS	For every 1000 gets, the number of pages not made young.

Column	Description
NUMBER_PAGES_READ_AHEAD	Number of pages read ahead.
NUMBER_READ_AHEAD_EVICTED	Number of pages read ahead by the read-ahead thread that were later evicted without being accessed by any queries.
READ_AHEAD_RATE	Pages read ahead since the last printout divided by the time elapsed, giving read-ahead rate per second.
READ_AHEAD_EVICTED_RATE	Read-ahead pages not accessed since the last printout divided by time elapsed, giving the number of read-ahead pages evicted without access per second.
LRU_IO_TOTAL	Total least-recently used I/O.
LRU_IO_CURRENT	Least-recently used I/O for the current interval.
UNCOMPRESS_TOTAL	Total number of pages decompressed.
UNCOMPRESS_CURRENT	Number of pages decompressed in the current interval

Information Schema INNODB_CHANGED_PAGES Table

The Information Schema `INNODB_CHANGED_PAGES` Table contains data about modified pages from the bitmap file. It is updated at checkpoints by the log tracking thread parsing the log, so does not contain real-time data.

The number of records is limited by the value of the innodb_max_changed_pages system variable.

The `PROCESS` privilege is required to view the table.

It has the following columns:

Column	Description
SPACE_ID	Modified page space id
PAGE_ID	Modified page id
START_LSN	Interval start after which page was changed (equal to checkpoint LSN)
END_LSN	Interval end before which page was changed (equal to checkpoint LSN)

This page is licensed: CC BY-SA / Gnu FDL

Information Schema INNODB_CMP and INNODB_CMP_RESET Tables

The `INNODB_CMP` and `INNODB_CMP_RESET` tables contain status information on compression operations related to compressed XtraDB/InnoDB tables.

The PROCESS privilege is required to query this table.

These tables contain the following columns:

Column Name	Description
PAGE_SIZE	Compressed page size, in bytes. This value is unique in the table; other values are totals which refer to pages of this size.
COMPRESS_OPS	How many times a page of the size PAGE_SIZE has been compressed. This happens when a new page is created because the compression log runs out of space. This value includes both successful operations and compression failures.
COMPRESS_OPS_OK	How many times a page of the size PAGE_SIZE has been successfully compressed. This value should be as close as possible to COMPRESS_OPS. If it is notably lower, either avoid compressing some tables, or increase the KEY_BLOCK_SIZE for some compressed tables.
COMPRESS_TIME	Time (in seconds) spent to compress pages of the size PAGE_SIZE. This value includes time spent in compression failures.
UNCOMPRESS_OPS	How many times a page of the size PAGE_SIZE has been uncompressed. This happens when an uncompressed version of a page is created in the buffer pool, or when a compression failure occurs.
UNCOMPRESS_TIME	Time (in seconds) spent to uncompress pages of the size PAGE_SIZE.

These tables can be used to measure the effectiveness of XtraDB/InnoDB table compression. When you have to decide a value for `KEY_BLOCK_SIZE`, you can create more than one version of the table (one for each candidate value) and run a realistic workload on them. Then, these tables can be used to see how the operations performed with different page sizes.

`INNODB_CMP` and `INNODB_CMP_RESET` have the same columns and always contain the same values, but when `INNODB_CMP_RESET` is queried, both the tables are cleared. `INNODB_CMP_RESET` can be used, for example, if a script periodically logs the performances of compression in the last period of time. `INNODB_CMP` can be used to see the cumulated statistics.

Examples

```
SELECT * FROM information_schema.INNODB_CMP\G
*************************** 1. row ***************************
      page_size: 1024
   compress_ops: 0
compress_ops_ok: 0
  compress_time: 0
 uncompress_ops: 0
uncompress_time: 0
...
```

Information Schema INNODB_CMPMEM and INNODB_CMPMEM_RESET Tables

The `INNODB_CMPMEM` and `INNODB_CMPMEM_RESET` tables contain status information on compressed pages in the buffer pool (see InnoDB COMPRESSED format).

The PROCESS privilege is required to query this table.

These tables contain the following columns:

Column Name	Description
PAGE_SIZE	Compressed page size, in bytes. This value is unique in the table; other values are totals which refer to pages of this size.
